SIR THOMAS MARYON WILSON BART.

No. 1

FRONTISPIÈCE

A GENERAL DICTIONARY OF ARTS AND SCIENCES: OR, A Complete System of Literature.

Containing, among other BRANCHES of LEARNING,

AGRICULTURE	ETHICS	HYDROSTATICS	PAINTING
ALGEBRA	FLUXIONS	LAW	PERSPECTIVE
ANATOMY	FORTIFICATION	LOGIC	PHILOLOGY
ARCHITECTURE	GARDENING	MARITIME AND	PHILOSOPHY
ARITHMETIC	GAUGING	MILITARY AFFAIRS	PHYSIC
ASTRONOMY	GEOGRAPHY	MECHANICS	RHETORIC
BOTANY	GEOMETRY	MERCHANDIZE	SCULPTURE
CHEMISTRY	GRAMMAR	METAPHYSICS	STATICS
CHRONOLOGY	GUNNERY	MUSIC	STATUARY
COMMERCE	HISTORY	NAVIGATION	SURGERY
COSMOGRAPHY	HUSBANDRY	OPTICS	THEOLOGY, &c.

POETRY, CRITICISM, GRAMMAR, and THEOLOGY,

By the Reverend **JAMES SCOTT, M. A.**

FELLOW of TRINITY-COLLEGE, CAMBRIDGE.

The MATHEMATICAL BRANCHES

By **Mr. CHARLES GREEN,**

Late OBSERVER at the ROYAL OBSERVATORY, GREENWICH.

NAVAL and MARINE AFFAIRS, and NAVAL ARCHITECTURE,

By **Mr. WILLIAM FALCONER,**

AUTHOR of the SHIPWRECK, and PURSER in the ROYAL NAVY.

BOTANY and GARDENING,

By **Mr. JAMES MEADER,**

GARDENER to the Right Hon. the EARL of CHESTERFIELD.

And the Other BRANCHES of LITERATURE,

By a SOCIETY of GENTLEMEN, who are LOVERS and ENCOURAGERS of Science.

L O N D O N:

Printed for S. CROWDER, at the LOOKING-GLASS, in PATER-NOSTER-ROW;
And Sold by all other Bookfellers in GREAT-BRITAIN and IRELAND.

MDCCLXV.

By Mr. James M. A. D. E.

TO THE PUBLIC.

AS there are already several Dictionaries of Arts and Sciences extant, it may perhaps seem unnecessary to trouble the World with another. But we flatter ourselves that this Objection will vanish when it is remembered that, notwithstanding what has been already performed, there is still ample room for presenting the Public with a Work of this kind far superior to any Dictionary yet known in the Republic of Letters.

If this be granted, the only Question remaining will be, Whether the Authors are equal to the task, and capable of putting into the Hands of their Readers a System of Literature, in which the various Branches are more fully explained, and the different Arts and Sciences enriched with more Discoveries, and more important Observations, than those of any other Performance of the same Kind?

In order to answer this Question, we would beg Leave to observe, that several of the Gentlemen concerned in this Work are already known in the Republic of Letters; and that their Labours have more than once obtained the Approbation of proper Judges. And as they are determined to exert their utmost Abilities on this Occasion, they have some Reason to flatter themselves that their Readers will not be disappointed.

They would also humbly hope, that it will be unnecessary to observe any thing farther with regard to the Articles relating to Poetry, Criticism, Grammar, and Theology, than that they will all be executed by the Hand of the ingenious Mr. Scott, Fellow of Trinity-College, Cambridge.

Astronomy, in all Works of this nature, is, perhaps, more defective than any other Science. Nor will this appear surprizing, when it is remembered, that the Persons who have hitherto undertaken the Astronomical Articles have not been resident at the Royal Observatory at Greenwich, and consequently could not have recourse to those valuable Instruments and Machines necessary for elucidating that important Branch of Science. These Instruments and Machines have been furnished by the State at an immense Expence, and are not to be equalled in any Part of Europe. Mr. Green, who resided many Years at the Royal Observatory, as Observer, with the late eminent Royal Astronomers Dr. Bradley and Mr. Bliss, in consequence of his Office had the chief Use of these Instruments, together with free Access to the Writings of his Predecessors, whose Discoveries have done so much Honour to their Country; the Reader may, therefore, be assured that the Astronomical Articles will excel any hitherto published: And that among several other valuable Improvements, the twelve Plates of the Zodiac will be given, in which the Places of all the Stars to the fourth Magnitude, inclusive, will be inserted, as settled from actual and accurate Observations.

We

TO THE PUBLIC.

We would also beg Leave to add, that Mr. Green was lately sent to Barbadoes, by the Right Hon. the Lords of the Admiralty, as a proper Person to make Observations for fixing the Longitude of that Island, in order to determine the Merits of each Candidate for the Reward offered by Parliament for the Discovery of the Longitude.

Mr. Falconer, the Conductor of the Naval and Marine Department, is a Gentleman who has been trained to a Naval Life, whose Knowledge of that Marine is evidently displayed in a Poem called the Shipwreck, and whose Abilities, we apprehend, will be able to stand the Test of Scrutiny.

The Articles relating to Botany and Gardening have also been hitherto executed in a very superficial Manner, being merely copied from preceding Treatises. But we will venture to promise the Reader, that what relates to these Particulars will be performed in a very different Manner in this Work, Mr. Meader purposing to enrich his Department with the latest Discoveries and Improvements in that Science, confirmed by the Practice of the most eminent Botanists and Gardeners. The Abilities of Mr. Meader are so well known to the Botanists and Gardeners of these Kingdoms, that the Reader may expect to meet with ample Satisfaction.

We will venture to add, that the Articles relating to the other Arts and Sciences, will be executed in the same masterly Manner, and Improvements added in every Branch of Literature.

With all the Advantages above-mentioned, it is not to be doubted but the Public will, for their own sake, as well as to reward Merit, purchase with Avidity a Work so evidently calculated for their Advantage and Emolument, and which will reflect so much Honour on these Kingdoms.

It has been the common Practice for Authors to suppose their Readers have acquired some degree of Knowledge in the Arts and Sciences before they venture to consult their Dictionaries: And hence many have been disappointed in their Hopes of attaining a competent Knowledge of the Arts and Sciences, after they have taken the Pains to peruse assiduously such voluminous Writings. We therefore propose to pursue a very different Method: To treat of the Arts and Sciences without supposing the Reader has previously attained any Knowledge of them; and to make the various Articles mutually explain and illustrate each other. And hence we have Reason to hope, that the Dictionary we now offer to the Public will supply the Place of a Library; assist in ascertaining and improving Human Knowledge; and by increasing the Number of the truly learned, real Artists, and judicious Admirers, diffuse many new Advantages over our native Country. May Posterity, on consulting our Work say, Such was then the State of the Arts and Sciences in Great Britain! May succeeding Artists add to the Discoveries we have registered: And may this Dictionary, with the Improvements of future Writers, remain a Sanctuary to preserve Human Knowledge from the Ravages and Revolutions of distant Ages!

A B

VOL. I, N^o I.

B ning

ning of August. On the first day of this month the Jews fast, in memory of Aaron's death; and on the ninth, because upon that day the temple of Solomon was burnt by the Chaldeans, and the second temple, built after the Captivity, by the Romans. It is believed by the Jews, that those who were sent as spies into the land of Canaan, returned on this day to the camp, and engaged the people in rebellion. This too was the day on which, according to their traditions, the edict of Adrian was issued out, forbidding them any longer to continue in Judea, or even to lament the desolation of Jerusalem. They fast on the eighteenth of this month, because in the time of Ahaz the lamp of the sanctuary was on that night extinguished.

ABACK, in naval affairs, a situation of arranging the sails of a ship, in which they are flatted against the masts by the force of the wind, to effect a sudden retreat or backward motion, in order to avoid some danger discovered before the ship in a narrow channel, &c. See *BACKING the Sails*. It is likewise common to spread some sail aback in the hinder-part of a ship, when she lies in a road, to keep her at a proper distance from her anchor, that she may not run over it, and entangle it with slack cable. See *CABLE*.

ABACOT, a cap of state, in the figure of a double crown, and worn in antient times by our English kings.

ABACTORS, in law, are those who drive away, or rather steal whole herds of cattle, in which they are distinguished from fures, or thieves.

The word is Latin, and derived from *abigo*, to drive away.

ABACUS, among the ancients, implied a kind of cupboard, or buffet.

The word is Latin, and derived from the Greek *αβαξ*, which signified the same thing.

ABACUS, in architecture, is the upper member of the capital of a column, and to which it serves as a kind of crown.

Vitruvius tells us, that the abacus was originally intended to represent a square tile laid over a basket. An Athenian matron happening to place a basket, covered with a square tile, on the roof of an acanthus, which grew on the grave of a young Corinthian lady, the plant shooting up the following spring encompassed the basket, till meeting with the tile, the leaves turned back in a kind of scrolls. Callimachus, an ingenious statuary of Athens, was pleased with the beautiful novelty, and executed a capital on this plan, representing the tile by the abacus, the leaves of the acanthus by the volutes or scrolls, and the basket by the vase or body of the capital.

It still retains its original form in the Tuscan, Doric, and ancient Ionic orders; but not in those of the Corinthian and Composite; its four sides or faces being arched inwards, with some ornament, as a rose, &c. in the middle of each arch.

Scamozzi uses the word abacus to signify a concave moulding in the capital of the Tuscan pedestal.

ABACUS, among the ancient mathematicians, implied a small table strewed over with dust, on which they drew their schemes and figures.

ABACUS, in arithmetic, the common multiplication table.

ABADIR, in mythology, the stone which Saturn swallowed, believing it to be his infant son Jupiter.

ABADDON, the name by which the king of the locusts, mentioned by St. John in the Revelations, is called. The word is derived from *abad*, to consume.

ABAST, in naval affairs, further aft, or nearer the stern; as the barricade is situated abast the main-mast, *i. e.* further aft than, or behind the main-mast.

ABAPTISTON, a name given by the ancients to the perforating part of the trepan. See *TREPAN*.

The word is formed from the Greek *α priv.* and *βαπτω*, to sink under, because the instrument is by its construction prevented from sinking suddenly into the brain.

ABARTICULATION, in anatomy, the same with diarthrosis. See *DIARTHROSIS*.

ABAS, a weight used in the East-Indies for weighing pearls. It is equal to seven-eighths of the European carat.

ABASED, or *ABASSE*, in heraldry, is applied to the wings of eagles, &c. when the tip or angle tends downwards; or when the wings are shut: the natural way of them being spread, with the tip pointing to the chief, or the angles.

A chevron, a pale, a bend, &c. are also said to be abased, when their points terminate in, or below the center of the shield. And an ordinary is said to be abased, when it is placed below its proper situation.

ABATEMENT, in heraldry, implies something added to a coat of armour, in order to diminish its proper value and dignity; and indicate some dishonourable action, or stain, in the character of the bearer.

But it is very justly observed, by the last editor of Guillim's heraldry, that as arms are *insignia nobilitatis & honoris*, they cannot admit of any mark of infamy, without ceasing to be arms, and becoming badges of disgrace, which all would covet to lay aside.

ABATEMENT, in law, signifies an intrusion, or entry on lands before the heir, by a person who has no right to make such entry.

ABATEMENT, also implies the frustrating, or setting aside a suit, on account of some fault either in the matter or manner of proceeding.

ABB, among the woollen manufacturers, implies the yarn of a weaver's warp.

ABBESS, the superior of an abbey, or convent of

of nuns, over whom the pſides, and is inveſted with the ſame privileges as the abbots regular. She cannot indeed perform any of the ſpiritual offices of the prieſthood herſelf; but there are inſtances of ſome abbeſſes who have the privilege of commiſſioning a prieſt to act for them.

We read of ſome abbeſſes who had formerly a right of confeſſing their nuns; but they abuſed it ſo much, through a vain and immoderate curioſity, that it was found neceſſary to deprive them of it.

ABBEY, a monaſtery, or kind of catholic college, into which perſons retire from the world, to ſpend their time in ſloth and ſolitude. The inſtitution of theſe religious houſes was certainly firſt of all pious and uſeful; as they were intended for ſeminaries of religion, and aſylums to ſanctity: but like many other good things, they have been wretchedly perverted. Henry the VIIIth having appointed viſitors to inſpect the behaviour of the abbots and monks, found them ſo looſe and diſſolute, ſo prone to idleneſs and pride, fomenting quarrels, and ſpiriting up rebellions againſt the government, that he diſſolved the order, and converted their revenues, which amounted to 2,853,000 l. per ann. into lay fees.

Abbeys differ only from priories, as thoſe are under the government of an abbot, and theſe of a prior.

ABBOT, or ABBAT, the ſuperior of an abbey or monaſtery of monks, erected into a prelacy. The word appears to be derived from the Hebrew *ab*, which ſignifies father: from this came the Syriac or Chaldean *abba*, which we find made uſe of by St. Mark, and St. Paul in Romans viii. 15. where he ſays, “ we have received the ſpirit of “ adoption, whereby we cry *abba*, i. e. father.”

The monaſteries, in the earlier ages of Chriſtianity, were built in ſequeſtered and deſart places, fitted for ſtudy and contemplation. They were governed by men as remarkable for their plainneſs and ſimplicity as for their learning and religion; who contented themſelves with the management of their own houſes, without interfering at all in eccleſiaſtical affairs. They were ſubject to the biſhops; and if they were too remote to attend the public worſhip at the pariſh church, a prieſt was ſent to them, to adminiſter the ſacraments. But they did not always continue thus humble and unambitious: for being men of letters and ſcience, they were called from their ſolitary abodes, to oppoſe the riſing hereſies of the times; and were firſt fixed in the ſuburbs, and then in the cities themſelves. From this period they began to degenerate: they ſhook off by degrees their dependency on the biſhops, were goaded with the luſt of power, and affected titles of honour and diſtinction. Hence aroſe different orders and ſpecies of abbots; ſome were called *mitred abbots*, from the privilege of wearing the mitre, and had a full episcopopal autho-

rity within their ſeveral precincts; others were termed *croſſered abbots*, from bearing the croſier, or paſtoral ſtaff: ſome again were ſtiled *ecumenical* (i. e. univerſal) *abbots*, in imitation of the patriarchs of Conſtantinople, ſuch as John the Faſter, and Cyril his ſucceſſor; others were called *cardinal abbots*, either from being ſuperior to all others, or the principals of monaſteries, which came to be ſeparated.

Abbots are at preſent chiefly diſtinguiſhed into regular and commendatory: the former are real monks, who have taken the vow, and wear the habit of the order: the latter are ſeculars; though they have undergone the tonſure, and are obliged by their bulls to take orders, when they come of age. Tho’ they are ſaid to hold their abbey only in commendam, which means but for a few years, yet they continue, and reap the fruits of them for life, as the regular abbots do.

Before Henry the VIIIth’s time, there were in England elective and preſentative abbots; ſome mitred, and others not. The mitred were inveſted with episcopopal authority themſelves, but the others were ſubject to the dioceſan in ſpiritual matters. The mitred abbots were lords of parliament, as were ſome of the priors, who were called lords priors. Sir Edward Coke ſays there were twenty-ſeven parliamentary abbots, and two priors.

The ceremony whereby abbots are created, is called benediction, and conſiſts in cloathing him with the cowl, giving him the paſtoral ſtaff, and the ſhoes, called *pedules*.

ABBREVIATION, or ABBREVIATURE, a contraction of a word or paſſage, by dropping ſome of the letters, or by ſubſtituting certain marks or characters in their place.

The word is Latin, *abbreviatio*, and derived from *breviſ*, ſhort.

Lawyers, phyſicians, &c. uſe a great number of abbreviations, a liſt of the principal of which, in the ſeveral arts and faculties, the reader will find under the article CHARACTER.

ABBREVIATORS, officers in the Roman chancery, whoſe buſineſs is to draw the pope’s briefs, and reduce petitions granted by that pontiff into form.

ABBREVOIRS, in masonry, imply certain ſmall channels or trenches, made with a proper tool, in the joints and beds of ſtones, in order to receive the mortar or cement, and bind them the ſinner together.

ABBUTTALS. See ABUTTALS.

ABCEDARY, or ABCEADARIAN, an epithet applied to ſuch compoſitions, whoſe parts are compoſed in the order of the letters of the alphabet. The ancient Hebrew writers often compoſed their writings in this manner; and hence we have abceadarian pſalms, hymns, lamentations, &c.

ABDEST, among the followers of Mahomet, implies

implies the lotion or washing constantly used before prayer, entering the mosque, or reading the alcoran.

ABDICATION, the act whereby a magistrate, or person in some office, renounces or gives up his authority, before the legal time of his service is expired.

It differs from resignation, in being done purely and simply; whereas resignation is done in favour of a third person.

ABDICATION, among civilians, signifies a father's discarding his son, and expelling him from the family.

ABDOMEN, in anatomy, a cavity of the human body, containing many of its principal parts, and often called the lower venter, or belly, extending from the thorax to the bottom of the pelvis.

Anatomists divide the abdomen into three anterior regions, and one posterior; the anterior are the epigastric or upper, the umbilical or middle, and the hypogastric or lower region; and the posterior is called *legio lumbaris*.

Each of these regions is likewise divided into three parts, two lateral and a middle one. Thus the two lateral parts of the epigastric region are called the right and left hypochondrium: the middle part of the umbilical region is termed umbilicus, and its lateral parts lumbi, or loins: and in the hypogastric region, the middle part is called pubes, and its two lateral parts the inguinæ, or groins.

The cavity of the abdomen contains the stomach, the alimentary duct, the mesenteric duct, mesocolon, omentum, liver, gall-bladder, spleen, pancreas, mesenteric glands, the lacteal vessels, receptaculum chyli, kidneys, renal glands, ureters, bladder, and the internal parts of generation in both sexes. See each under its proper article.

The abdomen forms a kind of oblong convexity, resembling an oval vault, separated from the cavity of the thorax by the diaphragm. It is lined on the inside by a strong but soft membrane called peritonæum, which furrows and contains all the viscera. On the outside it is guarded by the muscles called *obliqui ascendentes* and *descendentes*, together with the *rectus transversalis* and *pyramidales*.

ABDUCTION, in logic, a form of reasoning, called by the Greeks *apagoge*, in which the greater extreme is evidently contained in the medium, but the medium not so evidently in the lesser extreme. The following syllogism is of this kind:

All whom God absolves are free from sin;

But God absolves all who are in Christ:

Therefore all that are in Christ are free from sin.

Here the major is evident; but the minor, or assumption, not so, unless proved by some other proposition: as, God receives satisfaction for sin by the suffering of Christ.

ABDUCTION, in surgery, a kind of fracture, where the bone being entirely broken near a joint, the two stumps recede considerably from each other. See **FRACTURE**.

ABDUCTOR, or **ABDUCTENT**, an epithet applied to several muscles of the human body, on account of their office, which is that of pulling back, or opening the parts to which they are fixed.

ABDUCTOR auricularis, or of the little-finger, arises from the annular ligament, and the third and fourth bones of the carpus in the second rank, and is inserted into the first bone of the little finger. It serves to draw that finger from the rest, and also to bend it a little.—In some subjects it appears divided into two or three muscles, consisting of so many different series of fibres.

ABDUCTOR indicis, or of the fore-finger, arises from the inside of the bone of the thumb, and is inserted into the first bone of the fore-finger, which it draws from the rest towards the thumb.

ABDUCTOR minimi digiti manus. The same with *abductor auricularis*. See **ABDUCTOR auricularis**.

ABDUCTOR minimi digiti pedis, or of the little-toe, arises from the outside of the os calcis, near the exterior bone of the metatarsus, and is inserted laterally into the outside of the second bone of that toe, which it pulls from the rest.

ABDUCTOR oculi, or of the eye, is one of the four recti, or of the straight muscles, arising from the bottom of the orbit, and spread over the first proper tunica; serving to draw the eye towards the outer canthus.

ABDUCTOR pollicis, called also *thumb*, arises from the annular ligament, and first bone of the carpus; from whence passing to the thumb, it forms that fleshy body called *mons lunæ*: it draws the thumb from the fingers.

ABDUCTOR pollicis pedis, or of the great-toe, arises from the inside of the os calcis, and the greater os cuneiforme; and is inserted into the outside of the exterior os sesamoideum pollicis: it draws the great-toe from the rest.

ABELE, in botany. See the article **POPLAR-TREE**.

ABELIANS, **ABELONIANS**, or **ABELOITES**, a sect of heretics during the reign of Arcadius, near Hippo in Africa, whose distinguishing tenet was to marry, and yet live in a professed abstinence.

The learned have taken great pains to ascertain the reason of this denomination; but after all their labours, it appears that they took their name from Abel, for no other reason than because, like that patriarch, they had no issue.

ABERRATION, in astronomy, an apparent motion of the fixed stars, first observed by Dr. Bradley, royal professor of astronomy.

That able astronomer, in the year 1725, together with M. Molineux, began a series of new observations,

tions, similar to those which Dr. Hook communicated to the public about fifty years before, in order, if possible, to discover the parallax of the earth's annual orbit.—The success of the undertaking greatly depended on the accuracy of the instrument, for which they were obliged to the ingenious Mr. Graham, who completed Mr. Molineux's parallax sector of twenty-four feet and a half, about the end of November, 1725; and on December 3, following γ Draconis was for the first time observed at Kew, as it passed near the zenith of that place. Similar observations were made on the fifth, eleventh, and twelfth days of the same month; when they thought it was needless to continue the observations any longer at that season, it being part of the year when no sensible difference of the parallax of that star could be expected.—Dr. Bradley, however, whose natural genius was continually prompting him to make observations, remaining at Kew, adjusted the instrument as usual, and observed the same star on December 17; when, in comparing the last with his former observations, he found it had passed more southerly that day than when observed before.—He attributed the cause of this appearance to the uncertainty of the observations; and concluded, that either this or the foregoing were not so exact as they before had supposed; for which reason, on December the 20th, they repeated the observations again, in order to determine from whence this difference proceeded; and found the star now passed more southerly than before: about the 26th of March following they found the star $26''$ more southerly than at the first observation; after which it was observed to be stationary for some time; but about the middle of April it appeared to be returning back: and about the beginning of June it passed at the same distance from the zenith as it had done in December, when first observed. In September following, it appeared $39''$ more northerly than it was in March; the contrary way to what it ought to appear by the annual parallax of the stars. From September the star returned towards the south, till it arrived in December to the same situation it was in at that time twelve months, allowing for the difference of declination arising from the precession of the equinox. This was a sufficient proof to convince them that the cause of this apparent motion of the star was not owing to the instrument; and to find one adequate to the effect seemed a difficulty. A nutation of the earth's axis first offered itself on this occasion, but was soon found insufficient: for tho' the change of declination of γ Draconis might have been accounted for; yet it would not, at the same time, agree with the phenomena in the other stars; particularly in a small one almost opposite in right ascension to γ Draconis, at nearly the same distance from the north pole of the equator; for tho' the star seemed to move the same way as a nutation of the earth's axis would have made it; yet it changed its

declination but about half as much as γ Draconis in the same time, as appeared upon comparing the same observations made upon the same days at different seasons of the year. This plainly proved that the apparent motion of the star was not occasioned by a real nutation; since, if that had been the case, the alterations in both stars must have been nearly equal.

The great regularity of the observations left them now no room to doubt, but that there was some regular cause that produced this unexpected motion, which did not depend on the uncertainty or variety of the seasons of the year. Upon comparing the observations with each other, it was discovered that, in both the before-mentioned stars, the apparent difference of declination from the maxima was always nearly proportionable to the versed sine of the sun's distance from the equinoctial point. This was an inducement to think that the cause, whatever it was, had some relation to the sun's situation with respect to these points. But not being able to frame any hypothesis at that time, sufficient to solve all the phenomena, and being very desirous to search a little farther into this matter, Dr. Bradley began to think of erecting an instrument for himself at Wansted, (which instrument is now at the Royal Observatory,) that, having it always at hand, he might, with the more ease and certainty, enquire into the laws of this new motion. Accordingly, by the contrivance and help of the same ingenious Mr. Graham, his instrument was fixed up the 10th of August 1727. As the place where his instrument was hung in some measure determined its radius, (which was $12\frac{1}{2}$ feet); so it likewise determined the length of the arc or limb, on which the divisions were made to adjust it; for the arc could not conveniently be extended farther than to reach $68\frac{1}{2}^\circ$ on each side the zenith. This indeed was sufficient, since it gave him an opportunity of making choice of several stars, very different both in magnitude and situation; there being more than two hundred inserted in the British Catalogue, that may be observed with it.

He had not been long observing before he perceived, that the notion they before had entertained of the stars being farthest north and south when the sun was about the equinoxes, was only true of those that were near the solstitial colour. And after he had continued to observe some months, he discovered what he then thought to be a general law observed by all the stars, namely, that each of them became stationary, or was farthest north or south when it passed over his zenith at six of the clock, either in the morning or evening. He perceived likewise, that whatever situation the stars were in with respect to the cardinal points of the ecliptic, the apparent motion of every one tended the same way, when they passed his instrument about the same hour of the day or night; for they all moved

southward while they passed in the day, and northward when in the night: so that each was farthest north when it came about six o'clock in the evening, and farthest south when it came about six o'clock in the morning.

Though he afterwards discovered that the maxima in most of these stars do not happen exactly when they pass at those hours; yet, not being then able to prove the contrary, and supposing that they did, he endeavoured to find out what proportion the greatest alterations of declination in different stars, bore to each other; it being very evident that they did not all change their declination equally. — It has been already mentioned, that it appeared from observation, that γ Draconis altered its declination about twice as much as the aforementioned small star, almost opposite to it: but examining the matter more particularly, he found that the greatest alteration of declination of those stars was as the sine of the latitude of each respectively. This made him suspect that there might be the like proportion between the maxima of other stars; but here he found observations to disagree with such an hypothesis, and deferred any farther enquiry till he should have made a series of observations in all parts of the year.

When the year was completed, and he had thoroughly examined and compared his observations together, he was convinced that the apparent motion of the stars was not owing to a nutation of the earth's axis, nor to any alteration in the plumb-line with which the instrument was constantly rectified. Refraction was also considered; but here also nothing satisfactory appeared. At last this ingenious astronomer conjectured, that all the phenomena hitherto mentioned proceeded from the progressive motion of light, and the earth's annual motion in its orbit; for if light be propagated in time, he perceived that the apparent place of a fixed object, would not be the same when the eye is at rest, as when it is moving in any other direction than that of a line passing through the eye and object; and that when the eye is moving in different direction, the apparent place of the object would be different.

The late ingenious Mr. T. Simpson of Woolwich has given us the following propositions and corollaries, in his Miscellaneous Tracts, and which fully and concisely explain this phenomenon.

PROPOSITION I.

If the velocity of the earth in its orbit bears any sensible proportion to the velocity of light, every star in the heavens must appear distant from its true place; and that by so much the more, as the ratio of those velocities approaches nearer to that of equality.

For if, while the line CG (plate I. fig. 1.) is described by a particle of light coming from a star in

that direction, the eye of an observer at T be carried, by the earth's motion, thro' T G; and CT be a tube made use of in observing; and a particle of light, from the said star, be just entering at C the end of its axis; then when the eye is arrived at n , the tube will have acquired the position vD parallel to TC, and the said particle will be at the point m , where the line CG intersects the axis of the tube; because $GT:GC::Tv:Cm$. Let now the tube, by the earth's motion, be brought into the position Ev ; then because $GT:GC::Tw:Cn$, the particle will be at n , and therefore is still in the axis of the tube: therefore when it enters the eye at G, as it has all the time been in the axis of the tube, it must consequently appear to have come in the direction thereof, or to make an angle with TH, the line that the earth moves in, equal to CTH, which is different from what it really does, by the angle GCT: whence it is evident that, unless the earth always moves in a right line directly to or from a given star (which is absurd to suppose) that star must appear distant from its true place; and the more so, as the velocity of the earth (in respect of that of light) is increased. And the same must necessarily be the case when the observation is made by the naked eye; for the supposition and use of a tube neither alters the real nor apparent place of the star, but only helps us to a more easy demonstration.

PROPOSITION II.

To find the path which a star, thro' the aforesaid cause, in one entire annual revolution of the earth, appears to describe.

Let ATBA (plate I. fig. 2.) be the orbit of the earth; S the sun in one focus; F the other focus; T the earth moving in its orbit from A towards B; DT n a tangent at T; and SD, FE perpendiculars thereto: Let $QmKRQ$ be part of an indefinite plane parallel to that of the ecliptic, passing thro' R the centre of the given star; and take T n to TR, as the velocity of the earth in its orbit at T, to that of a particle of light coming from the said star: Let T m be parallel to nR ; P nV perpendicular to AB; and QRK parallel to P nV : Then from the foregoing proposition it is manifest, that a ray of light coming from R to the earth at T, will appear as if it proceeded from m , where the line T m , produced, intersects the said parallel plane; and therefore, because T m is parallel to R n , and any parallelogram, intersecting two parallel planes, cuts them alike in every respect, it is evident that R m must be equal to T n , and Q Rm to V nD ; wherefore, since D and P are equal to two right angles, DSP and DnP must be equal, also, to two right angles, and consequently Q Rm ($=VnD$) $=DSP = AFE$. But T n or R m , expressing the celerity of the earth at T, is known to be inversely as SD; or because

SD × FE is every where the same, directly as FE; wherefore the angles AFE, QRM being every where equal, and Rm in a constant proportion to FE, the curve QmK described by m, the apparent place of the star in the said parallel plane, will, it is manifest, be similar in all respects to AEB described by the point E: but this curve is known to be a circle; therefore QmK must likewise be a circle, whose diameter QRK is divided by R, the true place of the star in the same proportion as the transverse axis of the earth's orbit is divided by either of its foci. Wherefore, sofar as much as a small part of the circumjacent heavens may, in this case, be considered as a plane passing perpendicular to a line joining the eye and star, it follows, from the principles of orthographic projection, that the star will be seen in the heavens as describing an ellipsis, whose center (as the excentricity of the orbit is but small) nearly coincides with the true place of the star, except the said place be in the pole or plane of the ecliptic; in the former of which cases the star will appear to describe a circle, and in the latter an arch of a great circle of the sphere, which, by reason of its smallness, may be considered as a right line. But these conclusions will perhaps appear more plain from the next proposition, where, for the sake of ease and brevity, the earth is considered as moving in an orbit perfectly circular, from which her real orbit does not greatly differ.

PROPOSITION III.

Having given, from experiment, the ratio of the velocity of light, to that of the earth in its orbit, and the true places of the sun and a star, to find the apparent place of the star from thence arising.

Let Ar QA (plate I. fig. 3.) be the earth's orbit, considered as a circle; S the sun in the center thereof; r the earth moving about the same from A towards Q, re a line, which being produced, shall pass through the ecliptic place of the given star, AS parallel and gr perpendicular thereto: let ef be perpendicular to the plane of the ecliptic, so that rf being equal to Sr or radius, re may be the cosine of the latitude of the given star: this being premised, it is manifest that the true place of the star from the earth will be in the direction rf, and with respect to the ecliptic, in the line re; therefore the angle Sre (=Qsr) being the difference of longitudes of the sun and star, is given by the question. Let rg, the sine of the supplement of this angle, be denoted by b, its cosine Sg, by c, the sine of the given latitude or fe, by s; and the radius Sr or fr by unity; and, while a particle of light is moving along fr, let the earth be supposed to be carried in its orbit from r to p, over a distance signified by r, and pe; pf being drawn, make rn and nm perpendicular thereto: then, because of the

exceeding smallness of pr, it may be considered as a right line, and we shall have $r(Sr) : b(rg) :: r(pr) : rb (=pn)$; and $r:r :: circ(=rn)$, by the similarity of the triangles prn, Srg, whence as $r(fp)$ to $s(fe)$ so is rb , to $rb s (=nm)$ the sine of the angle nfm: but since the sine, or tangent, of a very small arch differs insensibly from the arch itself, these values rc and rbs may be taken as the measures of the angles rfn, and nfm: hence we have, as the semiperiphery Ar Q (=3.14159, &c.) to 648000 (the seconds in 180 degrees) so is rc to $\frac{648000 r c}{3.14159, \&c.}$ (the number of seconds in the angle rfn); and as 3.14159, &c. : 648000 :: rbs : $\frac{648000 r s b}{3.14159, \&c.} = nfm$: therefore, as the earth moves from r to p, while a particle of light is describing fr, it is manifest from what has preceded, that the star will appear removed from the great circle, passing through its true place, and the pole of the ecliptic by $\frac{648000 r c}{3.14159, \&c.}$ seconds, and to have its latitude increased by $\frac{648000 r s b}{3.14159, \&c.}$ seconds. Q. E. I.

COROL. I.

Hence, if C (fig. 4.) be the true place of the star, SCF its parallel of latitude, and about C, as a center, the ellipsis FPSTE, and circle FHSOF be described so, that FC may be = $\frac{648000 r}{3.14159, \&c.}$ and TC, the semiconjugate axis, in proportion thereto as s to 1; and, if the angle SCH be taken equal to the difference of longitudes of the sun and star, then in the point P, where the elliptical periphery is intersected by the right line HQ, falling perpendicularly on FS, the star will appear to be posited. For as 1 (radius) : b (sine of QCH) :: CH : b × CH = HQ; but by the relation of the two curves CH:CT :: b × CH (=HQ) : PQ; that is, by construction, $1:s :: \frac{648000 r}{3.14159, \&c.} \times b : \frac{648000 r s b}{3.14159, \&c.} = PQ$; again, as 1 (radius) : c (the cosine of QCH) :: $\frac{648000 r}{3.14159, \&c.} (=CH) : \frac{648000 r c}{3.14159, \&c.} = CQ$; which expressions are the very same with those above determined.

COROL. II.

Therefore it follows, that while the sun appears to pursue his course through the ecliptic, the star will be seen as moving from F towards L and S, and so on till it hath described the whole elliptic periphery FLSTF, that its latitude will be the least at T, and its apparent longitude the greatest possible, when the angle SCH, shewing the distance of the sun and star in the ecliptic, is equal to two right ones. It also follows, that the greater axis,

axis of the ellipses, which all stars appear to describe, are equal, and found by observation to amount to $40\frac{1}{2}$ seconds of a great circle. The term $20''$, $25''$, which frequently occurs in the practical rules hereto annexed, being put for the half thereof. It follows, moreover, that the greatest aberrations, or *maxima*, in longitude, will be as the cosines of the latitudes inversely; and the *maxima* in latitude, as the sines of the same latitudes directly.

COROL. III.

Hence may also be found, the stars apparent right ascension and declination; for let ECP be the parallel of the star's declination, P the apparent place of the star, when in that parallel, make CA perpendicular to CH, ABD to SF, and BE to PC, and let HK, or the angle HCK, be any distance gone over by the earth in the ecliptic, while the star by its apparent motion moves through the corresponding distance PL: let K *mn* G be parallel to HC, and Lrv to PC: then, so far as K L is parallel to HP, the triangles GKL, CHP, must be equiangular; and therefore GL:CP::KL:HP; but KL is to HP, as LI to QP, by the property of the curve, whence it will be GL:CP::LI:QP; wherefore the sides GL, IL, CP, QP, about the equal angles GLI, CPQ, being proportional, the triangles GLI, CPQ must be similar, and therefore the angle GIL a right one; and consequently the right line SF, the locus of the point G. Therefore, as the angles *n, m, r, v*, are all given, or continue invariable; let the angle SCK, or the ecliptic distance of the sun and star be what it will, the ratio of Cm to CG, will always be given; but the ratio of CG to Cr is given: therefore the ratio of Cm to Cr is likewise given: hence because rv is parallel to CE, the ratio of Cm to Ev will be given. But Ev is the difference of the true and apparent declinations; and Cm, as the sine of the angle HCK: whence it is manifest, that the aberration of declination, at any time, is as the sine of the sun's elongation from either of the two points wherein he is, when the true and apparent declinations are the same; and therefore Cm will be to Ev, or AC to EB, the greatest aberration, as QH to Fb; that is, as the sine of HCF to the sine of PCQ: but PCQ, being equal to the angle of position, is given, whose tangent, it is obvious, is to the tangent of HCF, as QP to QH, or as CT to CO, or lastly (by construction), as the sine of the star's latitude to radius: hence the angle HCF is given, from which, by help of the foregoing theorem or proportion, the required aberration of declination at any time, and in any case, may be readily obtained.

The Public are obliged to the ingenious and celebrated astronomer Dr. Bevis, for the following

PRACTICAL RULES

For finding the Aberration in longitude, latitude, declination, and right ascension.

SYMBOLS.

A, the aberration at any given time; M the greatest aberration, or maximum; $\odot$, the sun's place in the ecliptic, when the star's apparent longitude, latitude, declination, or right ascension, being the same as the true, tends to excess; P, the star's angle of position; Z, the sun's elongation from its nearest syzygy with the star, at the time of $\odot$.

For the aberration in longitude.

$\odot$ is always three signs after the star's true place in the ecliptic.

Prob. 1. To find M.

Cosine star's latit. : rad. :: $20''$: M.

Prob. 2. To find A.

Rad. : sine sun's elongat. from $\odot$:: M : A.

Otherwise, without M.

Cosin. star's latit. : sin. sun's elongat. from $\odot$:: $20''$: A.

For the aberration in latitude.

$\odot$ is always at the star's opposition to the sun.

Prob. 1. To find M.

Rad. : sin. star's latit. :: $20''$: M.

Prob. 2. To find A.

Rad. : sin. sun's elongat. from $\odot$:: M : A.

Otherwise, without M.

Rad^s. sin. star's latit. $\times$ sin. sun's elongat. from $\odot$:: $20''$: A.

Otherwise,

Cosin. star's latit. sin. sun's elongat. from $\odot$:: $20''$: A.

For the aberration in declination.

Prob. 1. To find $\odot$.

Sin. star's latit. : rad. :: tang. P : tang. Z.

Then if the star (in respect of that pole of the equator which is of the same denomination as the star's latitude) be in a sign

1. Ascending, and P be acute, Z taken from the opposite to its true place, gives $\odot$.

2. Ascending, and P be obtuse, Z added to its true place, gives $\odot$.

3. Descending, and P be acute, Z added to the opposite to its true place, gives $\odot$.

4. Descending, and P be obtuse, Z taken from its true place, gives $\odot$.

Provided in all these cases that the star's declination and latitude be both north or both south; but if one be north and the other south, then, for its true place, read opposite to its true place, and vice versa.

Prob. 2. To find M.

Sin. Z : sin. P :: $20''$: M.

Prob,

ABE

Prob. 3. To find A.

Rad. : fin. sun's elongat. from $\odot$:: M : A.

Otherwise, without M.

Rad. $\times$ fin. Z : fin. sun's elongat. from $\odot \times$ fin. P :: 20' : A.

For the aberration in right ascension.

Prob. 1. To find $\odot$.

Sin. star's latit. : rad. :: cotang. P : tang. Z.

Then, if the star (in respect of that pole of the equator, which is of the same denomination as the star's latitude) be in a sign

1. Ascending, and P be acute, Z added to its true place, gives $\odot$.

2. Ascending, and P be obtuse, Z taken from its true place, gives $\odot$.

3. Descending, and P be acute, Z taken from the opposite to its true place, gives $\odot$.

4. Descending, and P be obtuse, Z added to the opposite to its true place, gives $\odot$.

Prob. 2. To find M.

Cof. star's decl. $\times$ fin. Z : cof. P $\times$ rad. :: 20' : M.

ABE

Prob. 3. To find A.

Rad : fin. sun's elongat. from $\odot$:: M : A.

Otherwise, without M.

Cofin. star's declinat. $\times$ fin. Z : fin. sun's elongat. from $\odot \times$ cofin. P :: 20' : A.

REMARKS.

1. That φ , ω , χ , ν , ξ , π , are signs ascending in respect of the north pole, and descending in respect of the south pole of the equator. And ϖ , Ω , ϑ , ϵ , η , ζ , are ascending in respect of the south pole, and descending in respect of the north pole of the equator.

2. That if the sun's place be in that semicircle of the ecliptic which precedes $\odot$, A must be taken from the star's true longitude, latitude, declination, or right ascension, to shew the apparent; but if he be in the semicircle following $\odot$, A must be added.

3. That the rules give the values of M and A always in seconds and decimals of a degree.

From the preceding rules the following table is calculated, which will be found of the greatest use to astronomers and navigators.

A TABLE of the Aberration in right ascension of sixteen principal stars, to every ten days in the year.

Use of this Table. — Suppose the Aberration of Castor is wanted for August 18. In the angle of meeting, under Castor and against Aug. 18, is found 18'.9, which is to be subtracted (having the negative sign) from the star's mean right ascension, which gives the apparent.

ABERRATION of the planets. This is always equal to the geocentric motion of the planet during the time which light takes up in coming from the planet to us.

The following demonstration is taken nearly from a paper of Mr. Clairaut, among the Memoirs of the Royal Academy of Sciences at Paris for 1764.

It is well known that a force acting according to the diagonal of a parallelogram, is equal to two forces according to its two sides; it is likewise known, that the motion of a planet, seen from the earth, or the motion of the earth seen from a planet, are exactly the same; so that if a planet appear to move one degree a day to an inhabitant of the earth, the earth appears to an inhabitant of that planet to move just one degree also in the same time.

This supposed, let P (*fig. 5.*) be the planet, which we will regard as immovable, APT the apparent motion of the planet translated to the earth: in the interval of time in which light comes from P to T, the earth having advanced from A to T is struck by the ray of light, according to the direction PT, and also strikes the ray, according to the direction AT, with the same velocity and force, as if the ray itself had met the eye with the velocity CT; thus the eye receives two compressions of the light, one according to PT, the other according to CT: and so, by a single impression, compounded of two others, it refers the planet to the diagonal BT: but the angle PTB is equal to the angle APT, which we have taken equal to the geocentric motion of the planet; therefore the aberration is equal to the motion which the planet has during the time which light takes up in coming from the planet to the spectator's eye.

For example, light takes up $8'' 7\frac{1}{2}''$ of time in coming from the sun to us; the sun's motion in longitude, during that interval, is $20''$ of a degree, whence it follows, that the sun has constantly $20''$ of aberration in longitude; and as the aberration causes the planet to appear on the same side the earth is going, and opposite that towards which the planet appears to be moving, it follows that if the longitude, for example, of a planet be increasing, the aberration must diminish it; the same holds good of latitude, right ascension, and declination.

On this principle Mr. Clairaut constructed the following table.—It contains the aberration of the planets according to their diurnal motion, and their distance from the earth, by only adding the constant logarithm 9,5292 to those of the planet's diurnal motion in minutes, and of its distance from the earth, putting that of the sun = 10, the sum will be the logarithm of the aberration; which aberration is always to be added to the mean or computed longitude, latitude, right ascension, or declination, to obtain those positions, such as they should appear on observation, when they are de-

creasing; but to be subtracted when they are increasing.

A TABLE of the aberration of the planets in longitude, latitude, right ascension, or declination.

Planet's diurnal motion.	Distance from the earth, that of the sun being 10.

Add to the observed or apparent position, and subtract from the mean position, when they are increasing.

Subtract from the observed place, and add to the computed place, when the planet's motion is diminishing.

Although this table goes no farther than to the distance 10, equal to that of the sun, yet it may be extended *ad libitum*, by simple multiplication: For example, if a comet, twice as far from the earth as the sun, that is 20, has 1 degree of diurnal geocentric motion retrograde; take, in the column of 2, the aberration for 1 degree, which is $4'' 1$, and multiply it by 10; the product will be $41'' 0$, to be subtracted from the observed place of the comet.

We shall subjoin two tables more for the aberration, of the planets, whose use is still more easy.

Elongation, or distance, from the sun, seen from the earth.		Aberration in longitude.				Elongation		Venus
		Mars	Jupiter	Saturn				
Signs	Deg.	Sec.	Sec.	Sec.				Sec.
♈ XII	0	-36	-28	-26		Sup. 6	0	-43

	0	9	12	16

When Mercury is some degrees from his greatest digressions, his geocentric motion should be carefully had from astronomical tables or ephemerides, and his aberration be made out from the first table of the planet's aberration.

Mercury's aberration in latitude, at his descending node is $4^{\circ} \frac{1}{2}$; that of the other planets is not near so much.—The sun's aberration is constantly $20''$ in longitude; but may alter its declination $8''$ near the equinoxes, and is nothing about the solstices.—The moon's aberration never amounts to one second.

ABERRATION, in optics, a deviation of the rays of light, refracted by a spherical lens, or reflected by a spherical speculum, and therefore cannot unite in one and the same focal point. See **SPECULUM**, **LENS**, and **FOCUS**.

ABETTOR, in law, implies a person who encourages another to perform some criminal action, or who seconds and assists him in the performance itself. See the article **ACCESSORY**.

But though there may be abettors in felony, murders, &c. there can be none in treason; the law considering every individual concerned in treason as a principal.

ABEYANCE, **ABEYANCE**, or **ABBEYANCE**, in law books, signifies something that exists in expectation or remembrance only.

Thus if a church becomes vacant by the death of the incumbent, the freehold is said to be in abeyance, till a new rector, &c. is appointed and inducted; for the patron has not the fee, but merely the right of presenting to it, the freehold itself being in the incumbent thus presented, and consequently, till such presentation is made, in nobody.

ABIB, the name given by the Jews to the first month of their sacred or ecclesiastical year: it was afterwards called Nisan. It commenced at the vernal equinox, and, according to the course of the moon, by which their months were regulated, answered to the latter part of March and the beginning of April.

Before the Jews were led away captive into Egypt, their year began in the month Tifri, which is our September. But afterwards when they came out of Egypt, it was ordained by God, that the sacred year, or calendar of feasts, and ceremonies, &c. should commence in the month Abib, which is the seventh month of the civil year.

This word is Hebrew, and signifies *an ear of corn*: this month was probably so called, because at that season the first corn was ripe in Palestine.

ABIES, the fir-tree. See the article **FIR-TREE**.

AB-INTESTATE, in the civil law, is applied to a person who inherits from one who died intestate, or without a will. See **INTESTATE**.

ABISHERING, in old law books, implies the being exempt from all amercements, and transgressions of any kind.

ABJURATION, in our ancient customs, implied an oath taken by a person guilty of felony, and who had fled to a place of sanctuary, whereby he solemnly engaged to leave the realm for ever.

ABJURATION is now used to signify the renouncing, disclaiming, and denying upon oath, the pretender to have any manner of right to the throne of these kingdoms.

ABJURATION OF HERESY, the solemn recantation of some doctrine as false and wicked.

ABLACTATION, the act of weaning a child from the breast. See the article **WEANING**.

ABLACTATION, in horticulture, is a term formerly used for a particular method of grafting, called, by modern gardeners, inarching, or grafting by approach. See **GRAFTING** by approach.

ABLAQUEATION, in gardening, the art of removing the earth, and laying bare the roots of trees in winter, that they may be more readily exposed

posed to rains, snow, air, &c. which was formerly thought necessary for their future welfare; but experience has shewn it to be a dangerous practice, especially, where the trees are much exposed to the winds, particularly the south-west, which are generally the most violent: and it is in a great measure laid aside in the present practice of gardening.

ABLATIVE, in the Latin grammar, is the name of the sixth case, and peculiar to that language.

It is opposed to the dative, which expresses the action of giving, and the ablative that of taking away.

ABLUENTS, in medicine, are the same with diluters, or such remedies as dissolve and carry off acrimonious and stimulating salts, from any part of the body, especially from the stomach and intestines.

ABLUTION, in antiquity, a religious ceremony, practised by the Romans, and consisted in washing the body before they began the sacrifice.

The Romans, in all probability, learned this ceremony from the Jews; since we read in Scripture, that Solomon placed at the entry into the temple which he erected to the honour and service of the true God, a capacious laver, which the text calls a brazen sea, where the priests washed themselves before they offered sacrifice; having previously sanctified the water, by throwing into it the ashes of a victim offered in sacrifice.

The Mahometans still use the ceremony of ablu-
tion.

ABLUTION, in chemistry, signifies the washing away the salts of any body, by frequent affusions of warm water.

ABOARD, Ital. *abordo*, Fr. *aborde*, any part on the deck or inside of a ship; hence any person who ascends a ship's side, to go on the deck, or into the apartments, is said to go aboard.

ABOLITION, in a general sense, implies the act of defraying a thing, or reducing it to nothing.

ABOLITION, in law, signifies the repealing any law or statute.

ABOMASUS, or **ABOMASUM**, in comparative anatomy, one of the stomachs, or ventricles, of ruminating animals, or such as chew the cud.

All ruminating animals have four stomachs, viz. the rumen, or stomach, properly so called, the reticulum, the omasus, and the abomasus.

The abomasus, or last of the four stomachs, is vulgarly called the maw; being the receptacle where the chyle is formed, and from which the food descends immediately into the intestines.

ABOMINATION, in the sacred writings, is generally used to express idols and idolatry. Thus in Ezek. xx. 7. "Cast ye away every man the abominations of his eyes, and desire not yourselves with the idols of Egypt." And again in Exod.

viii. 26. Moses says, "We shall sacrifice the abominations of the Egyptians to the Lord." It is not at all to be wondered at that idolatry should be called an abomination, as it was accompanied with licentious ceremonies, and the vilest and most abominable practices. The Israelites, who were shepherds, are said, in Gen. xli. 34. to be an abomination to the Egyptians, because they sacrificed their idols, or their sacred animals, to which they paid divine worship. The abomination of desolation (mentioned by St. Matthew xxiv. 15. "When therefore ye shall see the abomination of desolation, spoken of by Daniel the prophet, stand in the holy place,") means the ensigns of the Roman army, on which were painted the images of animals, as well as of their gods and emperors: at the last siege of Jerusalem, which was carried on under Titus, these ensigns were lodged in the temple, when the city was taken.

ABORIGINES, in geography, a name given to the original or first inhabitants of any country, in contradistinction to colonies, or new inhabitants from some other part of the earth.

The term aborigines is famous in antiquity; and tho' at present taken as an appellative, it was originally the proper name of a certain people of Italy, who inhabited the ancient Latium, or country now called Campagna di Roma, when Æneas, with his Trojans, came into Italy.

In this sense the Aborigines are distinguished from the Janigenæ, from the Siculi, from the Grecians, and from the Latins, whose name they afterwards assumed.

Authors are greatly divided with regard to these Aborigines; some will have them to be the original inhabitants settled there by Janus, or by Cham, soon after the dispersion at Babel; some think they were originally Arcadians, parties of whom were brought into Italy at different times; and others derive this nation from the Lacedæmonians, who fled into Italy from the severe discipline of Lycurgus. Some again will have them to have been rather of Barbarian than Grecian original, and to have come either from Scythia or Gaul; while others believe they were descended from the Canaanites, who were driven out of their own country by Joshua.

ABORTION, in medicine, an untimely or premature delivery of the fœtus.

An abortion may proceed from various causes; as immoderate evacuations, violent motions, sudden passions, frights, &c. It may also happen at any time of pregnancy; but if before the second month, it is usually called a false conception.

A continual or intermitting fever generally precedes an abortion, together with a pain in the loins and head; a heaviness in the eyes; a bearing down and constriction of the abdomen; and when the time of miscarriage is just at hand, the pains are much the same with those in labour, and felt principally

especially about the os pubis, and os sacrum. The breasts, which were before turgid, now subside and become flaccid; the patient is apt to faint, and a ferous humour oozes from the uterus.

If the time of pregnancy be far advanced, so that the foetus must needs be large; if the causes of abortion were violent; if the patient be strongly convulsed; if a large hæmorrhage either precede or follow; if the patient be of a weak constitution; if the foetus be putrefied; or if the woman was never delivered of a live child; the case may be considered as dangerous: but, with other circumstances, abortion very rarely proves mortal.

Upon the first appearance of the symptoms of abortion, the patient must be put to bed, and the passions of the mind kept calm and moderate. The food should be easy of digestion. The liquor may be wine, diluted occasionally with water: but in case of a diarrhœa, large floodings, &c. the white decoction appears to be the most proper liquor. In other respects, the diet and regimen must be suited to the particular symptoms which happen to attend abortion; whether they are costiveness, a teneffus, vomiting, &c.

An habitual weakness, or laxity of the uterine vessels, should be treated as the fluor albus; but except the patient be of a thin or hectic constitution, a decoction of guaiacum, will, in this case, prove very serviceable.

When the flooding is attended with the breaking out of the waters, and violent pain at the bottom of the abdomen, the time of abortion is judged near. In this case, the use of astringents is to be omitted: as the abortion is natural or unnatural, the midwife is to perform the part adapted to a natural or unnatural birth: the same external and internal medicines, which tend to bring away the secundines, and promote lochia, being proper in both cases.

ABORTIVE, in a general sense, implies any thing which comes before its proper time, or miscarries in the execution.

ABORTIVE *velum*, that made of the skin of an abortive calf. See *VELUM*.

ABRA, a silver coin struck in Poland, and nearly equal in value to an English shilling.

ABRACADABRA, a magical word, which being written in a certain form, a certain number of times, was, in the ages of ignorance and superstition, supposed to have the virtue of a charm or amulet, in curing agues.

ABRAHAMITES, were an order of monks, who, in the ninth century, were exterminated by Theophilus for idolatry. It is the name also of a sect of heretics, who renewed the errors of Paulus and his followers.

ABRASION, in surgery, the act of wearing away the natural mucus which covers the membranes, particularly those of the stomach and intestines, by corrosive medicines, &c.

ABRASAX, or ABRAXAS, a mystical term that occurs in the antient theology and philosophy of certain heretics, particularly the followers of Basilides. Some moderns, on the credit of Tertullian and Jerome, have affirmed that this arch-heretic called the Supreme Being by the name of *Abraxas*; but this is not very probable, as Irenæus tells us, that the Basilidians gave no name whatever to the Almighty, but say that the Father of all things is ineffable, and without name.

It seems as if this word denoted Mithras, or the sun, which was the God of the Persians. For by computing the value of each letter, as the Greeks were wont to do,

A	I
Β	2
Γ	100
Δ	1
Ε	200
Ζ	1
Η	60

365

we come by the number 365, which is the number of days contained in a solar year.

In the 17th century two talismans were found, on one of which was the word *ABRACAX* in Greek capitals, and on the other, which is still to be seen in the cabinet of St. Genevieve, the following inscription: *ABPACAX. AΔONAI. ΔAIMONON. ΔΕΞΙΑΙ. ΔΥNAMEΙΣ. ΘΥΑΞΑΤΕ. ΟΥΛΙΗ. ΑΝ. ΠΑΤΕΙΝΑΝ. ΑΠΟ. ΠΑΝΤΟΣ. ΚΑΚΟΥ. ΔΑΙΜΟΝΟΣ* which is, "Abraxas, lord of demons, propitious powers, preserve Ulpus Paulinus from every evil demon." The word *Adonai* being made use of here immediately after *Abraxas*, clearly points out that it is of Oriental, and not of Greek extraction: for which reason, what Beausobre has said is rather ingenious than true, that *Abraxas* is compounded of two Greek words, of which he makes *αλπος* and *σαω*, or *σα* the other; and so proves the meaning of it to be the *beautiful*, or the *magnificent Saviour*, and applies it to the sun. Nothing has puzzled the learned more than the origin and signification of this enigmatical term: we shall present our readers with a few of their explanations, and then leave them to judge for themselves. One says that *Abraxas* is compounded of the initial letters of several words, three Hebrew, and three Greek, in the following manner:

A	stands for Ab, the father
B	Ben, the son
R	Rouach, the spirit
A	Acadofch, holy
S	Soberia, salvation
A	Apo, by
X	Xulou, the tree, or wood,

This it must be confessed is a very orthodox explanation, but so wild and improbable, that it could

never have entered into any one's head, except that of an ecclesiastic visionary. Another writer, who adopts the plan above, and improves upon it, thinks that the letters A. S. A. X. stand for *αριθμοὶ σφραγισμένοι ἐξ ἁλῆος*. There is another different account of it given by M. Bafnage, in his History of the Jews. He asserts, that the word Abraxas took its origin from the Egyptians; because there are a great number of amulets to be found, on which is an Harpocrates, the Egyptian God of Silence, sitting on the lotus, and the scourge in his hand, with the word Abraxas. This is certainly a true account of it: for the word, Abracadabra, which is recommended as a charm by Serenus Simonicus, who was a follower of Basilides, is evidently taken from Abraxas.

ABREAST, in naval affairs. On the different occasions of attack, pursuit, or retreat at sea, the squadrons or divisions of a fleet are often obliged to vary their dispositions, and yet observe a proper regularity, by sailing in right or curved lines: when they sail at a proper distance from each other, and are all equally forward, they are then said to have formed the line abreast, the commander in chief being stationed in the center; and the second and third in command, if there be any, in the center of their divisions, on each wing; there being no van or rear in the manœuvre. See *LINE ahead*.

ABRIDGING, the shortening or contracting any book, writing, &c.

ABRIDGING, in algebra, is reducing a compound equation to a more simple form. See *EQUATION*.

ABRIDGMENT, an abstract or epitome of a larger work.

Critics and students, who are commonly the greatest enemies to abridgments, pretend, that the custom of making them was not introduced till a long time after those happy ages when the arts and sciences flourished in Greece. In their opinion, abridgments were the first fruits of idleness, when those times which succeeded the fall of the empire were shrouded in the darkness of barbarism. Men of learning, say they, then only endeavoured to shorten their labours and studies, especially in reading the historians, philosophers, and lawyers, either for want of leisure or courage to peruse the originals.

Some authors have thought, that several of the books of the Old Testament are only abridgments of the books of Gad, Iddo, and Nathan, of the writings of Solomon, the Chronicles of the kings of Judah, &c. The lawyers complain, they owe to this artifice the loss of above two thousand volumes of the first writers in their profession, as Popinian, the three Sævolas, Labenus, Ulpian, Modestinus, and several others, whose names are well known. By the same means a great number of

the works of the Greek fathers, from Origen or Ireneus, down to the time of the schisms and divisions of the church, have perished: during which period a great variety of authors wrote upon the books of Scripture. The extracts which Constantinus Porphyrogenitus made from several excellent Greek and Latin historians, relating to history, politics, and morality, tho' in other respects highly commendable, have occasioned the loss of the universal history of Nicholas of Damascus, great part of the books of Polybius, Diodorus Siculus, Dionysius Halicarnassus, &c. Nor have we any room to doubt but that Justin has occasioned the loss of the entire history of Trogus Pompeius, by the abridgment he made of that work; and it may justly be said, that the same thing has happened in all other branches of literature.

It may, however, be alledged in favour of abridgments, that they are convenient for such as have neither leisure to consult the originals, ability to procure them, nor talents to understand them thoroughly. Besides, Salmasius has remarked, that the most excellent works, both among the Greeks and Romans, would infallibly have perished in the times of barbarism, had it not been for the industry of the authors of these abridgments, who have, at least, saved us some planks out of the general shipwreck, and no ways prevent our consulting the originals whenever they can be found.

ABRIDGMENT, in law, implies the shortening a plaint or declaration.

ABROGATION, signifies the repealing and abolishing a law.

ABROTANUM, southernwood, in botany. See the article *SOUTHERNWOOD*.

ABRUS, American bitter-yetch, called gliscine by Linnæus, a kind of kidney-bean, growing in the East and West-Indies, in Egypt, and other parts of the world.

It is used in the East and West-Indies, with the same intention as liquorice, and increased by seeds sown in the spring; but being a tender plant, it requires a hot-house in this climate.

ABSCCESS, in surgery, an inflammatory tumour, containing purulent matter, pent up in a fleshy part.

An abscess is always the effect of an inflammation, which may frequently be dissipated without coming to a suppuration, or before the abscess is formed.

But when the proper remedies to disperse the humour have been too long neglected, or used in vain, the utmost expedition should be used to bring the humour to maturation. The proper medicines for promoting this intention are such as increase the motion in the part, and have a tendency to create a gentle fever; such as fomentations, and stimulating medicines. Such compositions also as confine the heat excited in the part affected, by

preventing an excessive perspiration, are also proper. The simple aromatic gums, and the emollient, relaxing, and moistening medicines, are therefore proper for maturing the pus.

This method must be pursued till the abscess has acquired a sufficient degree of ripeness, which may be known by the softness of the part, and the fluctuation of the tumour when pressed; its whiteness, the remission of the pain, heat, redness, tension, pulsation, and fever; the pointed apex of the tumour, and a sense of weight succeeding the pain, are likewise signs that the pus is already formed, and fit for evacuation.

When these signs indicate the maturity of the tumour, the knife is to be introduced into its inferior, softest, whitest, and most prominent part, till the pus flowing out evinces that a sufficient penetration is made: then let the knife be raised equally upwards, so as to make a large incision; or forcing its point through the opposite part of the abscess, let the intermediate integuments be divided, taking care to avoid the fibres and vessels.

Then let the ulcer be cured by cleansing, suppurating, digestive, deterfise, and drying medicines, which must be varied according to the state of the part. See the article WOUND.

If the patient be afraid of an incision, let a caustic be applied to the part, the eschar separated, and the cure performed, in the same manner as before.

ABSCISSE, or ABSCISSA, in conic sections. See PARABOLA, ELLIPSIS, and HYPERBOLA.

ABSCISSION, in rhetoric, a figure of speech, whereby the speaker stops short in the middle of his discourse, leaving the hearer to draw what conclusion he pleases.

ABSINTHIUM, wormwood, in botany. See the article WORMWOOD.

ABSIS, in astronomy, the same with apsis. See APSIS.

ABSOLUTE, in a general sense, denotes something that is unconnected with, or independant on another.

ABSOLUTE, is also an epithet applied to things which are free from limitation, or condition.

ABSOLUTE Equation, in astronomy. See EQUATION.

ABSOLUTE Number, in algebra. See NUMBER.

ABSOLUTE Motion, }
ABSOLUTE Space, } See { MOTION.
ABSOLUTE Time, } { SPACE.
 } { TIME.

ABSOLUTION, a term synonymous with pardon or forgiveness.

Pardon is in consequence of an offence committed, and relates principally to the offender; it depends upon the party offended, and produces a reconciliation when it is sincerely asked, and sincerely granted. Forgiveness is in consequence of a crime,

and has a particular relation to the punishment which the crime deserves: it is granted either by a prince or a magistrate, and arrests the uplifted arm of justice.

Absolution therefore is in consequence of an offence or crime, and properly concerns the state of the guilty: it is pronounced either by the civil judge or the ecclesiastical minister, and reinstates the accused, or the penitent, in the rights of innocence.

ABSOLUTION, in law, is a sentence whereby the party accused is declared innocent, and consequently saved from the punishment inflicted by the laws, for the commission of the particular crime or offence with which he is charged.

The general method of trial, whether the accused were guilty or innocent, among the Romans, was generally this: After the cause had been pleaded on both sides, the prætor pronounced aloud the word *dixerunt*, the parties have said what they have said, or what they have to say. Then three billets were immediately distributed to each judge, one marked with the letter A. for absolution, another with C. for condemnation, and the third with N. L. for *non liquet*, it is not clear, to require a respite of judgment; and accordingly as there was a majority of this or that mark, the accused was absolved, condemned, or respited. When the votes were equally divided on the sides of absolution and condemnation, the accused was absolved, from a maxim supposed to be founded on the law of nature.

At Athens the practice was different; criminal causes were carried before the Heliceæ, or the tribunal of judges called Heliastræ, from *ἡλιαστρον*, the sun, because they held their assemblies in a place uncovered. When summoned by the Thesmothetes, they assembled in a large number, sometimes amounting to fifteen hundred, and gave their suffrages in the following manner: A large vessel covered with wicker was placed in the middle of the assembly, and on it two urns, one of copper and the other of wood; in the lids of those urns was a long but narrow aperture, in the form of a parallelogram or long square. The wooden urn was called *κρυπτή*, being that into which the judges cast the suffrages for condemning the accused; while that of copper was named *ἀκρυβής*, and received the suffrages of absolution.

As soon as the cause had been pleaded, two pieces of copper were distributed to each of those magistrates, the one plain, and the other with a hole in it; the former implied absolution, and the latter condemnation; and according to the majority of pieces found in the one or the other of these urns, the party accused was absolved or condemned.

ABSOLUTION, in the canon law, implies the ministerial power of remitting sins, vested by Christ in the apostles, and from them derived to the church.

This

This is all that the primitive church ever pretended to, leaving the absolute, sovereign, independent, irrevocable power of absolution to God alone.

The ancients enumerated five kinds of absolution: 1. Baptism. 2. The eucharist. 3. The word and doctrine. 4. The imposition of hands and prayer. 5. The reconciliation to the communion of the church, by a relaxation of her censures.

The two first may be called sacramental; the third declaratory; the fourth precatory; and the fifth judicial. The first had no relation to penitential discipline, being never given to persons who had once received baptism. The second had some relation, but did not solely belong to it; for it was given to all baptized persons in general, whether they had ever fell under penitential discipline or not: and in both cases was called *το τῆς ἁγίας*, the perfection or consummation of a Christian. By the third, the ministers of the church made public declaration to men of the terms of reconciliation and salvation. The fourth was used as a concomitant of most other absolutions; and by the fifth penitents were finally restored to the peace and full communion of the church.

But during the first ages of the church, the form of absolution always run in this manner, *Christi absolvo thee*; the indicative form, *I absolve you*, having never been heard of till the twelfth century, a little before the time of Thomas Aquinas, who was the first person that wrote in defence of it.

The judicious Hooker, speaking of the abuse of absolution in the Romish church, says, "They strangely hold, that whatsoever the penitent doth, his contrition, confession, and satisfaction, have no place of right to stand as material parts of this sacrament, nor consequently any such force as to make them available for the taking away of sin, in that they proceed from the penitent himself, without the privy of the minister, but only as they are enjoyed by the minister's authority and power: — except therefore the priest be willing, God hath by promise hampered himself so, that it is not now in his own power to pardon any man: — he hath no answer to make but such as that of the angel to Lot, I can do nothing." This able writer then describes the true nature and effects of absolution, and adds, "The sentence therefore of ministerial absolution hath two effects: touching sin, it only declareth us freed from the guiltiness thereof, and restored unto God's favour; but concerning right in sacred and divine mysteries, whereof through sin we are made unworthy, as the power of the church did before, effectually bind and retain us from access unto them; so, upon our apparent repentance, it truly restoreth our liberty, looseth the chains

"wherewith we were tied, remiteth all whatsoever is past, and accepteth us no less returned, than if we had never gone astray."

ABSORBENT Vessels, in anatomy, are those which absorb the fluids of the body. Thus the lacteals, whose mouths open into the intestines, and imbibe the nutritious juice, are called by this name. The pores diffused over the whole body are sometimes also styled absorbent vessels, because they imbibe the air, effluvia, &c.

ABSORBENT Medicines, among physicians, are such as have the property of drying up the redundant humours, whether taken inwardly, or applied externally to ulcers, &c.

All the testaceous powders, boles, chalk, calcined bones, magnesia alba, &c. are esteemed powerful absorbents.

ABSORPTION, in the animal economy, implies the act whereby the open orifices of the vessels imbibe the juices they meet with in the cavities of the body.

ABSTEMIOUS, an epithet applied to persons who use great temperance both in eating and drinking, especially those who abstain from wine.

The word is Latin, *abstemius*, and compounded of *abs*, from, and *temetum*, wine.

ABSTERGENTS, in the materia medica, are remedies of a saponaceous nature, capable of dissolving resinous concretions. Castellus has confounded them with abluents.

ABSTINENCE, *abstinentia*, the refraining from something we have a propensity to, or in the enjoyment of which we find satisfaction.

Several are of opinion, that mankind before the flood abstained from flesh and wine, because the Scriptures expressly mention, that Noah, after the Deluge, began to plant the vine, and that God permitted him to use the flesh of animals for food; whereas he had given Adam only the fruits and plants of the earth for his sustenance. There are however many learned interpreters who maintain the contrary, and believe, that mankind before the Deluge did not deny themselves the pleasures of either wine or animal food. Indeed the Scriptures themselves assure us, that all flesh had corrupted his way; and therefore tho' the Almighty did not allow Adam to use either flesh or wine, his impious descendants gave themselves little trouble to observe the prohibitions of their Maker.

The priests among the Jews were commanded by the law to abstain from wine during the whole time they were engaged in the service of the temple; and the same prohibition extended to the Nazarites, as long as they continued such.

The ancient athletes observed a perpetual abstinence from all kind of sensual pleasures, in order to render their bodies more hardy and robust.

When Orpheus had softened the manners of men, he established a kind of life since called the Orphic;

Orphic; one of the chief tenets of which was, not to eat the flesh of animals. In all probability, Orpheus, after making the first people sensible of the laws of society, restrained them from eating meat, in order to wean them entirely from their primitive fierceness: and this practice being afterwards adopted by such as were desirous of leading a more perfect life than others, the ancients called it *Ορφέος Βίος*, the Orphic life, which is mentioned by Plato in his *Epinomis*, and in the sixth book of his *Laws*.

The Phenicians and Assyrians, who were neighbours to the Jews, had their sacred fasts. The Egyptians, according to Herodotus, sacrificed a cow to Isis, after they had prepared themselves by fasting; and he attributes the same custom to the women of Cyrene. Among the Athenians, the Eleusinian mysteries, as well as the Thesmophores, were attended with rigorous fastings, especially among the women, who passed a whole day sitting on the ground in a mourning habit, and without taking any sustenance. They had also settled fasts at Rome, in honour of Jupiter; and historians also mention those of Julius Cæsar, Augustus, Vespasian, Marcus Aurelius, &c.

The Pythagoreans, or at least those among them who professed the greatest perfection, and valued themselves for having attained to the greatest degree of their master's theory, never tasted either flesh or fish. This abstinence from whatever had life, was a consequence of the metempsychosis; tho' it is difficult to say from whence Pythagoras imbibed the aversion he had to beans, mallows, wine, &c.

ABSTINENCE, in medicine, has a very extensive signification: for by this word we understand a refraining from all succulent aliments.

Tho' abstinence is not sufficient to cure diseases, yet it greatly assists the operation of the medicines, and is a preservative against many disorders, especially those which result from gluttony.

We ought to regulate the quantity of aliments we take, according to the loss of substance we sustain by means of exercise, and the time during which perspiration is more or less plentiful; and also to abstain from such aliments as we have observed to disagree with our constitution.

The kinds of abstinence to which we ought to confine ourselves, both in sickness and health, should be regulated by the laws of diet and regimen. See the article *REGIMEN*.

Several writers relate wonders of the effects of abstinence in the cure of many disorders, and in protracting the time of life. The noble Venetian Cornaro, after every method had proved in vain, so that his life was despaired of at forty, recovered, and lived to near an hundred, merely by abstinence.

It is indeed surprising, to what a great age the

primitive Christians of the east, who retired from the persecution into the deserts of Arabia and Egypt, lived, healthy and cheerful, on a very little food. Cassian assures us, that the common quantity for twenty-four hours was twelve ounces of bread, and mere water; and that St. Anthony, on that portion only, lived to the age of an hundred and five years; James the hermit, an hundred and four; Arsenius, tutor to the emperor Arcadius, an hundred and twenty; St. Epiphanius an hundred and fifteen; Simeon the Stylite, an hundred and twelve; and Romauld, an hundred and twenty.

We can indeed equal, nay even excel, these instances of longevity, from the same cause, at home. Buchanan tells us, that one Laurence preserved his life to an hundred and forty, by the mere force of temperance and labour; and Spotswood mentions one Kentigern, who lived to an hundred and eighty-five by the same means. See *LONGEVITY*.

Most of the chonical diseases, the infirmities of old age, and the untimely deaths of Englishmen, are, according to Dr. Cheyne, owing to repletion, and may be prevented by abstinence.

Among the brute creation, we see extraordinary instances of long abstinence. It is natural for various species to pass four, five, or six months every year, without either eating or drinking. The tortoise, dormouse, serpent, &c. are observed to retire regularly, at certain seasons, to their respective cells, and there hide themselves; some get into the caverns of rocks, or ruins; some dig holes under ground; some retire to the woods, and lay themselves up in the clefts of trees; and others bury themselves under water.

The serpent kind bear abstinence to a miracle. We have seen rattle-snakes that have subsisted many months without food, and still retained their vigour and fierceness. Dr. Shaw mentions, in his travels, a couple of cerastes, a sort of Egyptian serpent, which had been kept five years in a bottle close corked, without any sort of food, unless a small quantity of sand, wherein they had coiled themselves up in the bottom of the vessel, may be reckoned such; yet when he saw them, they had just cast their skins, and were as brisk and lively as if just taken. In short, several species of birds, almost the whole tribe of insects, and many among the other tribes, are able to subsist during the winter, without food, and many of them without respiration. This furnishes an admirable instance of the wisdom of the Creator: the proper food of these creatures, especially of the insect tribe, being then wanting, a provision is made for them to live without it. When the fields are divested of their flowery carpet, and the trees and plants are stripped of their fruits, what would become of such animals as subsist wholly on the produce of the spring and summer? and when the air is

grown rigid and chilly with the frost, what would become of those tender species, which are impatient of cold? To prevent the total destruction and extirpation of many species of animals, the author of nature has provided, that creatures thus bereaved of their food, should be likewise impatient of cold, to lead them thus to shelter themselves from danger; and that when arrived in a place of security, the natural texture and viscosity of their blood should dispose it, by a farther degree of cold, to stagnate in the vessels: so that the circulation stopping, and the animal functions being in a great measure suspended, there is no sensible waste or consumption of parts, but they remain in a kind of drowsy neutral state, between life and death, till the warm fun revives both them and their food together, but thawing at once their congealed juices and those of the vegetables on which they feed. The sleep of such animals is but very little different from death, and their waking from a resurrection; for if life doth not consist in a circulation of the blood, we know not in what it does consist.

Hence it is no wonder that tortoises, dormice, &c. are found as fat and fleshy, after some months abstinence, as before. Sir George Ent weighed his tortoise several years successively, at its going to earth in October, and its coming out again in March, and found that out of four pounds four ounces, it only used to lose about one ounce. Nor are there wanting instances of men who have passed several months in as strict abstinence as other creatures. The records of the Tower mention a Scotman imprisoned for felony, and strictly watched in that fortress for six weeks, during which interval he had not the least sustenance of any kind, and on that account obtained his pardon. The German Ephimerides speak of a woman called Martha Taylor, who, from a blow on the back, lost her appetite to such a degree, that the only sustenance she took during thirteen months, was only a few drops from a feather. This was indeed a morbid and unnatural case, for she slept very little during the whole interval.

We may add the instance of S. Chilton of Tinsbury, near Bath, who, in the years 1693, 1694, and 1695, slept sometimes four months, and sometimes above six together, with very little food, and six weeks with nothing more than a small quantity of tent, conveyed with a quill into his mouth, through a hole in his teeth.

It is added, that in most of the instances of long abstinences related by naturalists, there were apparent marks that the texture of the blood was similar to that of summer beasts and insects. It is indeed no improbable opinion, that the air itself may furnish some kind of nutriment; for it is certain there are substances of all kinds, animal, ve-

getable, &c. floating in the atmosphere; which must be continually taken in by respiration.

ABSTINENTS, a name given to a sect of Heretics, who sprang up in France and Spain, at the end of the third century, when the Christians were persecuted by Dioclesian and Maximian. They were a kind of Gnostics, or Manicheans: they decried marriage, condemned the use of meats, as if created by the Devil, and degraded the Holy Spirit into the class of created Beings.

ABSTRACT Idea, among logicians, implies the idea of some general quality or property considered simply in itself, without any regard to a particular subject: thus magnitude, equity, &c. are abstract ideas, when we consider them as detached from any particular body or person.

Abstract ideas are of two kinds, absolute and relative. The former contain general and universal conceptions of things considered in themselves, as being, essence, existence, act, power, substance, mode, &c. The latter compare several things, and consider merely the relations of one thing to another, without considering whether the subjects of those relations be corporal or spiritual; such are our ideas of cause, effect, likeness, unlikeness, subject, object, identity, &c.

All things that exist, says Mr. Locke, being particulars, it may perhaps be thought reasonable, that words, which ought to be conformable to things, should be so too: but we find it quite the contrary; for most words in all languages are general terms; nor has this been the effect of neglect or chance, but of reason and necessity.

But since all things that exist are only particular, how came we by general terms? or where do we find those general natures they are supposed to represent? Words become general, by being made the signs of general ideas: and ideas become general, by separating from them the circumstances of time, place, and other ideas that may determine them to that or this particular existence. By this method of abstraction they are rendered capable of representing more individuals than one, each of which having a conformity to that abstract idea, is of that sort.

But it may not be amiss to trace our notions and names from their beginning, and observe by what degrees we proceed from our infancy, and enlarge our ideas to general ones. It is evident, that the first ideas children acquire are only particular, as that of nurse or mother, and the names they give them are confined to those individuals; afterwards observing, by time and acquaintance, that there are a great many other things in the world that resemble them in some common agreement of shape and other qualities, they frame an idea which they find those many particulars include; to this idea they give, with others, the name man, for example; in this they make nothing

thing new, but only leave out of the complex idea they had of Peter, John, &c. that which is peculiar to each, and retain only what is common to all; and thus they acquire a general name, and a general idea. By the same method they advance to more general names and notions; for observing several things that differ from their idea of man, and cannot therefore be comprehended under that name to agree with man in some certain qualities; and uniting them into one idea, they have another more general idea, to which giving a name, they make it of a more comprehensive and extensive nature; thus, by leaving out the shape, and some other proportions signified by the name man, and retaining only a body with life, sense, and a spontaneous motion, they form the idea signified by the name animal. By the same way they proceed to body, substance, and at last to being, thing, and such universal terms, which stand for any ideas whatsoever.

Abstract ideas are not however so obvious or easy to children, or the yet unexercised mind as particular ones. If they seem so to men, it is only because they are rendered so by constant and familiar use. For when we attentively reflect upon them, we shall find that general ideas are fictions and contrivances, that carry difficulties with them, and do not so easily offer themselves as we are apt to imagine. Does it not, for example, require some pains and skill to form the general idea of a triangle; since it must be neither oblique nor rectangular, neither equilateral nor scalenon, but all, and none of these at once. In effect, it is something imperfect, which cannot exist; an idea wherein some parts of several different and inconsistent ideas are put together. It is true the mind, in this imperfect state, has need of such ideas, and hastens to them for the convenience of communication and enlargement of knowledge, to which it is naturally very much inclined. There is however reason to suspect that such ideas are marks of our imperfection; at least that the most abstract ideas are not those which the mind is first and most easily acquainted with.

In the next place, it must be considered what is the proper signification of general words. It is evident they do not barely signify one particular thing; for then instead of being general terms, they would be proper names: neither do they signify a plurality, for then man and men would signify the same. General words therefore signify a sort or species of things; and consequently the essences of the sort or species of things, are nothing else but abstract ideas. The measure, or boundary, of each sort, or species, whereby it is constituted that particular sort, and distinguished from others, is what we call essence, which is nothing but that abstract idea to which the name is annexed; whence it is easy to observe, that the essences of the species of things, and consequently the sorting of things, is the

workmanship of the understanding that abstracts and makes those general ideas.

These essences or abstract ideas are distinct species. Thus a circle is as essentially different from an oval, as a sheep from a goat; and rain is as essentially different from snow, as water from earth; that abstract idea, which is the essence of the one, being impossible to be communicated to the other. And thus any two abstract ideas, that in any part vary from one another, with two distinct names annexed to them, constitute two distinct sorts, or, if you please, species, as essentially different, as any two the most remote or opposite in the world. Propositions concerning any abstract ideas, that are once true, must needs be eternal verities.

Such is the excellent Mr. Locke's account of abstract ideas; and it is now generally allowed, that the mind has the power or faculty of forming abstract ideas, or general notions of things. The late learned Dr. Berkley has however called this doctrine in question. "I will not affirm, says that ingenious writer, that other people have not this wonderful faculty of abstracting their ideas; but I am confident I have it not myself. I have indeed a faculty of imagining or representing to myself the ideas of those particular things I have perceived, and of variously compounding or dividing them. I can imagine a man with two heads, or the upper parts of a man joined to the body of a horse. I can consider the hand, the eye, the nose, each by itself abstracted, or separated from the rest of the body; but then, whatever hand or eye I imagine, it must have some particular shape and colour. So likewise the idea of a man, that I frame to myself, must be either a white, or a black, or a tawny, a strait, or a crooked, a tall, or a low, or a middle-sized man. I cannot by any effort of thought conceive, the abstract idea of a triangle above described; and it is equally impossible for me to form the abstract idea of motion, distinct from the body moving, and which is neither swift nor slow, curvilinear, nor rectilinear; and the same may be said of all other abstract general ideas whatsoever."

Words, according to Mr. Locke, become general by being made the signs of general ideas. But Dr. Berkley says, words become general by being made the sign, not of an abstract general idea, but of several particular ideas, any one of which it indifferently suggests to the mind. Thus, when it is said, for example, "The change of motion is proportional to the impressed force;" or, "Whatever has extent is divisible;" the propositions are to be understood of motion and extension in general; but it will not therefore follow, that they suggest to my thoughts an idea of motion without a moving body, or any determinate direction, velocity,

ocity, &c. or that we must conceive an abstract general idea of extension, which is neither line, surface, nor solid; nor great, nor small, black, white, nor red, &c. It only implies that whatever motion we consider, whether it be swift or slow, perpendicular, horizontal, or oblique, or in whatever object, the axiom concerning it holds equally true; as does the other of any particular extension, it matters not whether it be a line, surface, or solid; whether of this or that magnitude, figure, &c.

ABSTRACT Terms, in logic, are such as denote those objects which exist only in the imagination. Thus beauty and ugliness are abstract terms.

There are some objects that please and appear agreeable to us; whereas, on the contrary, there are others that affect us in a very disagreeable manner: the former we call beautiful, and the latter ugly; and yet there are no such real substances in nature, as beauty and ugliness: they subsist in our imagination only.

ABSTRACT, or pure *Mathematics*, are those branches which treat of magnitude, or quantity, considered absolutely, and in general, without restriction to a particular part. Geometry, Algebra, and Arithmetic, are therefore abstract Mathematics.

ABSTRACT Numbers, are assemblages of units considered in themselves, and not applied to denote any collections of particular and determined things. Thus, 5, is an abstract number if considered simply in itself; but if we say 5 feet, or 5 pounds, then 5 becomes a concrete number.

ABSTRACTION, an operation of the mind, whereby we separate things naturally connected together, and consider each single relation, or property of the subject singly by itself.

This operation is performed three ways: 1. The human mind can consider any one part of a thing, as really distinct from it; as the arm, without considering the rest of the body. 2. The mind can, by abstraction, consider the mode of a substance, omitting the substance itself; or consider separately the different modes, which exist together in the same subject. This species of abstraction is used by geometers, when they consider the length of a body separately, and which they call a line, omitting the consideration of its breadth and depth; and then its length and breadth together, which they call a surface. By the same species of abstraction, we can distinguish the determination of a motion towards whatever place directed, from the motion itself. 3. By abstraction we omit the modes and relations of any particular things, in order to form an universal idea.

It is this faculty, or power of abstraction that makes the great difference between man and brutes. The latter seem to reason about particular objects

and ideas; but there does not appear in them, the least indication of abstraction.

ABSTRACTIONS, among chemists, imply the native spirits of aromatic vegetables, to distinguish them from spirits produced by fermentation.

ABSTRUSE, something deep, hidden, or far removed from the common apprehension, and methods of conceiving; in opposition to what is obvious and palpable.

The word is Latin, *abstrusus*, and compounded of *abs*, from and *trusus*, to thrust.

ABSURD, an epithet which is applied to any thing that contradicts reason, or the evidence of one's senses. It is too often made use of in religious controversies, when a point is discussed that is above human comprehension: but in such cases improperly; for though it would be absurd to affirm that four and five make only three, or that two and one are equal to nine, as clashing with a self-evident proposition; yet in religious matters, that are above the reach of human reason, it should never be applied, as the mind is too narrow to comprehend every thing that may be.

ABSURDITY, a kind of error or offence against some evident, and generally received truth or principle. The greatest of all absurdities is the contradiction. See CONTRADICTION.

ABSURDITY, in behaviour, signifies the very contrary of wit. It is next to that, of all things in the world, the most proper to excite mirth. What is foolish, is the object of pity; but absurdity, generally proceeds from an opinion of sufficiency, and consequently is an honest occasion for laughter.

ABUNDANCE, in mythology. See the article PLENTY.

ABUNDANT Numbers, with arithmeticians, are such whose aliquot parts added together is greater than the number itself, as 20, whose aliquot parts are 1, 2, 4, 5, 10, and make 22. See ALIQUOT, and NUMBER.

ABUSE, in a general sense, implies the perverting something from its true design, purpose, or intention.

The word is Latin, *abusus*, and compounded of *ab*, from and *usus*, use, q. d. contrary to the true use.

ABUSE of words, implies the using words without any clear and distinct ideas; or, sometimes, without any idea at all.

Language being the conduit, whereby men convey their discoveries, reasonings, and knowledge, from one to another; he that makes an ill use of it, though he does not corrupt the fountains of knowledge, which are in the things themselves; yet he does, as much as in him lies, to break or stop the pipes whereby it is distributed for the public use and advantage of mankind: and may

be looked upon as an enemy to truth and knowledge.

For as we are let into the knowledge of things by words, so we are oftentimes led into error or mistake by the abuse of words; flowing from these two causes, viz. the natural and unavoidable imperfection of languages, and the wilful faults and neglects of men.

In order therefore to guard against such mistakes, as well as to promote our improvement in knowledge, it is necessary to acquaint ourselves a little with the abuse of words, which men are so often guilty of.

1. They use words without clear and distinct ideas; or, which is worse, signs without any thing signified: instances of this kind may be easily had from the schoolmen and metaphysicians.

2. Inconstancy in the use of words; it being hard to find a discourse on any subject, wherein the same words are not used sometimes for one collection of ideas, and sometimes for another.

3. An affected obscurity, either by using old words in new significations, or by introducing new and ambiguous terms, without defining them, or putting them together so as to confound their ordinary meaning.

4. The taking of words for things; though this in some degree concerns all names in general, yet it more particularly affects those of substances. Thus in the Peripatetic philosophy, substantial forms, abhorrences of vacuum, &c. are taken for something real. 5. The setting them in the place of things, which they can by no means signify: thus we may observe, that in the general name of substances, whereof the nominal essences are only known to us, when we affirm or deny any thing about them; we do, very often, tacitly suppose, or intend, they should stand for the real essences of a certain sort of substances: but to suppose these names to stand for a thing, having a real essence on which the properties depend, is a plain abuse; since we would make them stand for something, which not being in our complex idea, the name we use can no ways be the sign of.

He therefore that hath names without ideas, wants meaning in his words, and speaks only empty sounds: he that hath complex ideas without names for them, wants dispatch in his expressions: he that uses words loosely and unsteadily, will either not be minded, or not understood: he that applies his names to ideas different from their common use, wants propriety, and speaks gibberish: and he that hath ideas of substances disagreeing with the real existence of things, so far wants the materials of true knowledge in his understanding, and has instead thereof chimeras.

To remedy the above-mentioned abuses of speech, the following rules may be of use:

1. A man should take care to use no word without a signification; no name without an idea which he makes it stand for.

2. Those ideas he annexes them to should be clear and distinct, which, in complex ideas, is by knowing the particular ones that make that composition.

3. He must apply his words, as near as may be, to such ideas as common use has annexed to them.

4. When common use has left the signification of a word uncertain and loose; or where it is to be used in a peculiar sense; or where the term is liable to any doubtfulness or mistake, there it ought to be defined, and its signification ascertained.

5. The last rule is, that in all discourses wherein one man pretends to instruct or convince another, he should use the same word constantly in the same sense; if this were constantly done (which no body can refuse without great dissimilarity) many of the books extant might be spared; many of the controversies in dispute would be at an end; several of those great volumes, swollen with ambiguous words, now used in one sense, and by and by in another, would shrink into a very narrow compass. *Locke on Human Understanding.*

ABUTTALS, the boundaries of a piece of land.

ABUTILON, in botany, a plant of the mallow kind, bearing a flower, that consists of five distinct petals; from the center of which arises a number of united filaments, whose tops are ornamented with round anthers, and a short single style. When the flower is decayed, the fruit appears, containing a number of cells, each of which when open discovers a kidney-shaped seed. There are several varieties of these plants, some of which produce round seed; but most of the sorts being natives of the West Indies, require more heat than this climate can naturally afford them.

ABYSS, in a general sense, signifies without a bottom: and is derived from the Greek *αβυσσος*, a bottom.

In a particular sense it means that immense cavern of the earth into which God collected all the waters on the third day, to serve as a reservoir for the supply of his creatures. Dr. Woodward conjectures, that there is a mighty mass of waters enclosed in the bowels of the earth, constituting a vast orb in the central parts of it; and over the surface of this water he imagines the terrestrial strata to be formed. This, according to him, is what Moses calls the great deep, and what most authors render the great abyss. He says, that the sea has a communication with these waters, by means of chafins in the earth: which conjecture appears not altogether groundless, as it would be difficult to account any other way for the vast influx of waters into several lakes, as well as into the Caspian sea, from which no efflux has ever yet been observed.

ABYSS, in Scripture, signifies also hell, or that immense space where, according to the opinion of the Jews, the giants are suffering the punishment of their sins: It is there that the Rephaims, or ancient giants of Canaan, are bound, with all those kings of Tyre, Babylon, and Egypt, whose pride and cruelties have been recorded in the Prophets.

These abysses are the dreary and dismal abode of the impious and unjust. "I saw," says St. John in the Revelations, "a star fall from heaven unto the earth: and to him was given the key of the *bottomless pit*: that pit, where the ungodly *shall seek death, and shall not find it; and shall desire to die, and death shall flee from them.*"

ACACIA, in botany, the Egyptian thorn. There are several sorts of this genus of plants; but all classed by Dr. Linnæus with the *Mimosa*, or sensitive plant. The principal difference between the acacia and mimosa is, that the leaves of the acacia will not fall at the touch, whereas those of the mimosa will, so as to appear withered: the sort which is best known by the name of the Egyptian thorn is very common in England, and produces a tree of a tolerable size; the leaves of which are placed opposite to each other in pairs; the flowers, which grow in bunches, consist each of one leaf, slightly divided at the extremity into five parts; the filaments are hairy and longer than the style; from the flower a pod is produced which contains several flat oblong seeds. The branches of most of the sorts are armed with strong sharp thorns. From this plant the gum arabic is taken.

ACACIA *Germanica*, an inspissated juice, made from wild sloes before they are ripe.

ACACIANS, in ecclesiastical history, the name of several sects of heretics; some of whom maintained, that the son was only of a similar, not the same substance with the father; and others, that he was not only a distinct, but also of a dissimilar substance.

ACADEMICS, a sect of ancient philosophers, the disciples of Socrates and Plato, so called from Academe, which was a garden or villa near Athens, where Plato and Socrates used to converse and dispute on philosophical subjects. The particular tenets advanced by these sages were, that all knowledge is at best uncertainty, and that truth is difficult if not impossible to be attained. They did not however carry these opinions to that extravagant pitch which the Pyrrhonians did, who doubted of every thing, but confined them to physics. It is true, indeed, that Socrates professed that he knew nothing; but it was partly through modesty that he spoke thus, and partly to ridicule the pride and vanity of his brother philosophers, who foolishly imagined there was nothing that they did not know. If we excuse in the Academics this

affectation of ignorance and diffidence of themselves, we shall find little or nothing in their doctrines but what is pure and praise-worthy. The writings of Plato are full of wisdom and truth; he taught, in the sweetest and most eloquent style, such doctrines as seem to be beyond the reach of human wisdom; which have occasioned his being upbraided with plagiarism, as if he had stolen them from the books of Moses. It must be confessed, that it is difficult any other way to account for some parts of his sublime knowledge; as that there is one infinite and eternal God, the father and creator of all things; that he made the world out of nothing, according to a certain exemplar or model in his own mind; that man was born of the earth; that he was naked; that he enjoyed a truly happy state; with several points besides, so abhorrent from the heathen, and agreeable to the Jewish philosophy, that he got the name of the Attic Moses.

Notwithstanding Plato recommended to his disciples a diffidence of themselves, and instructed them to doubt of every thing; yet he seems to have done it in such a manner as if he did not intend to leave them fluctuating between truth and error, but to put them upon their guard against rash and precipitate decisions, and teach them to accustom their minds to examine every thing freely and without prejudice, as being the only means of securing themselves from error. It were to be wished that the same could be said of those who succeeded him in his philosophy, namely Arcesilas, Carneades, Clitomachus, and Philo. But they seem to have carried his erroneous notions much higher; for they do not only affirm that we know nothing, but even that we do not know whether we know any thing.

We read of five different academies; the first under Socrates and Plato; the second under Arcesilas; the third under Carneades; the fourth under Philo, the disciple of Clitomachus; and the fifth founded by Antisthenes: but they seem rather to be branches of the same root, than so many different trees; unless indeed we except the fifth academy, in which the Stoic doctrines were dressed out in the old academic fur.

ACADEMY, a delicious garden or villa, within a mile of Athens, so called from one Academus, or Eudemus, a citizen of Athens, to whom it originally belonged. Plato tells us, that it was a kind of gymnasium, or place of exercise, in the suburbs of that city, watered by a gentle spring, and surrounded with groves of olive and plantane. It was the favourite retreat of the philosophers and sages of Athens, but particularly of Socrates and Plato; for which reason the sect founded by them was styled academic. Milton gives us a beautiful description of it in his *Paradise Regained*, Book iv, l. 244.

See there the olive grove of academic
 Plato's retirement, where the Attic bird
 Trills her thick warbled notes the summer long;
 There flow'ry hill Hymettus with the sound
 Of bees industrious murmur oft invites
 To studious musing; there Ilissus rolls
 His whispering stream. —

Cicero had a villa, or place of retirement, near
 Puzzuoli, to which he gave the name of academy,
 where he used to entertain his friends with what
 the poet calls, "The feast of reason, and the flow
 of soul." It was there that he composed his *Academical Questions*, and his book *De Natura Deorum*.
 ACADEMY, among the moderns, is generally
 used to signify a society or company of men of
 letters, established for the culture of the arts and
 sciences.

Some authors have confounded the word academy with that of university; and it is indeed sometimes used for a school, or place of instruction, where the arts and sciences are taught. We have in England two royal academies of this kind, one at Woolwich, and the other at Portsmouth, besides a great number of private schools called academies: but in the proper sense of the words they are really different; the former implying a society of learned men, who meet to confer and communicate their lights to one another, for their mutual benefit and the improvement of the arts; and the latter a body composed of graduates in the several faculties; of professors who teach in the public schools; of regents or tutors, and of students who learn under them, and aspire likewise to degrees. See the article UNIVERSITY.

Charlemagne has the honour of being the first that established an academy in Europe. It was composed of the chief wits of the court, and the emperor himself was one of the members. In their academical conferences each person was to give an account of what ancient authors he had read, and each academical assumed the name either of some ancient writer, or some celebrated person of antiquity.

At present most nations have their academies, Russia not excepted; but Italy excels in this respect, at least in point of numbers. We have but few in England; the chief of which are the royal society, the antiquarian society, the society for the encouragement of arts, and the academy of painting. See *ROYAL SOCIETY*, *ANTIQUARIAN SOCIETY*, and *SOCIETY for the Encouragement of Arts*. There is also a literary society established in Scotland. See *EDINBURGH SOCIETY*.

The French have several flourishing academies of all kinds, particularly the following:

French ACADEMY, a society instituted in the year 1635, for perfecting the French language. They meet at the Old Louvre three times a week,

during the whole year; but have no public assemblies, except those in which they receive some new academicians, and that which is held on St. Louis's day, when they distribute the prizes of eloquence and poetry, each of which consists of a gold medal. They have already published a dictionary, intitled, *La Dictionnaire de l'Academie Françoise*. Their motto is, *AP'Immortalité*.

Royal ACADEMY of Sciences was founded at Paris in the year 1666, and confirmed by the king in 1699, for the improvement of physics, mathematics, and chemistry.

The academy at first consisted of ten honorary academicians; eight strangers, associates; twenty pensioners, fellows; twenty elves, or scholars; and twelve French associates.

But in the year 1696, the academy received a new regulation; by which it was composed of ten honorary members, twenty pensioners; three geometricians, three astronomers, three mechanics, three anatomists, three botanists, three chemists, a treasurer, and a secretary, who are both perpetual; twenty associates, twelve of whom must be inhabitants of France, and eight foreigners; and twenty elves, each of whom must be attached to one of the pensioner academists.

In the year 1716, the duke of Orleans, then regent of the kingdom, thought proper to make some amendments to this regulation; and accordingly, the class of elves was suppressed, it appearing to be attended with some inconveniences, particularly that of making too great an inequality among the academicians, and being productive of some animosities among the members. At the same time he created two new classes, one consisting of twelve adjuncts, and the other of six free associates.

Ever since the establishment of this academy in the year 1699, they have been very exact in publishing every year a volume in quarto, containing either the works of its own members, or such memoirs as have been composed and read to the academy during the course of the year. To each volume is prefixed the history of the academy, or an extract of the memoirs, and, in general, of whatever has been read or said in the academy: at the end of the history are the eulogies of such academists as have died during the course of that year.

The late Mr. Rouillé de Meslay, courtfellow to the parliament of Paris, founded two prizes, one of two thousand five hundred livres, and the other of two thousand, which are distributed alternately by the academy every year; the subjects for the first must relate to physical astronomy, and those for the latter to navigation and commerce.

The motto of this academy is, *Invenit & perficit*.

Royal ACADEMY of Inscriptions and Belles Lettres,

was

was established by Lewis XIV. In the year 1663, and soon after their institution, they undertook to compile, by means of medals, a connected history of the principal events of that prince's reign.

In the year 1701, this academy received a new regulation; by which it was to consist of ten honorary members, ten pensioners, ten associates, and ten clerics; but the last have been since suppressed and united to the associates. The secretary and treasurer are both perpetual; and the academy have published several volumes, which contain, besides the memoirs which are thought proper to appear entire, extracts made by the secretary from several others, together with the eulogies of the deceased members. The academy distributes every year a gold medal of four hundred livres value, as a literary prize founded by M. Darcy de Noiville. Their motto is, *Vetat mori*.

Royal ACADEMY of Sciences and Belles Lettres of Prussia, a flourishing academy established at Berlin in the year 1700, by Frederic I. King of Prussia. This academy has published several volumes of memoirs, containing several curious and useful papers in various arts and sciences.

Imperial ACADEMY of Petersburg, a society of learned men, established at Petersburg in the year 1726, by the Czarina Catharine; since which time they have published thirteen volumes of memoirs wrote in Latin, several parts of which, especially the mathematical papers, are very valuable. The motto of this academy is, *Paulatim*.

Royal Spanish ACADEMY is an academy for cultivating the Castilian tongue, established at Madrid on the model of the French academy. The design of this society was laid by the duke d'Escalona, and approved of by the king in 1714, who declared himself its protector. It consists of twenty-four academists, including the director and secretary. Its device is a crucible on the fire, with this motto, *Limpia faja y da esplendor*.

ACADEMY of Nature Curioso, in Germany, was first founded in 1652, by Mr. Baufch, a physician, and taken, in 1670, under the protection of the emperor Leopold.

Italy alone has more academies of note than all the rest of the world; not a city but furnishes a set of learned persons for an academy, which to them seems an essential part of a regular constitution. Jarcnius has given us a specimen of their history, printed at Leipzig in 1725.

Jarcnius's account goes no farther than to the academies of Piedmont, Ferrara, and Milan; in which last city he reckons twenty-five; but adds a list of all the rest, to the number of five hundred and fifty.

ACADEMY of Painting, is a public school to which the painters resort, either to draw, or paint, and where the sculptors model after a naked person, which they call a model.

The royal academy of painting and sculpture at Paris took its rise from the disputes that happened among the master-painters and sculptors in that capital. This induced Le Brun, Sarazin, Corneille, and others of the king's painters, to form the design of a particular academy; and, having presented a petition to the king, they obtained an arret, dated the 20th of January, 1648. Their meetings were at first held in the apartments of M. Charmois, secretary to the marshal Schomberg, who drew up the first body of statutes for the academy.

Afterwards the academy conferred in the house of a friend of M. Charmois, situate near St. Eustachius's; from whence they removed to the hotel de Clisson, where they continued their exercises till the year 1653, when the academists removed into the street des Dechargeurs. In the year 1654, and towards the beginning of 1655, they obtained from cardinal Mazarine a brevet and letters patent, which were registered in parliament; and, in grateful acknowledgement for this favour, they chose the cardinal for their protector, and the chancellor for their vice-protector.

It is remarkable, that the chancellor had, from the first institution of the academy, been named its protector; but, in order to make his court to cardinal Mazarine, he declined that title, and contented himself with that of vice-protector.

In the year 1656, Sarazin granted to the academy an apartment which he at that time had in the galleries of the Louvre; but they were obliged to quit it in the year 1661: and M. de Ratabon, superintendent of the buildings, removed them to the Palais-royal, where they remained one and thirty years. At last the king gave them an apartment in the Old Louvre.

In the year 1663, the academy obtained, by means of M. Colbert, a pension of 4000 livres.

This academy consists of a protector, a vice-protector, a director, a chancellor, four rectors, adjuncts to the rectors, a treasurer, forty professors, one of which is professor of anatomy, and another of geometry; several adjuncts and counsellors, a secretary and historiographer, and two ushers.

The academy of painting holds a public assembly every day for two hours, after noon, to which the painters resort, either to design or paint, and where sculptors model after a naked person. There are twelve professors, each of whom keeps the school for a month; and there are twelve adjuncts to supply them in case of need. The professor upon duty places the naked man, who is called the model, in such a position as he thinks proper, and sets him in two different attitudes every week: this is what they call setting the model. In one week of the month he sets two models together, which is what they call setting the groupe. The paintings and models made after this

this model, as well as the copies made from them, are called academies, or academy figures. They have likewise a woman who stands for a model in the public school. Every three months, three prizes for design are distributed among the elves, or disciples, as are two others for painting, and two for sculpture, every year. Those who gain the prizes of painting and sculpture, are sent to Rome, at the king's expence, to study there, and complete themselves in their art.

Besides the royal academy, there are two other schools, or academies, of painting in Paris; one whereof is at the royal manufacture of the Gobelins: this school is under the direction of artists, to whom the king allows an apartment in the royal hotel of the Gobelins, and who generally are members of the royal academy. The other is the academy of St. Luke, which is maintained by the company of master-painters and sculptors, and was established by the provost of Paris, on the 12th of August, 1391. Charles VII. in the year 1430, granted to it several privileges, which were confirmed in the year 1584, by Henry III. and in 1613, the companies of painters and sculptors were united. This company hath at present a house near St. Denis de la Chartre, where their office is held; and a public academy carried on in the same manner as the royal academy, and where every year they distribute, among their disciples, three prizes for designs. The only academy we have in England of this kind, is in St. Martin's-lane, London.

ACADEMY of Architecture, a company of skillful architects, established at Paris in the year 1671, by M. Colbert, under the direction of the superintendent of the buildings.

ACADEMY is also used in speaking of the schools and seminaries of the Jews, where their rabbins and doctors instructed the youth of their nation in the Hebrew language, and explained to them the Talmud and the secrets of the Cabala. The Jews have always had these sort of academies ever since their return from Babylon: those of Tiberias and Babylon have been the most celebrated.

ACADEMY is also particularly understood of a riding school, or a place where young gentlemen are taught to ride the great horse, as also the use of arms, dancing, vaulting, &c. This is what Vitruvius calls ephebeum; and some others, among the ancients, gymnasium; the moderns call it equestrian, or military academy.

The duke of Newcastle will have the art of riding to have had its origin in Italy; and the first academy of this sort to have been established at Naples, by Frederic Grifon, who, he adds, was the first that wrote on this subject, which he did, like a true cavalier, and a good master. Henry VIII. says the same author, called over two Italians, disciples of Grifon, into England, who

soon stocked the nation with ecuyers, or riding-masters.

He adds, that the greatest master which Italy ever produced, was a Neapolitan, called Pignatelli; that La Broue rode under him five years, Pluvinel nine, and S. Antoine many years; and that these Frenchmen filled France with French masters, which, till then, had known only Italians.

The ground set apart in an academy for riding, is called the menage, having usually a pillar in the centre, and other pillars placed two by two at the sides.

ACADEMY Figures, in painting, are designs made after a model with a crayon or pencil.

ACAJOU, the *Cashew-Nut-Tree*, in botany, the name of a genus of trees, comprehended by Linnaeus among the anacardiums. See ANACARDIUM.

ACALEPTIC, in the ancient profody, an appellation given to such verses as have all their feet complete.

ACALYPHA, in botany, the three-seeded mercury, a plant that produces male and female flowers, neither of which have any petals: the calyx of each are composed of three roundish leaves; from the cup of the male flowers arise eight or ten stamina; in the center of the female flowers, a round ovary is situated, supporting three branching styles; when the flowers decay, the ovary is divided into three cells, containing in each one large round seed. This plant is the ricinocarpus of Boerhaave.

ACANACEOUS, in botany, are plants of the thistle kind, having heads with prickles on them.

ACANTHA, among botanists, a name given to the prickles of thorny plants.

ACANTHA, is also used by zoologists for the spines of certain fishes, as those of the echinus marinus, &c.

ACANTHA is also a term used by some anatomists, for the protuberances of the back-bone, otherwise called spina dorsii.

ACANTHABOLUS, in surgery, a kind of forceps, or instrument for pulling out thorns, and other sharp-pointed bodies, that may have penetrated the skin: also an instrument for pulling hairs from the eye-brows, &c.

ACANTHACEOUS, among botanists, an epithet given to all plants of the thistle kind, on account of the prickles with which they are beset.

ACANTHUS, in botany, the branca ursini, or bears breech; this plant produces a monopetalous unequal flower, with a double empalement, the outer composed of three leaves indented; the inner empalement consists of two leaves, the upper one concave, and serrated at the top, and the

H under

under one convex; this flower produces four stamina, two long, and two short, closely adhering to the style, which is situated on a roundish germ, that afterward becomes an oval capsule, producing two cells containing in each one fleshy smooth oblong seed.

ACANTHUS, in architecture, an ornament representing the leaves of the herb acanthus, and used in the capitals of the Corinthian and Composite orders. See the article **CAPITAL**.

For this purpose, the Greek sculptors imitated the leaves of the soft acanthus, as the Goths did those of the prickly kind.

ACARNA, a name by which Theophrastus calls the common thistle.

ACARUS, in zoology, a numerous genus of insects, comprehending the mites in general, and the lice of several animals.

ACATERY, or **ACCATRY**, an officer in the king's household, designed as a check between the clerks of the king's household and the clerks of the kitchen.

ACATHUSTUS, in ecclesiastical history, a hymn anciently sung in the Greek church, in honour of the Virgin.

ACAULIS, in botany, those flowers which have no visible stalks, but appear to rest on the ground.

ACCEDAS ad curiam, in law, a writ lying where a man hath received or fears false imprisonment in a hundred court, or court baron.

ACCELERATED, in a general sense, implied quickened, or continually increasing in motion.

ACCELERATED Motion, in physics, is that whose velocity is continually increasing; and when the velocity is equally increased in equal times, it is said to be uniformly accelerated.

The accelerated motion of falling bodies is produced by the impulse of gravity, which keeps constantly acting upon them, and thereby communicating a new increase of motion every instant.

The acceleration of the descent of heavy bodies was first discovered by Galileus; and by due application of Sir Isaac Newton's second law of motion, is clear and evident, viz. *That the change of motion is always proportionable to the force impressed, and is always according to that same line of direction.* For supposing gravity, at equal distances from the earth's center, to act uniformly on all bodies, and that the time in which any body falls to the earth be divided into infinitely small and equal parts: let gravity incline the body towards the earth's center, while it moves in the first infinitely small part of the time of its descent; if after this the action of gravity should cease, the body would go towards the earth's center equally, with a velocity equal to the force of that first impression. But then, if we suppose that the action of gravity does

continue, in the second instant the body will receive a new impulse towards the earth, equal to that which it received in the first instant, consequently its velocity will be doubled, in the third instant trebled, in the fourth quadrupled, and so on: for the impulse made in any preceeding instant is no ways altered by that which is made in the following; wherefore the instants of time being supposed infinitely small, and all equal, the velocity acquired by the falling body will be in every instant as the times from the beginning of the descent, and consequently the velocity will be proportionable to the time in which it is acquired.—After the same manner it may be proved that the motion of ascending projectives shall be equally retarded; for since the force of gravity acts continually and equally against the motion first begun, it must diminish or abate the motion according to the time of ascent, till at last it entirely cease.

The space run through by a moving body during a given time, and with a given velocity, may be considered as a rectangle compounded of the time and velocity.—Let the right line AB (Plate II. fig. 1.) express the time of any heavy body's descent, and let BC, at right angles to it, denote the velocity acquired at the end of the fall. Draw AC, and divide AB into any number of equal parts, denominated intervals or proportions of the given time, as DE and FG, which will express the velocities acquired in the times of descent AD and AF; for because of the similar triangles AB:AF::BC:FG, and as AF:AD::FG:DE; wherefore it is evident that the velocities are as the times of descent; that is, as the lines or elements of the triangle ABC, drawn parallel to the base BC.

By imagining shorter divisions of time, for example, but half so long as the former, the indentures of the figure will be proportionably more contracted, and it will approach near unto a triangle: And if they be taken infinitely small; that is, if increments of the velocity be supposed to be acquired continually, and at each indivisible particle of time, which is really the case, the rectangles so successively produced will form a true triangle, as ABE; (See Plate II. fig. 2.) the whole time AB consisting of minute portions of times, A 1, A 2, &c. and the area of the triangle ABE, of all the minute surfaces, or minute trapeziums, which answer to the divisions of the times; the area of the whole triangle expressing the space run through during the time AB. Or the triangles ABE, A 1 f being similar, their areas are to each other, as the squares of their homologous sides AB, A 1, &c. and consequently the spaces gone through, are to each other as the squares of the times.

Whence also may be deduced this great law of acceleration: *That a body descending with an uniformly accelerated motion, describes in the whole time of*

its descent, a space which is exactly the half of that which it would describe uniformly in the same time, with the velocity it acquires at the end of its fall. For, as we have already shewn, the whole space which the falling body has run through in the time AB, will be represented by the triangle ABE; and the space that body would run through uniformly in the same time, with the velocity BE, will be represented by the rectangle ABEF: But it is well known, that the triangle is exactly equal to half the rectangle: so that the space run through, will be the half of that which the body would describe uniformly in the same time, with the velocity acquired at the end of its fall.

We may therefore conclude, 1st, That the space which would be uniformly described in half the time AB, with the ultimately acquired velocity BE, is equal to that which has been actually run through by the falling body during the whole time AB.

2d. If the falling body describes any given space, or length, in a given time; in twice that time, it will describe four times as much; in thrice that time, nine times as much, &c. In a word, if the times are in proportion to each other, as the series 1, 2, 3, 4, &c. the spaces run through will be as the squares of these numbers, that is, as 1, 4, 9, 16, &c. that is to say, if a body describes, for example, 16 feet in the first second minute of its fall, in the two first taken together, it will describe four times 16 feet; nine times 16 feet in the three first seconds taken together; and so on.

3d. The spaces described by falling bodies, in a series of equal instants or intervals of time, will be as the odd numbers 1, 3, 5, 7, 9, &c. that is, the body which has run thro' 16 feet in the first second, will in the next second run thro' 48 feet, in the third second 80 feet, &c. and since the velocities acquired in falling are as the times, the spaces will be likewise as the squares of the velocities; and the times and the velocities in the sub-duplicate ratio of the spaces.

The motion of an ascending body, or of one that is impelled upwards, is diminished or retarded by the same principle of gravity acting in a contrary direction, after the same manner that a falling body is accelerated. See RETARDATION.

A body projected upwards, ascends until it has lost all its motion; which it does in the same interval of time that the same body would have taken up in acquiring by falling, a velocity equal to that with which the falling body began to be projected upwards. And consequently the heights to which bodies projected upwards, with different velocities, arrive, are to each other as the square of those velocities.

ACCELERATED Motion of Projectiles. See PROJECTILES.

ACCELERATED Motion of compressed bodies. See COMPRESSION and ELASTICITY.

ACCELERATION, in physics, an increase of velocity in the motion of a body; it is opposed to retardation, by which term is understood a diminution of velocity. See MOTION, VELOCITY, and RETARDATION.

ACCELERATION, in mechanics, implies the augmentation or increase of motion in accelerated bodies. See *ACCELERATED Motion*.

ACCELERATION of the Motion of Pendulums. See the article PENDULUM.

ACCELERATION, among the old astronomers, implied the difference between the revolution of the primum mobile and that of the sun, and which they computed to be about three minutes and fifty-six seconds.

ACCELERATIVE Quantity of centripetal Force, in physics, is the measure of that force, proportional to the velocity which it generates in a given time. See CENTRIPETAL FORCE.

ACCELERATOR, in anatomy, the name of two muscles of the penis, so denominated from their accelerating the discharge of the urine and semen.

ACCIDENTENTES, or **ACCENSORES**, in the Roman church, are a lower class of ministers, whose principal business consists in lighting, snuffing, and trimming the lamps, candles, and tapers.

ACCENSI, in the Roman armies, were a sort of supernumerary soldiers, intended to supply the places of those who might be killed or disabled.

ACCENT, in a general sense, signifies a certain tone or manner of speaking, peculiar to some country or province.

ACCENT is used in grammar for the particular affection or impression of the voice on certain words and syllables, by which they acquire their due force and meaning. Some who have written upon this subject make a distinction between accent and tone, referring the former to the variation of the time in speaking, and the latter to the different modulations or inflexions of the voice. But there seems to be no occasion for such a distinction: we shall therefore consider them as one and the same thing, in treating of this article.

The ear is soon fatiated with a continuation of one and the same sound; nor can the soul be affected at all by the same motions and percussions of the air. Nature therefore has wisely instructed the voice, in every language, not to move by single and uniform sounds, nor to strike perpetually the same notes, without any variation of the time. No:—by such a pronunciation as this, every sound must necessarily be furd and unmeaning, painful to the voice, and ungrateful to the ear. Repeat only the following line in the same tenor, unchanged alike in time or accent, through every syllable, and you will have no idea yourself, nor be understood by any one else:

Was | glād—thāt | nōw | hīs | scā | ā | shōre
should | find.

But if you unite every two of these sounds into one movement, and let your voice alternately rest on one, and slip over another, and rise on one, and fall on the other, you will find a meaning, and speak and be heard with pleasure. This resting and varying of the voice is what we properly call the accent; and this it is which gives to every language its peculiar strength, sweetness, and harmony. It is very justly remarked by Cicero, that “*mira est natura vocis, cujus quidem, e tribus omnino sonis inflexo acuto gravi, tanta sit, et tam suavis varietas perfecta in cantibus. Est autem in dicendo etiam quidam cantus.*” *The nature of the voice is admirable, which from three modulations only, the circumflex, the grave, and the acute, affords so great and pleasing a variety of singing: nay there is a kind of chant even in our common discourse.* Every language has its peculiar accent, which differs according to the genius and temper of the people by whom it is spoken: it is either grave or acute, strong or weak, rare or frequent. This it is which regulates the music of different countries, giving to each that particular character which makes it strictly its own: for as these are the sounds by which nature teaches us to express the various emotions of the soul, no music can possibly affect or captivate us that is not in some measure directed by them. And this perhaps is the true reason why an English audience is justly displeased with the greatest part of the recitative that is performed on our theatres. It does not bear any resemblance to our common manner of expressing ourselves; but is generally borrowed from the Italians, and seems indeed to be nothing else than the accent of that language carried a little beyond its natural pitch.

It has long been a matter of much contention amongst the learned, whether the Greeks originally made use of accents, or they are of modern invention: We would here be supposed to mean those three characters that are placed over the syllables of their words, to denote the accent. These are, first, *The acute accent*, when the voice is to be raised, which is figured thus (´); secondly, *The grave accent*, when the voice is to be depressed, expressed thus (`); and thirdly, *The circumflex*, composed of the *acute* and *grave*, which is marked thus (ˆ). It is certain that in speaking they must have made use of accents, as otherwise their language would have been furd and unmeaning: but it is very improbable, that they expressed their accents by particular marks; as we find that all ancient inscriptions and manuscripts can boast of very little precision, being written in capital letters, equidistant from each other, without the least distinction either of words or phrases. If they did not take the pains then to

express even their words exactly, so that they could not be mistaken; how unlikely is it, that they should mark, with such prodigious accuracy, the manner in which every word was to be spoken? Indeed such a labour as this appears to be unnecessary; as there are very few words in a living language of so doubtful a signification, as to require that the pronunciation of them should be expressly marked down, lest they be misunderstood by the ignorant and unwary. How then shall we account for the introduction of these particular marks and characters? Shall we agree with Isaac Vossius, and other eminent grammarians, that they are of modern invention? but at what precise time were they first of all made use of? Some are of opinion, that they are not of much later date than about 900 years, and were introduced by the Arabs to prevent a barbarous pronunciation, which was then breaking in upon them: but it appears to us as if they were of much longer continuance; being in all likelihood invented, when Athens was the seat of arts and science, when she was in her meridian glory, the envy and admiration of the world. At that happy period, when the youth of all nations, but particularly of Rome, resorted to her for instruction; when she sent forth her orators, her poets, her painters, and musicians to every corner of the globe; these accents might then first of all be made use of to facilitate the knowledge of her language to strangers, and ascertain a pure and perfect pronunciation of it in foreign countries. But however this might be, certain it is, that they were never intended for those ridiculous purposes, to which they have been wrested by gothic and tasteless grammarians. They were undoubtedly meant for nothing, but to mark some certain inflexions and modulations of the voice: what these were, it is impossible at this length of time to determine; but one may be bold enough to affirm, that they could never be intended to affect the time or quantity of any word, for that would destroy all order and harmony, and throw the whole language into confusion.

ACCENT is also made use of, but improperly, to express the characters by which the quantity of any word is determined; such is the *long accent*, which shews that the voice is to dwell upon that syllable, and is marked thus (—).

The *short accent*, which shews that the time of pronunciation ought to be quick, and is marked thus (˘).

There are persons, who rank the hyphen, the diaetole, and apostrophe, amongst accents.

ACCENT is also applied to any particular tone, or brogue, that is contracted by any person, from the country or province where he has been bred: thus we say the northern accent, the Welch accent, &c.

ACCENT is used too in poetry to signify the cadence or césura, but in this sense it is improperly applied. In music it means the modulation of the voice, to express any particular passion. Every bar or measure is divided into *accented* and *unaccented* parts. The accented parts are the principal, being those intended chiefly to move and affect: it is on these the spirit of the music depends. The harmony must always be full and free from discords in the accented parts; in the others it is not so absolutely necessary, as they are frequently passed over unobserved.

ACCENTOR, in music, implies one of the three singers in parts, or the person who sings the highest part in a trio.

ACCEPTANCE, in the common law, signifies the tacitly agreeing to some act before done by another, and which might have been defeated before acceptance.

Thus, if a bishop before the statute of 1 Elizabeth, leased part of his bishopric for a term of years, at a certain rent, and dies before the term is expired; the new bishop, if he accepts and receives the rent when due, the lease is confirmed, which otherwise the new bishop might have set aside. In like manner, if baron and feme, seized of land in right of the feme, join and make a lease or feoffment, at a certain reserved rent, and the baron dies before the lease be expired; the feme, if she receives or accepts the rent, she confirms the lease or feoffment, and this acceptance shall bar her from bringing a *cui in vita*.

ACCEPTANCE, among civilians, implies the consenting to receive something offered, which had we refused could not have taken effect.

ACCEPTANCE, among merchants, denotes the signing or subscribing a bill of exchange, by which the acceptor obliges himself to pay the contents of the bill, even though the drawer should fail before it becomes due. See *BILL of Exchange*.

ACCEPTATION is used in grammar, to signify the particular sense in which a word is taken or received: thus we say, Such a word in its first and natural acceptation denotes, &c. It is owing to the different acceptation in which words are taken, that so many disputes arise, and are carried on in the world.

ACCEPTILATION, among civilians, signifies an acquittance given by a creditor to a debtor, without receiving any money.

ACCEPTOR, or **ACCEPTER**, among merchants, the person who accepts a bill of exchange.

ACCESS, in a general sense, denotes the approach of one towards another.

ACCESS, in a more limited sense, implies a permission or leave to come near any person, place, or thing.

ACCESS, among physicians, is used for the be-

ginning of a paroxysm, or fit of some periodical disease.

ACCESSARY, or **ACCESSORY**, in law, signifies a person who was any ways aiding or assisting in a felonious action.

Accessaries are of two kinds, before and after the fact.

An accessary before the fact, is a person, who, though absent at the time the felony was committed, yet had previously procured, counselled, or commanded the principal to commit it.

An accessary after the fact, is a person, who knowing the felony to be committed by another, receives, relieves, comforts, and assists the felon.

In cases of high treason, there can be no accessaries, either before or after; for all consenters, knowing receivers, or comforters of traitors, are principals.

In cases that are criminal but not capital, there can be no accessaries, for all the accessaries before the fact, are in the same degree as principals; and accessaries after, cannot be in law under any penalties as accessaries, unless the acts of parliament that inflict those penalties, do also expressly extend to receivers or comforters, which some do.

It follows therefore, the term accessary refers only to felonies, whether by the common law, or by act of parliament.

ACCESSIBLE, something that may be approached.

ACCESSIBLE Altitude. See **ALTITUDE**.

ACCESSION, among civilians, is used to imply the property acquired in such things as are connected with, or appendages of other things.

ACCESSION, among physicians, signifies the same with what is generally called paroxysm. See **PAROXYSM**.

ACCESSION, among politicians, is used to signify a prince's agreeing to, and becoming a party in a treaty already concluded between other potentates; and also to denote a prince's coming to the throne, on the death of the preceding king.

ACCESSION, in the Roman church, implies a peculiar method of electing the pope; and consists in one of the candidates having obtained two thirds of the votes; for when this happens, the rest are enrolled by acceffion.

ACCIDENT, in a general sense, implies something that is unusual, or that happens by chance.

ACCIDENT, a term in grammar, which is made use of to signify a property that is really attached to a word, though it is not in the definition essential to it. Besides the accidents that are peculiar to nouns substantives, such as the case, gender, declension, and number, there are four others that are attendant on words. The first is, when a word is used in a figurative sense, or differently from what it was originally meant to signify. Thus for instance, the primitive meaning of the word bear, was that of a rough, shaggy, savage animal: from

which it is adopted to describe a person of a rude, awkward, and brutal behaviour.

The second is, when words are derivative, as godly, heavenly, earthly, &c. which come from the primitive words God, heaven, earth.

The third accident is, when from two or more simple words, a complex is formed: thus, for instance, from the simple words *common* and *wealth*, comes the compound term *common-wealth*; which does not convey the meaning of the two words of which it is made up, but acquires a sense of its own, and signifies state or kingdom.

The fourth is the accent or tone of voice with which words are pronounced, which frequently determines their meaning, nay, sometimes gives them a sense quite foreign to their original signification; as when they are spoken with passion, or ironically, &c.

ACCIDENT, in logic, is when we join a confused and undetermined idea of substance with a distinct idea of some mode; because that idea is capable of representing all things to which that mode can belong; as the idea of round comprehends all round bodies in general.

This idea, expressed by the adjective *round*, forms the fifth universal, and is called accident, because not essential to the thing to which it is attributed. It should, however, be here observed, that when we consider two substances together, we may consider one of them as the mode of the other: thus a dressed man may be considered as a whole, composed of the man and of his clothes: but the dress, with respect to the man, is only a mode under which we consider him, though his habit may be substances.

The Aristotelians, after distributing beings into ten classes, reduced them to two general ones, viz. substance and accident. From the latter they formed nine others; quantity, relation, quality, action, passion, time, place, situation, habitude.

ACCIDENT, in the healing art, implies a revolution, occasioned by a disease, or some new cause, which adds strength to a distemper already existing. Thus the sudden suppression of the saliva in a peripneumony, is a dreadful accident.

The most celebrated practitioners in physic, recommend a particular regard to the violence of accidents; because their continuance may augment the distemper in such manner, as to render it incurable.

ACCIDENTAL, in a general sense, is an epithet given to such things as happen by accident.

ACCIDENTAL *Point*, in perspective, is that point in the horizontal line, where all lines parallel among themselves meet the perspective plane.

ACCIPITER, in ornithology, the name of a whole race of birds, the distinguishing characteristic of which is, that they have a hooked, or crooked beak.

This order comprehends three genera, viz. the parrot, the owl, and the hawk kind.

ACCISMUS, in antiquity, denotes a feigned refusal of what one earnestly desires.

The accismus was a piece of political dissimulation, for which Augustus and Tiberius are famed.

ACCISMUS, in rhetoric, is accounted a species of irony. See IRONY.

ACCLAMATION, ACCLAMATIO, in Roman antiquity, a shout raised by the people, to testify their applause, or approbation of their princes, generals, &c.

ACCLAMATION, in rhetoric, the same with what is otherwise called epiphonema. See EPIPHONEMA.

ACCLAMATION *Medals*, among antiquaries, those whereon the people are represented as expressing their joy by acclamation.

ACCLIVITY, a term used to denote the ascent of a hill, or rising ground, as declivity is the descent.

ACCLIVITY is sometimes used by writers in fortification, for the talus of the rampart. See TATUS.

ACCOLADE, in antient customs, the ceremony of conferring knighthood, by the king's laying his arms about the young knight's neck, and embracing him.

ACCOLLE, in heraldry, a term used in different senses; sometimes it denotes the same with accolade; sometimes two things joined together; at other times, animals with collars or crowns about their necks; and finally, battons, or swords, placed saltierwise behind the shield.

ACCOMMODATION, among divines, is the applying what is said of one person or thing to another: thus the words of Isaiah, directed to the Jews of his time, are by St. Paul accommodated to the Jews who were cotemporaries with that apostle.

ACCOMMODATION is also used for an amicable agreement between two or more contending parties.

ACCOMPANIMENT, in music, is used for the instruments which accompany a voice, to make the music more full.

Among the moderns, the accompaniment frequently plays a different part or melody from the song it accompanies; but authors are not agreed whether it was so among the ancients.

ACCOMPANIMENT, in heraldry, denotes any thing added to a shield by way of ornament, as the belt, mantling, supporters, &c.

ACCOMPANIMENT is also used for several bearings about a principal one, as a saltier, bend, fess, &c.

ACCOMPLICE, in law, a person who is privy to, or aiding in the perpetration of some crime. See ACCESSARY.

By the law of Scotland accomplices cannot be prosecuted till the principal offenders are first convicted.

ACCOMPLISHMENT, in a general sense, denotes the perfecting, or entirely finishing and completing any matter or thing.

ACCOMPLISHMENT is more particularly used for the fulfilling of a prophecy; in which sense we read of a literal accomplishment, a mystical accomplishment, &c. See the article **PROPHECY**.

ACCOMPLISHMENT is still more particularly used for the acquirement of some branch of learning, useful art, polite exercise, &c.

ACCOMPT and **ACCOMPTANT**. See **ACCOUNT** and **ACCOUNTANT**.

ACCORD, in music, the same with what is more usually called concord. See **CONCORD**.

ACCORD, in law, a verbal agreement between two or more, where any one is injured by a trespass, or other offence committed, to make satisfaction to the injured party; who, after the accord is performed, will be barred in law from bringing any new action against the aggressor for the same trespass. It is safest, however, in pleading, to allege satisfaction, and not accord alone; because in this last case, a precise execution in every part thereof must be alleged; whereas in the former, the defendant needs only say, that he paid the plaintiff such a sum in full satisfaction of the accord, which he received.

ACCOUNT, or **ACCOMPT**, in a general sense, is used for all arithmetical computations, whether of time, weight, measure, money, &c.

ACCOUNT is also used collectively, for the books in which merchants, traders, and bankers enter all their business, traffic, and bargains with each other.

The method of keeping these is called book-keeping. See **BOOK-KEEPING**.

To *open an ACCOUNT*, is to enter in the ledger the name, the surname, and the place of abode of the person with whom you have dealings; after which the several articles are posted or placed, either on the credit or debit side, according as the person is become your creditor or debtor.

To *place or post a sum to ACCOUNT*, is to enter it in the ledger, either on the debit or credit side, according as the persons are become debtors or creditors.

To *examine an ACCOUNT*, is to read it exactly, in order to prove the truth of the computation, or detect errors, if there are any.

To *settle an ACCOUNT*, is to sum up all the articles, both on the debit and credit side, and find the balance between them; which being placed on the least side, makes the sum of both equal: this is otherwise called shutting, balancing, closing, or making up an account.

ACCOUNT in Company, an account kept by traders in partnership, wherein all articles relating to their joint trade are entered.

ACCOUNT is also used in different senses, as for profit, hazard, &c. Thus we say a man has found his account in something, or it has turned to good account; also, if a man commits errors, they shall be on his own account, &c.

ACCOUNT, in law, is a writ or action which lies against a person, who, by reason of his office or business, is obliged to render an account to another, but refuses to do it; as a bailiff, for instance, to his lord.

ACCOUNT, in the remembrancer's office in the exchequer, is the state of any branch of the king's revenue; as the account of the mint, of the wardrobe, of the army, of the navy, &c.

Chamber of ACCOUNTS, in the French polity, a sovereign court, answering nearly to our exchequer. See **EXCHEQUER**.

ACCOUNT of Sales, among merchants, an account of the disposal and net proceeds of certain merchandizes, after deducting charges and commission.

Auditing an ACCOUNT, the examining and passing it by an officer appointed on purpose.

ACCOUNTANT, or **ACCOMPTANT**, in a general sense, denotes one whose business it is to keep accounts.

ACCOUNTANT-General, in the court of chancery, a new officer appointed by act of parliament, to receive all monies lodged in court, and convey the same to the bank of England, for better security. The salary of this officer and his clerks is to be paid out of the interest made of part of the money, it not being allowable to take fees in this office.

ACCOUNTREMENT, an old term, signifying dress, still used for the furniture of a soldier.

ACCRETION, in natural history, the increase or growth of a body by an external addition of new parts: thus it is, salts, shells, stones, &c. are formed.

ACCRETION, among civilians, a term used for the property acquired in a vague or not occupied thing, by its adhering to or following another thing already occupied; thus, if a legacy be left to two persons, and one of them die before the testator, the legacy devolves to the survivor by right of accretion. Alluvion is another instance of accretion. See **ALLUVION**.

ACCROCHE, in heraldry, denotes a thing's being hooked into another.

ACCUMULATION, in a general sense, the act of heaping or amassing things together.

ACCUMULATION, among lawyers, denotes the concurrence of several titles to the same thing, or of several circumstances or proofs to make out one fact.

ACCUSATION, among civilians, the bringing a criminal action against any person; in which sense it differs only in circumstances from what
among

among us is called impeachment. See IMPEACHMENT.

ACCUSATIVE, in grammar, is the fourth case of nouns, in those languages that have declensions, that is, whose words have different terminations assigned them, according to the different relations in which they stand with respect to the verb. Varro says, "Sunt destinati casus, ut qui de altero diceret distinguere posset quum vocaret, quum daret, quum accusaret; sic alia quadam discrimina quæ nos et Græcos ad declinandum duxerunt." *The cases of nouns were invented, that he who should speak of another might distinguish when he would call, when he would give, when he would accuse; so there are other distinctions too, which induced us and the Greeks to decline our nouns.*

The termination of the accusative case serves to discover the word which marks the term, or the object of the action, which the verb signifies. All verbs that express actions which pass from the agents, as I despise, I conquer, &c. must have subjects to receive those actions: for if I despise, I must despise something; so that such a verb evidently requires after it a noun or name, to be the object of the action expressed. In English we have nothing to denote the accusative case, but the place in which the noun stands, as I hate *hyperisiss*, the accusative naturally following, and the nominative preceding the verb. Where there is any transposition of the words, as frequently happens in poetry, the sense must determine which is the accusative case, and which not, as in the following lines:

"And oh! you mortal engines, whose rude throats
"Th'immortal Jove's dread clamours counterfeit!"

which in prose would run thus: "Oh you mortal engines, whose rude throats counterfeit the dread clamours of immortal Jove!"

ACEPHALI, or **ACEPHALITÆ**, a name given by ecclesiastical historians to several sects who were destitute of any head or leader. They also extended it to such bishops as were exempted from the discipline and jurisdiction of their patriarch.

The word is Greek, and compounded of *a* priv, *κεφαλα*, a head.

ACER, in botany, the maple-tree. See the article MAPLE-TREE.

ACETABULUM, in antiquity, a certain measure equal to one eighth of our pint.

ACETABULUM, in anatomy, implies a large cavity in a bone, formed for receiving the convex head of another bone, in order to admit of a circular motion in the joint formed by this articulation.

ACETABULUM also signifies a kind of glandular substance, generally called cotyledon, many of which are found in the placenta of some animals. See **COTYLEDON**.

ACETOSA, sorrel, in botany. See **SORREL**.

ACETUM, vinegar. See **VINEGAR**.

ACHATES, the agate, in natural history. See **AGATE**.

ACHILLEA, in botany, is a name given to the ptarmica and millefolium of Tournefort. The common sort, known by the name of yarrow, is a plant that grows wild in most parts of England; the flowers make an agreeable appearance, but blow not so well in gardens as in uncultivated places: there are other sorts that are classed under the general name, which are most of them natives of foreign countries.

ACHILLEID, or **ACHILLEIS**, a poem of Statius, in which the author proposed to recount the whole life and exploits of Achilles; but being prevented by death, he hath only treated of the infancy and education of his hero.

Notwithstanding the opinion of Scaliger, who prefers Statius to all the heroic poets, Greek and Roman, not excepting even Homer himself, every impartial judge must allow that he is deficient in imagination, as well as judgment; and that his language, thro' a constant affectation of grandeur and sublimity, is for the most part stiff, unnatural, and bombast. As to the work itself, he has certainly made choice of a very improper subject for an epic poem, as it would not allow of that unity of action which is absolutely essential to compositions of this nature. Accordingly the Achilleid is not so much an epic poem, as a history in verse.

ACHILLES, an appellation sometimes given to the principal argument made use of by each sect of ancient philosophers, in defence of their system.

Tendo **ACHILLES**, in anatomy, is a large tendon formed by the union of the tendons of the four extensor muscles of the foot. It has its name from the fatal wound which Achilles received before the walls of Troy, in that part.

ACHOR, in medicine, a small ulcer in the skin of the head, perforated with a great many little holes, which contain a viscid humour resembling ichor. It is the third species of a tinea, or scald-head. See the article **TINEA**.

ACHRONICAL, in astronomy. See **ACRONICAL**.

ACID, any thing which affects the tongue with a sense of sharpness and sourness.

The word is formed from the Latin *acidum*, which is derived from the Greek *ακν*, a point or edge.

The chemists call all substances acids, which make an effervescence with an alkali. However, this does not seem to be a true characteristic of acids, because some acids will cause an effervescence, upon being mixed with acids of a different kind; and alkaline substances will do the same with alkalies; and acids with bodies which are neither alkaline nor acid, but neutral.

Another

Another mark of acids is, that they change the colour of the juices of heliotropium, roses, and violets, red; whereas animal alkalies turn them green. We mention animal alkalies, because others will not always produce that effect.

The celebrated Boerhaave has made a great number of experiments to prove that oil is the pabulum or food of fire, and an acid seems essential to the composition of oil. That vegetable oils contain an acid is, in some, manifest to the taste, and we can obtain it from others by distillation. This acid is the cause why oils so readily mix with alkaline salts, and why they are, by this juncture, neutralized, and converted into soap. Hence we have another very obvious characteristic, which will more justly discover acids in bodies, than either their causing an effervescence with alkalies, or producing a red colour when mixed with the juice of heliotropium, roses, or violets, viz. that all bodies whatever which will flame, contain either a manifest or a latent acid; for acids are, probably, the only bodies in nature that are convertible into that species of fire which we call flame. Vegetables flame so long as their black oil contains an acid both by its smell and effects.

Mineral oils in general contain a manifest acid, as the oil of coal, petrolæum, naphtha, and all kinds of bitumens.

In animal oil the acid is not so manifest, but seems wrapt up in a large portion of volatile alkaline salts. But we may conclude, that an acid enters its composition; first, because after it is cleared from the membranous cells which contain it, and the blood-vessels which enter it, though kept ever so long, it does not putrify like the other parts of animals, nor does it afford a nidus for the eggs of insects, and breed maggots: but if it has once been deprived of a part of its alkaline salts by boiling, it will keep for ages unaltered and untainted in the hottest seasons, of which tallow candles may serve as an obvious instance. Now acids are the great preservatives against putrefaction, and known destroyers of those kinds of insects that breed in animal bodies.

Secondly, because animal oils not only preserve themselves, but also all other animal and vegetable substances immersed in them from putrefaction.

Thirdly, because, like vegetable oils, they readily mix with alkaline salts, which they neutralize, as is evident in making some kinds of soap.

Pure acids are not easily inflammable by the common methods, because of their solidity and strong cohesion; but when they are divided into exceeding fine particles, dispersed in the interstices of other bodies, and by means of some other subject set on fire, they burst into a lucid flame, and explode with the utmost violence.

Acids seem to be of the greatest use in the

economy of the world, because they are so universal. In the bowels of the earth we meet with them in almost every mine and mineral; but principally in those prodigious rocks of salt which are found in almost every country, and which the industry of a great many ages have not been able to exhaust. Such are those in the famous salt mines in Poland, and our own in Cheshire, where vast quantities are got every year, and exported. Not to mention the quantities of acids hourly discharged from the bowels of the earth, in the salt which may be found, by a nice examination, in the waters of every spring, the freshest not excepted.

In the air the acid is universal; and that in every part of it.

It is remarkable that the acid abounds more in the air, when the winds blow from the east and north, and when the weather is serene. This the learned Hoffman informs us, is confirmed by the observations of those who are concerned in nitre-works, who remark, that, during these winds, their alkaline earth is impregnated with an acid.

Physicians have observed, that the south winds favour pestilential constitutions of the air, especially if the season happens at the same time to be moist and rainy; and that the malignancy is abated by winds which blow from the north and north-east: so that there is reason to believe that the alkaline contagion is destroyed by the aerial acid.

The acids of vegetables, says the accurate Boerhaave, are either native, or produced by the help of fermentation. Native vegetable acids seem to owe their origin entirely to the juices which the plants draw from the earth that nourishes them; and hence all these may perhaps be looked upon as belonging originally to the fossil kingdom, especially as plants which grow in the sea, and have not their roots inserted in the earth, consist purely of calcareous parts, and, in distillation, yield an oily, volatile acid.

In some vegetables the native acids discover themselves evidently; as in sorrel, the trifolium acetosum, and the juice of all fruits, especially while unripe; for when concocted by the heat of the sun, they grow more mild. The sap likewise of all vegetables, which rises in the spring, is almost as acid as vinegar. Many woods also and aromatics contain a true acid, though not so manifest. Who could have expected to have found an acid in guaiacum, sassafras, cinnamon, and a great many more of the same kind, if distillation had not demonstrated it? But fermentation seems more and more to exalt the latent acid of vegetables; for the juices of vegetables which are exceeding ripe and sweet appear to have scarcely any thing acid in them, as we see evidently in the expressed juice of grapes. Who can perceive any thing like acid in cassia, manna, honey, and sugar? and yet, when these are properly fermented, the acid

presently appears, especially when the wine begins to grow finer, and more subtle. Is there the least indication of an acid in ripe mealy corn? and yet even this, after a little fermentation, discovers an acidity. As these acids are something different, and of a more subtle nature than native ones, they are generally called vinous acids. They are of two sorts; for they are either dispersed through the wine, in form of liquid acids, or else gradually collect themselves together in the wine, and fix themselves to the surface of the vessel, in the solid form of tartar.

But the acids of vegetables produced by a second fermentation are generally called acetose: for if any known wines are, by an admixture of austere, acid, crude juices, made to undergo again a proper acetose fermentation, they will be converted into vinegars, will consume their own tartar, become much more acid, and acquire a stronger and more durable sourness, which will remain even in distillation: hence there may be obtained from vinegars, by distillation, a pure active acid of the utmost service in chemistry.

It will also be necessary to take notice here of what are called fermenting acids; by which we mean vegetable juices in the very act of fermentation, and consequently in a kind of middle state between that which is natural to them, and that which they obtain when the fermentation is completed; for, during this interval, the most elastic part of the fermenting liquid acquires such a power as is hardly to be equalled by any thing in nature: for if this savage, incoercible, explosive, acid spirit, rising from a vast quantity of fermenting vegetables, should pass through a very small vent-hole into the nostrils of the strongest man, it would strike him dead in an instant. If it does not act with all its force, it causes a sudden apoplexy; if less powerful still, a loss of the senses, with a paraplegia; if very lightly, only a vertigo. The truth of this has been too certainly proved by many melancholy instances.

There are also discovered other very singular acids, that are, in some measure, of a balsamic and oily nature; we mean such as are drawn from vegetables by fire in a close vessel. Thus the wood of guaiacum, juniper, oak, and a great many others, if reduced to dry shavings, and carefully distilled in a retort, will yield a limpid reddish liquor, which is very acid, somewhat oily, and has a good deal of the smell of a herring dried in the smoke. This liquid may be rendered stronger by depuration and rectification; and then the solvent virtue of this menstruum will appear to be very singular.

Fossile native acids are rarely to be met with; for it is now discovered, that the medicinal waters, once considered as an acid, approach, in every character, nearer to an alkali. There is often indeed a vapour observed in mines, which re-

sembles a suffocating, sulphureous acid, and by other marks demonstrates its acidity; but it is very seldom found alone unmixed, and in a fluid form.

But whenever it happens, which is very often the case, that it meets with a solid body, capable of attracting that acid, it unites with it, and becomes fixed and palpable; and when it is afterwards drawn out of that fixed body, it then falls under the cognizance of our senses; and then, as far as it is possible for us to judge, appears to be always one and the same.

For if it lays hold of a pinguious fossile, it produces various kinds of sulphurs, which, when burnt, emit fumes, which being collected, refrigerated, and mixed with the humid air, yield the spirit or oil of sulphur per campanum. If you pour this acid liquor into a clean glass vessel, and expose it for a considerable time to a heat equal to that of boiling water, you will distil from it a considerable quantity of pure water, which, whilst the sulphur was burning, had insinuated itself out of the air into the acid fumes of the sulphur; and there will then remain at the bottom a ponderous, thick, caustic acid, which, in every character, resembles the purest oil of vitriol, except in its having no particles of a volatile metal, which are always found more or less in oil of vitriol.

But if this acid happens to corrode lime-stones, it then produces alums, which are different according to the diversity of the matter which is mixed with them. All these, if they are at first lightly calcined, and then with an intense fire urged into vapours, will, by a condensation of these, yield a liquor, which, when purified according to art, is nearly the same with the former procured from burning sulphur.

Again, if native green vitriol be reduced, by the help of a moderate fire, to a dry white powder, and then exposed to a fire gradually increased to the most extreme degree, it will emit white cloudy vapours, which, collected into a liquid, and accurately depurated, is again the very same as was before obtained from sulphur and alum.

The blue vitriol likewise treated in the same manner, yields a liquid, which is the same with the former; nor can it be distinguished from them, if rectified according to art.

Another fossile acid which we are acquainted with, is produced from nitre only, so that there never was perhaps a single drop seen of it in the world but what was distilled from nitre. For if nitre be intimately mixed with three times its quantity of bole, clay, brick-dust, or any thing of the like nature, and then urged with a very strong fire, a great part of it will be converted into red fumes, which, being condensed into a liquid, is called spirit of nitre. Or if dry nitre be mixed with an equal quantity of oil of vitriol, and distilled in the strongest sand-heat, gradually increased, the same spirit

of nitre will be procured from the same red fumes.

Or, lastly, nitre rubbed with an equal quantity of the red calx of vitriol, or alum, and then urged with a very great degree of heat, will emit the same fumes, and from them yield a spirit of nitre, which is as good and as pure as the former; but it is then called by the chemists aqua fortis, aqua stygia, and aqua docimastica.

Sea-salt, like nitre, when it is pure, discovers no signs of acidity; but if it be treated in the manner just mentioned with regard to nitre, it is changed into a volatile acid liquor. For if, to prevent its melting, it is mixed with three times its weight of earth, and then urged by a fire gradually increased to the greatest degree, it will be dissipated into dense white fumes, which float about, and are very volatile, but being collected, form a liquor of a green or green colour.

If distilled with oil of vitriol, it yields the same liquor, but more volatile: and if mixed with the fæces of distilled alum, or vitriol, and afterwards exposed to a very strong fire, it will then give the same spirit of sea-salt: and these spirits, prepared according to these three different ways, are entirely one and the same; and they will also be the same, whether they be made from sal gemmæ, fountain, or sea-salt. This spirit has this peculiarity, that if it be drawn from the purest salt, and you repeat the distillation upon fresh pure salt, when it begins, through the violence of the fire, to grow exceeding hot, it emits white fumes, and dissolves gold, which no other acid in nature is able to penetrate.

ACIDS, in the materia medica, denote such medicines as are possessed of an acid quality; such are vinegar, spirit of vitriol, &c.

These being powerful antiseptics, are esteemed good in all putrid and malignant diseases, and by their cooling virtue are no less efficacious in inflammatory and feverish cases. However, great care ought to be taken not to administer them in such large quantities as to corrode the bowels, or coagulate the blood.

Acids are also commended in the plague, and as ftyptics. Thus, vinegar not only serves to stop hæmorrhages, but being sprinkled upon a red-hot tile or iron, corrects the putrefaction of the air. See *PLAGUE*, &c.

ACIDITY, *Aciditas*, that quality in bodies which renders them acid. See *ACID*.

ACIDULÆ, a diminutive of acids, sour, cold mineral waters, which contain a brisk spirit, in contra-distinction to *Thermæ*, or those which are hot.

The name owes its original to a supposition that these waters were acid; which later observations and experiments have proved to be without foundation.

The admirable virtues and extraordinary effi-

cacy of mineral waters, both hot and cold, in perfectly curing the most obstinate and inveterate diseases, are so well known and attested by long use, and an infinite number of experiments, as to put the matter beyond all manner of dispute. But whence these waters derive their sanative power and virtue, is a thing not so commonly known; and indeed there are very few who know how to discover, by a chemical examination, the elements and ingredients in which their wonderful efficacy consists.

Now there is no better way to discover the elements of medicated waters, than by evaporating the liquid by a very gentle heat, either in a tin vessel set over hot embers in the open air, or, which is better, in a glass cucurbit, carefully saving the liquid which drops from the alembic, that the proportion of the solid to the liquid may be obtained. If the evaporation be continued to a dryness, and the mass left in the cucurbit be accurately weighed, we shall have the weight of the ingredients, which are of a more fixed nature, and, though of a different texture, must be examined.

First then, a solution of the residuum must be made in pure distilled water, which is always requisite for the more accurate examination of things chemically prepared; for many spring waters contain a considerable quantity of earth and salt. In this solution the salt is separated, and the earth remains, being less soluble in water. It is easy to know whether this salt be alkaline, by mixing it with an acid, for then it forms a neutral salt; or with sal ammoniac, in which case a strong urinous smell will be produced; or it may be known by adding to it a solution of mercury sublimated in water, for it will then precipitate a yellow powder; or if you mix it with syrup of violets, it will turn of a green colour.

The case is a little more difficult, when the salts left after evaporation are not of one and the same, but of different kinds; as when, for example, alkaline salts are mixed with those which are neutral. In this case, pour common water on the dry mass, and, after a gentle agitation, decant it off. By this means there will remain a saline powder not easily dissoluble, for alkaline salts readily dissolve in water. There is another way of separating neutral salts from alkaline, and that is by crystallization; in which, rightly performed, every neutral salt being best adapted to receive a solid figure, descends first in the form of crystals, and nothing but a lixivious liquor remains, which swims on top, and receives with more difficulty a solid form.

The next thing is to determine the genuine nature and properties of these neutral salts. In order to this, it must be observed, that no other salts are conveyed out of the bowels of the earth in the vehicle of water, than either common salt,

or a kind of neutral salt, of a vitriolic and sulphureous nature, being compounded of the acid of sulphur, or vitriol, and a sort of alkaline earth; the former, that is, common salt, may easily be distinguished, partly by the taste and cubical figure which it assumes by crystallization, and partly by emitting, when mixed with oil of vitriol, a copious white fume of a very penetrating smell. The other salt, which owes its origin to an universal, subterraneous, sulphureous acid, is thus tried: mix two parts of this salt with one part of salt of tartar, and one part of powder of charcoal; let them incorporate and fuse together in a crucible, in a melting heat; there will then be produced a red mass, of a sulphureous alkaline taste, resembling the liver of sulphur, and from which, by highly rectified spirit of wine, a yellow tincture of sulphur may be extracted, which will tinge silver of a sooty colour.

From a solution of this mass in water, by an acid liquor, is precipitated the true lac sulphuris; a manifest proof that the mineral sulphur, which is compounded of the universal acid and inflammatory principle, is revived in this process. This is not only true with regard to all salts procured by art, but also by means of this process, a sulphureous alkaline mass may be produced out of all the salts, common alone excepted, which are found in mineral waters, both hot and cold; with this difference, that if the neutral salt be compounded of an alkaline salt and the spirit of sulphur, the fusion by fire will be performed the more easily; but if this acid be united with a terrene, or gypseo-calcareous salt, it becomes far more difficult.

Besides alkaline and neutral salts, there is, in many cold mineral waters, a vitriolic salt, which is seldom of a fixed nature, but, for the most part, subtil and volatile. This salt is discovered, in all waters, by the dark purple and blackish colour which immediately follows from their being mixed with fine powder of galls, or the rhind of pomegranates. The volatility of the spirit of this vitriol, or rather of the acid of this mineral, which, in conjunction with martial or olearius particles, constitutes the subtil salt of vitriol, is manifest from those mineral waters, which produce a black tincture on being mixed with powder of galls; for if they are exposed for some time to the open air in a warm place, they lose entirely their vitriolic taste and faculty of changing their colour.

There remains yet something to be examined in mineral waters, and that is their subtil spirituous particles, which seem to be of an zeroo-ethereal nature, and to be endowed with an elastic property. That they contain a great quantity of these is evident, both from the vapour which strikes the nostrils, and also from their affecting the head in drinking. To these particles must also be ascribed

the vast quantities of bubbles which are generated in some cold mineral waters, on their being poured out of one glass into another.

But these bubbles are generated in still greater plenty, and with more force and celerity, when they are mixed with equal quantities of Moselle, or Rhenish wine, or any other that contains a subtil acid and a little sugar; for then they look well to the eye, and become of a delicious taste, the vapours proceeding from them in such plenty, that they seem to smook. This effervescence which generates these bubbles, proceeds from the conflict of the alkaline salt, which prevails in mineral waters, with the subtil acid of the wine.

This spirituous principle, which resides in these waters, is also the cause why vessels or bottles close stopped, when heated, burst with great violence; a certain proof of the expansive power of this subtil matter.

Moreover, the existence of this spirituous principle, which ennobs mineral waters, may be proved by the help of an air-pump; for on exhausting the receiver, so great a quantity of bubbles will rise to the surface, that it will appear like a fluid heated to a degree of ebullition.

Such things, therefore, as have undergone an examination, and do not produce the like effects and phenomena, may be looked upon as much inferior in virtue: for it is that subtil mineral spirit which endues the waters and their ingredients with such extraordinary qualities, so as not only to enter immediately, and penetrate the very inmost recesses and emunctories of the body, but also communicate greater strength and elasticity to the solids. Hence the passage of the waters through our bodies is facilitated, the vessels freed from all obstructions, and the secretion of useless matter in an extraordinary manner promoted.

But as there is no spring water which does not afford some quantity of an earthy substance, which, after evaporation, is hardly soluble, so we find the same in mineral waters, whether hot or cold, even in those of the greatest reputation for medicinal virtues. Now the nature and properties of this gross substance ought also to be enquired into; for as the waters in their course meet with various kinds of earth, some particles thereof are easily taken up by the intestine motion of these waters.

These particles are chiefly either chalky, okreous, clayey, or stoney. If the water be impregnated with particles of a chalky nature, it will produce an effervescence with an acid; or if the residuum after evaporation be calcined, it will acquire the highest degree of acrimony. If the waters, especially those which are hot, contain a large quantity of this chalky earth, it will separate in cold weather, and stick to the vessels which contain it, and in a little time cover them with a stoney crust.

If the sediment which remains after crystallization and evaporation, be of a yellowish colour, and in calcining changes into a red, it is a sign that the water is impregnated with martial particles, which never fail of producing salutary effects on the human body, by their gentle astringent and corroborating virtue.

But this okerous substance, though it derive its colour from iron, cannot be dissolved by an acid, because it is of the nature of clay.—Many waters abound with this solar and martial earth, without other saline and spirituous ingredient; whence they are of no small service in chronic distempers, both drank and used as baths.

Besides the hot and cold-mineral waters in which alkalies predominate, there are other medicinal springs impregnated neither with acid nor alkali, nor capable of tinging syrup of violets, but containing only a salt of a neutral or middle nature, which may best be procured by evaporation.

ACIDULATED, among physicians, an appellation given to such medicines as have been mixed with some acid. See **ACID**.

ACINARIA, in botany, a name sometimes given to the marsh-whortle-berries. See **WHORTLE**.

ACINI, among botanists. See **ACINUS**.

ACINIFORMIS Tunica, in anatomy, the same with **uvea**. See **UVEA**.

ACINUS, in botany, a name given to grapes or berries growing in clusters, in opposition to *baccæ*, or such berries as grow single.

ACKNOWLEDGMENT, in a general sense, is the owning or confessing some thing; but more particularly denotes the reward of some service, or the grateful requital of a favour received.

ACKNOWLEDGMENT-Money, a certain sum paid by tenants in several parts of England, on the death of their landlords, as an acknowledgment of their new lords.

ACLIDES, in Roman antiquity, a kind of missive weapon, with a thong fixed to it, whereby it might be drawn back again.

Most authors describe the aclides as a sort of dart or javelin; but Scaliger makes it roundish or globular, with a wooden stem to poise it by.

ACME, in a general sense, denotes the height, point, or top of any thing. Among physicians it is used for the highest pitch to which a distemper rises.

ACME also denotes the prime or best part of a thing.

ACNUA, amongst the ancient Romans, signified a certain determinate measure of land, equal to the English rood, or fourth part of an acre. See **ROOD**.

ACOEMETÆ, or **ACOEMETI**, a set of monks, who chaunted the divine service night and day in their monasteries, without intermission; from which they were styled *ακοιμηται*, or men who lived without sleep. We must not suppose however that

they did in fact watch *always*, and pray *without ceasing*: human nature could not support such incessant fatigue. They divided their body into three different choirs, who regularly succeeded and relieved each other, so that there was no interruption in the sacred service.

It is generally believed that Alexander, a monk of Syria, was the founder of this sect, about the beginning of the fifth century. He first preached at Constantinople; but being obliged to quit that city, he built a monastery near the mouth of the Pontus Euxinus, where he died in the year 430. He was succeeded by John, and Marcellus, who having built the famous monastery near Constantinople, has been mistaken for the institutor of this order. Some years afterwards one Studius, a nobleman of consular dignity at Rome, erected a monastery at Constantinople, which contained a thousand persons, and was highly celebrated for its piety and learning. He dedicated it to St. John, and called it from his own name Studium; whence the monks who lived in it gained the appellation of Studites.

This sect was long famous for their exemplary piety; but in time they degenerated, and were at length condemned by the emperor Justinian, and pope John II. for favouring the heresy of the Nestorians.

There are a kind of Acoemetæ still subsisting in the Romish church; the religious of the holy sacrament coming properly enough under that appellation, as they have adopted, from the Latin church, what was called the *laus perennis*, praying before the holy sacrament, some or other of them, day and night.

ACOLUTHI, in antiquity, was a name given of old to the Stoics, who were remarkably tenacious of their principles, and were not to be shaken from their resolutions.

The word is of Greek extraction, compounded of *α priv.* and *καλεω*, way; as never deviating from the original course. In this sense it has been applied to those persons who were firm and unmoveable in their opinions, be they what they would.

ACOLUTHI, in ecclesiastical history, is the name of the first four minor orders below the subdeacon.

The word is Greek, being derived from *ακολουθος*, that is, a servant. It was a very ancient order in the Latin church, being mentioned by Cyprian, but was unknown to the Greek. Their function in the church was to light the candles, and to bottle the wine that was for consecration, as is remarked in the fourth council of Carthage, and in the ancient rituals; whence we learn, that when they were ordained, the archdeacon presented them with a candle and a bottle, to signify to them the office they were to supply in the church. We find in the Martyrology, that they held sometimes the

covered chalice at mafs, which is now done by the fubdeacon. They affifted too the bishops and officiating priefts, in helping them to the facerdotal habits.

There were in the Roman church three forts of acoluthi: the palatini, who waited upon the pope; the ftationarii, who affifted in the churches; and the regionarii, who helped the deacons in the functions which they exercifed in different parts of the city.

ACONITE, in botany, a genus of plants commonly known by the name of wolfsbane and monkhood.

The petals of the flower confift of five unequal irregular leaves, formed fo as to bear a great refemblance of a helmet, or hood, which in fome fpecies is very confpicious; and from this particular the name of monkhood is taken. The common forts are too well known to require any farther description.

All the fpecies of aconite are extremely acrimonious, and thence too often occasion fatal convulfions, or inflammations, that terminate in a mortification.

ACONTIAS, in zoology, a fpecies of ferpent, otherwife called jaculum, or the dart-fnake, from its vibrating its body in the manner of a dart. It is about nine or ten inches long, and of the thicknefs of a man's little finger. On the back it is of a milky grey colour, variegated with fmall black fots, and furrounded with a white circle, like fo many eyes.

The neck is wholly black: and from it there run two milk-white ftreaks along the back to the tail. The belly is perfectly white. It is found in Egypt, and in the iflands of the Mediterranean.

ACONTIAS is alfo ufed by naturalifts for a kind of comet, or rather meteor, with a roundifh or oblong head, and a long flender tail refembling a javelin, from whence it takes its name.

ACORES, in geography. See **AZORES**.

ACORN, the fruit of the oak. See the article **OAK**.

Acorns are faid to have been the primitive food of mankind. They are astringent, and therefore efteemed good in fluxes. However, they are principally ufed at prefent, for fattening of hogs, poultry, &c.

ACORUS, in the materia medica, a name given to two very different roots, the galangal, and the calamus aromaticus. See **GALANGAL**, and **CALAMUS AROMATICUS**.

ACORUS adulterinus, or *Baffard ACORUS*, a name given by fome botanifts to the root of the yellow water-iris, or flag-flower.

ACUSTICS, in mechanics, is the art of affifting the fenfe of hearing, by instruments contrived for that purpofe, as hearing-trumpets, whifpering-galleries, &c. for the conftruction of which, fee thofe articles.

It is poffible, by the help of an extended wire, to hear the beat of a watch more than a furlong, and that almoft instantaneous; and Dr. Hook, in the preface to his Micrography, fays, that he knew of a way by which it is eafy to hear a perfon fpeak through a wall three feet thick.

The word is Greek, *ακουικα*, and derived from *ακουω*, to hear.

ACOUSTIC Duct, in anatomy, a name fometimes given to the external paffage of the ear, generally called meatus auditorius. See **MEATUS AUDITORIUS**.

Acoustic Instruments, are instruments contrived to affift the hearing.

ACQUEST, or **ACQUIST**, in law, implies goods acquired by purchafe or donation, in contradiftinction to thofe defcended by inheritance.

ACQUISITION, in a general fenfe, implies the obtaining or procuring fomething. But the lawyers ufe it to fignify the right or title to the enjoyment and property of an eftate procured by purchafe.

ACQUITAL, in law, fignifies the freeing a perfon from the fufpicion of guilt; or the declaring a perfon innocent of the crime he is accufed of.

ACQUITTANCE, a difcharge in writing for a fum of money, witneffing that the perfon to whom it is given hath paid the fame.

ACRE, in furveying, is an Englifh fuperficial meafure of land, containing ten fquare chains, of twenty-two yards each.

The French acre is equal to one and a quarter of the Englifh, while that of Strafburg is only about half of the latter.

ACRID, an appellation given to fuch things as are of a fharp or pungent tafte. Dr. Grew fays, an acrid tafte is compounded of pungency and heat.

ACRIMONY, that quality in things which renders them acrid. See **ACRID**.

ACROATIC was a denomination given by Aristotle to fuch lectures as were calculated only for his particular friends and difciples, being chiefly employed in demonftrating fome fpeculative or abftrufe part of philofophy.

The word is Greek, and derived from *ακροαομαι*, to hear.

ACROMATIC, or **ACHROMATIC**, in optics, is a term applied to a particular fpecies of telescope, the moft perfect of the refracting kind, and for the invention of which the late Mr. John Dollond obtained his majesty's letters patent for the fole difpofal thereof. But though it be certain that Mr. Dollond was the firft perfon who made any thing of this kind public, yet it is not quite fo clear that he was the firft who thought of it, or even put it in practice; as appears by a paper, written by the late Mr. James Ayscough, and given as a diffection to Mr. Eaftland, one of his workmen, and which

which is to the following effect: "A lens of crown-glass, flat on one side, and convex on the other, of two feet focus; and one of flint-glass, flat on one side, and concave on the other, sufficient, when combined with the former, to make the focal distance three feet." This paper is dated 1752, which is a considerable time before Mr. Dollond made any thing of this kind public. The result is not known; but the reader may compare it with the following theory, which is agreeable to the patentee's construction.

Every ray of light, although it consists of an infinite number of component rays of different colours, is white during the time it is passing through the medium in which it is first generated; but in passing obliquely from that into a denser, it will change its direction toward the perpendicular, and at the same time be separated into its component rays, which from that time proceed on diverging from each other, like rays from a center, each of which will then appear of its own particular colour; as is evident in the phenomenon of the rainbow. This bending of the ray, called its refraction, is caused by a particular property in light called its refrangibility; and the divergency is caused by the different degrees of refrangibility in its component rays; and the more the original or compound ray is refracted, the greater will be the divergency of its component rays, when it is refracted by one given medium. See DIVERGENCY, LIGHT, RAY, REFRACTION, and REFRAINGIBILITY.

Now from this property of light it has been concluded, that any two different mediums that can be made to produce equal degrees of refraction, will also produce equal divergencies; whence it should likewise follow, that equal and contrary refractions would not only destroy each other, but that the divergency in one would also be exactly counterbalanced by the other, and that to produce refraction without divergency is impossible. But those conclusions are not true; for it appears from numberless experiments, that a ray of light, after equal and contrary refractions, may be still subject to divergency, if refracted through different mediums; and also that different refractions may be produced, and yet the divergency in one exactly corrected in the other: as for example, if a prism (see PRISM) of white flint-glass, ABC, (see Plate III. fig. 1.) be taken, whose angle C is about 25°, and another CBD, of crown-glass, whose angle B is 29°, be joined to it, so as to refract in contrary directions, it will be found that a beam of light, SP, incident on the former at P, will, after it has been refracted through both prisms, pass on in a direction nearly the same as it did before it was refracted by the first; but at the same time, the divergency of its component rays will be very considerable, and any object on which it may fall will appear strongly coloured. Again, if the prism of white flint-glass

be retained, and one of crown-glass, whose angle of refraction is to that of the white flint one nearly as 3 : 2, be added to it, it will then be found, that the divergency caused by the refraction in one, will be exactly counteracted by that of the other, but that there will still remain a considerable angle of refraction.

Now to determine the lens of a given focus, which shall produce the same effect with the given prism ABC or BCB, (see Fig. 1.) with CD = the given focal distance as a radius describe the semi-circle ABG, (Plate III. fig. 2.) and make the $\angle ACB = \frac{1}{2}$ the refracting angle in the given prism, and draw BC; also draw BI perpendicular to DC, and BA and BE tangents to the equal and similar arcs BD and BF. Now, since the angle ABC is a right angle $\therefore$ the triangles ABI, EBI, and ACB, are similar, and the $\angle ABI$, EBI, and ACB equal, whence the prism ABE is similar to the given prism, and BI, the semi-aperture of the lens required.

For if we suppose a ray of light SB parallel to the axis of the lens AC, and incident on it at the extreme part B, it is evident that it will be refracted to the same point in the axis, viz. C, the center of the sphere, both in the prism and lens, since they there perfectly coincide; and it is well known from experiment, that parallel rays are refracted to the same point in the axis, let them fall on what part of the spherical surface they will. See APERTURE, FOCUS, LENS, and PRISM.

COR. Hence it is very evident (notwithstanding what may have been said to the contrary) that when DC is constant, the semi-aperture BI and arc BD (or BF) are so too; and consequently that the aberration arising from the spherical surface of the lens cannot be remedied without departing from the theory.

ACROMION, in anatomy, signifies the upper or superior part of the scapula, or shoulder-blade. See SCAPULA.

The word is formed from the Greek *ακρος*, the highest, and *ωμος*, the shoulder.

ACRONYCAL, in astronomy, is applied to the rising of a star above the horizon, or some other point of the heavens, at sun-setting; or its sinking below the horizon when the sun rises; in which case, the star, &c. is said to rise or set acronyca.

The word is Greek, *ακρονυχος*, and compounded of *ακρος*, extremity, and *νυξ*, the night.

The acronyca is one of the three poetical risings and settings of the stars; the other two are called *cosmical* and *heliacal*. See COSMICAL and HELICAL.

ACROSPIRE, the popular term for what the botanists call the germ, plume, or plumule. See PLUMULE.

ACROSPIRED, in the art of making malt, implies that the grains of barley are shot or sprouted out at both ends. See MALT-MAKING.

ACROS-

ACROSTIC, the name of a kind of poetical composition, disposed in such a manner, that the initial letters of the verses make up some person's name, title, motto, &c.

The word is compounded of the Greek *ακρος*, extreme, and *εξος*, verse.

ACROTHERIA, in architecture, are little pedestals, usually without bases, anciently placed at the middle and two extremes of the pediments; and serving also to support statues, &c. The word is also sometimes used to signify the figures which are placed as ornaments on the tops of churches; and those sharp pinnacles that stand in ranges about flat buildings, with rails and balusters.

ACT, *Actus*, in a general sense, implies the exertion or effectual application of some power or faculty.

It is distinguished from power, as the effect from the cause, or as the thing produced from that which produces it.

ACT, among logicians, denotes an operation of the human mind, as judging, willing, abstracting, &c.

ACT, among lawyers, is used to signify an instrument or deed in writing, serving to prove the truth of some bargain or transaction.

ACT is also used for the final resolution or decree of an assembly, senate, council, &c.

ACT of Faith, *Acto da fé*, in the church of Rome, is the utmost exertion of priestly tyranny, being no other than a gaol-delivery, for burning, &c. the unhappy prisoners who have unfortunately fallen into the unrelenting and despotic power of the judges of the inquisition.

ACT, in dramatic poetry, is a certain part or division of a play, contrived to give a respite to the actors and the audience. Every just dramatic action should consist, according to Horace, of five distinct parts, dependent on each other. These different portions of the poem are called acts, because they may be considered as so many subordinate actions, which tend to the ultimate point in view. When they all run in one direct line, and succeed each other naturally, till they arrive at the proposed end, then the action is simple, and without episode. It is otherwise, when there are collateral branches which are not united to the principal action till towards the end of the play; for in that case the plot is complex, and these are episodes. If they never join the common stream at all, but are entirely superfluous, they are faulty, and have a bad effect; as they call off the attention of the spectators from the main design, and divide and weaken the distress. Such, for instance, are the love-scenes in the Tragedy of Cato, which may be lopt off entirely, without doing the least damage to the main action of the poem.

The five acts have each their particular rules, which are necessary to be observed by every one

who intends to form himself after the model of the ancients.

The first, which is called the *Protafis*, because it contains the proposition of the subject, ought to explain the action of the drama in a plain and clear manner; it should bring us acquainted with all the personages, and their characters; and should lay a foundation for the denouement and unravelling the plot. I shall instance from the Tragedy of Oedipus by Sophocles, after just premising that the Greeks did not divide their plays by acts, but by choruses, or interludes, which answer exactly the same purpose. At the opening of the play, the people request the king to find some remedy for the evils they groan under. He tells them, he has sent Creon to consult the gods, and is every instant in expectation of his return. Creon enters with an apparent air of satisfaction, and informs them of the oracle's commands to punish the murderers of Laius: the king makes a resolution to leave nothing undone towards the discovery of those murderers.

We have here a clear exposition of the subject: first, the distress of Thebes; secondly, the cause of her misfortunes; and thirdly, the remedy is proposed, by which the evil is to be vanquished.

The second and third act should be taken up in heightening the plot, and keeping the expectation and inquietude of the audience continually increasing. This was called by the Greeks the *Epitasis*. Thus in the Oedipus, act the second and third, the king pronounces before-hand the edict against the murderer of Laius, and then exhorts his people to yield him all assistance in detecting the criminal, and bringing him to punishment. Just at that time arrives Tiresias the prophet, whom the king questions about the murderer, but he refuses to answer. This throws Oedipus into a rage: at last Tiresias discovers to the king every thing that concerns him: Oedipus believes that it is a plot of Creon's, who was jealous of seeing a stranger, as he was, upon the throne, and wanted to succeed him: however, what Tiresias said created the king no small uneasiness. Creon endeavours to justify himself, but the king is enraged: Jocasta comes in, and in order to make Oedipus quite easy, tells him not to credit Tiresias, for the oracle had foretold that Laius should be killed by his own son, and that son had died soon after he was born: the acquaints him moreover, that Laius had been murdered by thieves, in a place where three great roads met. These last words, dropt without design, increase his uneasiness; he asks fresh questions; he enquires into circumstances, which serve to prove to him too clearly, that he is himself the author of the murder committed in that place. One thing remains to be solved, which is, the report that several were concerned in the murder of Laius, whereas Oedipus was alone when he did it: an of-
ficer

ACT

ficer of the household, who was well acquainted with the circumstances, is sent for: in the mean while Oedipus relates to Jocasta, that while he was at the court of Polybus, king of Corinth, he had one day been reproached with not being the son of that prince; and not having been able to get this point cleared up by the king, he consulted the oracle at Delphos, which, instead of giving him a satisfactory answer, had told him that he should kill his father, and marry his mother. In order to prevent this, he had resolved never to see Corinth more, and in his way to Thebes, had met with such a man as Laius was described, and killed him and some of his retinue; that when this happened, he was alone by himself; therefore, if Laius had been killed by a number of people in company, he certainly could not be the person that murdered him. Here we see all is in agitation and perplexity; the dreadful oracle begins in some measure to be accomplished against him; and we wait in trembling anxiety for the event.

The next rule is the *Catastasis*, which carries on the intrigue, and heightens the distress that is raised in the *Epitasis*, till at last the plot, being ripe for unravelling, leads to the *Catastrophe*. Thus the fourth act begins with Jocasta in great disorder preparing for a sacrifice. A messenger arrives from Corinth, with an account of the death of Polybus. Jocasta is partly appeased, as she thinks the oracle has now proved false, at least in one particular: she sends to acquaint Oedipus with the pleasing news. He no longer dreads being the murderer of his father, but is still in apprehension of becoming the incestuous partner of his mother's bed. The Corinthian, in hopes of silencing his fears, informs him that the queen of Corinth was not his mother, nor Polybus his father; and then relates to him the manner of his having received him an infant from the hands of a shepherd on mount Citheron. Oedipus perceives that this shepherd is the very same person he sent for. Jocasta, who is acquainted with all the remaining parts of the story, is for preventing the king from enquiring further: he is determined to know the whole: the queen, unable to stand the fatal discovery, departs. The officer who was sent for arrives, and a most dreadful scene ensues: every thing is discovered, by confronting the two shepherds. Oedipus finds himself guilty of all the horrid crimes which the oracle foretold; and nothing remains but to see the punishment inflicted on him. This leads directly to

The last rule of the drama, called by the Greeks the *Catastrophe*, which unravels the intrigue, and brings the play to a conclusion. Accordingly the fifth act opens with an officer, who relates what has passed in the palace: the queen has killed herself, and Oedipus, not having arms to take away his life, has dug out his eyes with one of the clasps

ACT

of Jocasta's robe, and is filling the palace with the most bitter lamentations: Creon enters and upbraids him, but at length he is permitted to take a last farewell of his children: after this he is conducted back to the palace, and so the piece ends.

From this analysis of the Tragedy of Oedipus, we may collect the use of the choruses or interludes, which, as was hinted above, answer the same purposes with the more modern divisions of the drama, called acts. These were invented by the Romans, to give a breathing-time to the actors and spectators: but we must not suppose that during the intervals between the acts, when the theatre remains empty, the plot stands still: No; though there is no action visible to the spectators, it is supposed all the while there is one passing out of sight; so that it is not merely for the sake of the respite that these acts are observed, but to give affairs a greater degree of probability, and render the plot more interesting. For the spectator who sees the action prepared that is to pass in the interval, does not remain idle, but supplies in his imagination the part of the absent actors: by which means he is agreeably surprised to see a new act come upon the stage, which is the result or natural consequence, if I may so say, of what has been passing in his own mind.

It should be the business of an author, to contrive that the most dry and difficult parts of the drama should be transacted between the acts: just as the ancients endeavoured to throw the narrative and unentertaining parts of their plays into the choruses.

Horace has determined the number of acts to be five: but such a rule seems to be drawn rather from custom, than the reason of the thing. An author should be governed entirely by the subject that he chuses: and if this is of such a kind, that it cannot be drawn out into five acts without embarrassing it with episodes, or loading it with incidents foreign to the business; he had better confine it within three or four acts, than suffer a slavish observance of rule to get the better of nature and propriety.

The acts are divided into scenes, and Vossius remarks that among the ancients, an act never contained more than seven scenes: it is easy to perceive that they should not be too numerous, as a proportion should be kept up between the length of each act; but there can be no rule as to the exact number, which seems to be arbitrary.

ACTS of the *Apostles*, one of the sacred books of the New Testament, which was placed among the canonical books at the council of Laodicea, and has been acknowledged such by every church without controversy. It contains the history of the infant church during the space of 29 or 30 years; that is, from the ascension of our blessed

ACT

Saviour Jesus Christ, till about the 63d year of the Christian æra.

It is generally supposed to have been written by St. Luke, from its being addressed to Theophilus, and making mention of his Gospel, in which he had set forth the actions and doctrines of Christ till his ascension. He here resumes the thread of his history, and gives us an account of the ministry of the apostles and growth of the church. This book contains the accomplishment of many promises made by our Saviour; his resurrection and ascension; the descent of the Holy Ghost on the apostles, and the wonderful change it wrought on their hearts and manners; their preaching, and the miracles they performed in confirmation of it; their zeal and prudence in the government of the church at Jerusalem; the concord, disinterestedness, and charity of the first Christians; in short, every thing that happened in the church till the apostles separated themselves, to sow the seed of salvation throughout the whole world. From that period St. Luke dropt the history of the other apostles, from whom he was removed, and attached himself to that of St. Paul, who had chosen him for the companion of his labours and travels. Him he followed, the chosen vessel of the church, in all his missions, and even to Rome itself: for it appears, that the Acts of the Apostles were published the second year of St. Paul's residence in that city, that is, in the sixty-third year of Christ, and the 9th or 10th of the emperor Nero. The title of this work, which was composed in Greek, is more pure than that of the other canonical books; and one may remark that St. Luke was better skilled in the Greek than the Hebrew language, as his quotations of the Old Testament are always taken from the Septuagint version.

Several different works have been published under the title of the Acts of the Apostles, of which the first was the acts of Paul and Thecla, written by a disciple of St. John, for which he was degraded. Afterwards the Manicheans forged a work, called the Acts of St. Peter and St. Paul, which were full of their errors. They make the apostles say, that the souls of men and beasts are the same, and work miracles to make dogs and sheep talk: other writings of this kind are, the Acts of St. Andrew and St. John, the Voyage of St. Peter, the Translation of St. Paul, with several more too tedious to mention.

ACTIAN Games, ludi Actiaci, in antiquity, were games instituted by Augustus, in commemoration of the victory he gained over Marc Antony at Actium.

Some will have it that they were celebrated every third year; but Strabo, whose authority is now generally followed, tells us, that they returned every fifth year only, and that they were sacred to Apollo, thence called Actius.

ACT

ACTIAN Years, a series of years commencing from the battle of Actium. See EPOCHÆ.

ACTION, *actio*, in a general sense, implies nearly the same with act. See ACT.

ACTION, as applied to epic poetry, is that which makes the subject or the matter of the poem: in the dramatic, we call it more properly plot or fable. See DRAMA, PLOT, FABLE.

The five following qualifications seem essential to the epic action: it should be *single*, *great*, *marvellous*, *probable*, and *affecting*, or *interesting*.

First, It should be single: for if two actions were to be carried on at once, both of them equally interesting, the heart would be divided, and all its emotions would be vague and uncertain; if they were not equally interesting, that which was the least so, would be tiresome and palling; from which it follows, that unity is essential to the epic action. Hence we may collect that the life of a hero, which comprizes a vast variety of actions, can never be the proper matter of a regular poem: and that for several reasons; first, because it is too diffused to be taken in at one view; secondly, because all the parts of it are not equally heroic; and thirdly, because they do not necessarily depend on each other, nor tend to one common end.

But it may be asked, what it is that makes the action of a poem single. Is it the unity of the hero? Certainly not; for the Iliad comprizes a whole people. Is it the superior excellence of any one particular hero? That cannot be; for if Achilles excelled in valour, Ulysses excelled no less in prudence, Nestor in wisdom, and Agamemnon in authority. How shall we then define it? The action is single when it is independent of every other action, and when all its parts are connected in a natural manner with each other. This unity of action is known from the very proposition of the subject itself: thus Virgil says, I sing the hero who, after a thousand toils, settled at length in Italy. Here it is plain that the action of Æneas is the conquest of Italy, and the establishment of his people in a foreign land. If he had said, I sing the despair of Dido; though in that case his poem would have contained but one single book, it would still have been a compleat work: or if he had said, I sing the descent of Æneas into hell, the funeral obsequies of old Anchises, or the fatal adventure of Nisus and Euryalus; in each of these cases the action of his poem would have been entire, though consisting at most of but five or six hundred verses. But saying as he did, I sing the hero who settled in Italy; every obstacle this hero had to surmount; before he was established in his kingdom, became part of the poet's subject; and every adventure he met with, that had any connection with the main action, might be introduced

ACT

duced as episodes, to refresh the mind of the reader by an agreeable variety. See *EPISODE*.

The next point to be considered is the greatness of the epic action: a common and ordinary adventure does not furnish from its own stock either matter sufficiently interesting, or such a fund of useful instruction, as we ought to meet with in an epic poem. Nothing less than a hero, who is the favourite of the gods; or the reduction of a famous city; or the conquest of a kingdom; or the common fate of mankind, is worth the consideration of the epic muse. The life of an ordinary person, or a trivial story, or a love intrigue, may furnish matter for a history, a novel, or a romance; but an epic poem, which strains every nerve of the human genius, should attempt nothing but what is big with grandeur and magnificence.

But it is not enough that the action of an epic poem be great, it should also be marvellous. Petronius says, *Per ambages Decorumque ministeria, fabulofumque sententiarum tormentum præcipitandus est liber spiritus*. "Through all the intricate mazes of fate, conducted by the ministering gods, the wild unfettered genius of the poet must dart, and bring his machinery from the vast unbounded space of fiction." It is the business of an epic poem to raise our admiration and astonishment. If we look into Homer, the great father of this species of poetry, we are all at once wrapt in amazement: Jupiter thunders on mount Ida; we see gods and goddesses mingle in a croud of mortal combatants, covered with dust and heavenly ichor. How warmly are they interested! what surprising revolutions do they occasion, attacking and overcoming each other! Virgil trod in the steps of this mighty master: nothing is transacted in the *Æneid*, without the interposition of some deity: the gods are every where! Juno traverses the air; the monarch of the winds lets loose the bellowing tempest; all is uproar and confusion, until Neptune the god of ocean rises, and drives back the winds to their caverns. It seems from the frequent use which is made of these divine agents, that an epic poem could not exist without machinery of this nature, which gives to the most trifling and common incident of life an air of the marvellous. I would not here be supposed to mean, that an epic poem could not be formed without the assistance of heathenish deities. No; if in the hands of Homer such admirable use could be made of the pagan mythology, which is a system only of absurdities; how much more noble and sublime a machinery would a poet of equal genius frame from the christian religion! With what energy, what masterly force, would he paint the God who created the universe with a word, who rides on the wings of the wind, and sees and comprehends every thing at a glance? How delightful must it be to follow such a poet,

ACT

while with a soul inflamed with prophetic fire, he describes his hero imagining, attempting, and executing the grandest exploits; always under the direction of some ministering angel, some guardian spirit, which gives him prudence to foresee, fortitude to encounter, and patience and courage to surmount every obstacle in his way! See *MACHINERY*.

The fourth qualification essential to the epic action, is that it should be probable: for though it seems necessary in a poem of this nature to make use of the agency of superior beings to produce effects astonishing and supernatural, yet they should never be employed in matters that contradict any known truths, or even received opinions. The poet declares himself inspired by a genius, who assists at the council of the gods; and therefore may fairly be allowed to lay open the unknown springs of great operations. But he never does it in such a manner as shocks probability; he shews us such things as resemble those we believe, and relates them with an air of authority and resolution. The resolution shakes, and the probability of the thing convinces us. We behold heroes, actions, manners, painted in characters we understand; we forgive the fiction, nay, we even forget it, through an amiable delusion that possesses us. But this would be impossible, if the characters were unnatural, or his representations exceeded the bounds of probability: in such cases we should laugh, as we do at Homer himself, when he makes a river quit his bed to pursue a man, and Vulcan run armed with fire to force the river back again to its channel.

The last thing that is necessary to the epic action is, that it should be interesting: this may be effected two ways, one, by the nature of the action and its object, and the other, by the nature of the obstacles to be surmounted: the former is called the affecting; the latter excites our curiosity, and is therefore called the singular.

The affecting comprehends several sorts of interests; as first, a national interest; thus a Roman interests himself in the undertaking of *Æneas*, as being a Roman: secondly, a religious interest; a christian interests himself in the undertaking of Godfrey of Bulloigne to deliver the sepulchre of Jesus Christ out of the hands of the infidels: thirdly, a natural interest, or the interest of humanity, "*Homo sum, humani nihil a me alienum puto*:" thus we all interest ourselves warmly in the distress of *ADAM*, not only as he is a man, but as he is the father of all mankind, in whose welfare every individual is concerned as a principal. Where these different kinds of interests can be blended and joined together, the action cannot fail to affect and captivate us. The last of these is by far the strongest and most prevalent; and Milton has chosen such a subject, in which we

ACT

are concerned both for ourselves and others, and managed it with so much art and address, that he will be for ever read and felt, even though the days of monkish barbarism should again return, when Homer and Virgil will be suffered to moulder into dust, neglected and forgotten!

We are told by Aristotle that the epic action should have a beginning, a middle, and an end; which precept F. Bossu has explained in the following manner: The beginning, says he, comprehends those causes that influence the action, and the resolution that some person takes to perform it; the middle is the effect of those causes, and the difficulties which attend their being carried into execution; and the end is the unravelling and cessation of those difficulties. The unravelling may be brought about two ways, either by discovery, or without it by a revolution. This is called a *peripetia*; which if it happen by a discovery, the *peripetia* is twofold; if by a revolution, it is single.

ACTION, in oratory, means the outward deportment of the orator, or an accommodation of his countenance, voice, and gesture, to the subject of which he is treating. Cicero emphatically terms it, the eloquence of the body: and it was so much esteemed by Demosthenes, that when he was asked, what was the principal perfection of an orator? He answered, *Action*. What the second? *Action*. What the third? *Action*. As if the matter of the discourse was of trivial consequence, so that it was only well delivered. Indeed he seems to have spoken thus with some reason, as action is a direct attack upon the senses, which are as it were the inlets to those ideas that more immediately affect the passions. For this cause it has been condemned by many sober and judicious persons, as inverting the natural order of things, dragging our reason after our passions, which should ever go before them.

It is impossible to lay down any rules to ascertain the proper modes and degrees of action, which can be *universally* just and accurate; because every nation has some particular signs of its own to express particular passions, and no two nations agree in the direct quantity of action that can be made use of with propriety. What in Italy is decent and becoming, would be regarded in France as extravagant and preposterous; and what with them is lively and spirited, is looked upon in England as downright grimace and buffoonery. Yet notwithstanding this, there are some gestures that are universally understood, and seem to be the language of nature herself; even so far that the very brutes are affected by them. The face, according to Quintilian, is able to express every movement and passion of the soul; it threatens, caresses, and supplicates; is sorrowful, gay, and humble. Nay, the very eyes with him

ACT

are a never failing source of eloquence; they are the windows of the soul, through which we see whether she sparkles with joy, or is clouded with sorrow: they are bright with pleasure, glare with indignation, are depressed with shame, roll in anger, and are tender and bathed with tears in pity.

It is much to be lamented that action is so generally disused in discourses from the pulpit; which are for the most part frigid lectures of divinity, delivered and heard without the least marks of feeling, either in the preacher or the audience. It would be highly absurd to introduce into the pulpit all the variety of theatrical gestures; but at the same time there is a certain degree of action, properly regulated, which might be made use of with the happiest success; as not unlikely to influence those who have shut their ears against the voice of reason.

ACTION, in ethics, implies something done by a free or moral agent, capable of distinguishing good from evil.

The essence of a moral action consists in being done knowingly and voluntarily: that is, the agent must not only be able to distinguish whether it be good or bad in itself, but he must likewise be entirely free from compulsion of any kind, and at full liberty to follow the dictates of his own understanding. Hence the actions of ideots, slaves, &c. cannot be called moral. Hence also appears the absurdity of fatalism, because it destroys the very foundation of morality.

ACTION, in mechanics and physics, in some authors, signifies the pressure or percussion of one body against another: or, according to others, the effect itself of such pressure.

It is absolutely necessary, in order to reason justly upon any subject, to have a just and determinate idea of it; and as this word is become ambiguous, and used both in a simple and complex sense, it was necessary to give this double definition of it: but its proper signification seems to imply the motion which a body really produces, or tends to produce in another; or in other words, that which it would have produced, had nothing hindered its effects.

For it may be considered, that we can have no demonstrative evidence of the action of bodies upon one another but their motion; and as the mind can have no precise idea of a cause, but from the effect which it produces, it would therefore be absurd to prefix any idea to the word action, except that of actual motion, or a tendency thereto. Had Leibnitz and his followers but thoroughly considered this, it is very probable we should never have heard of the famous controversy concerning the *vires vivæ*, which seems to have arose entirely from a misconception of this nature.

Quantity of ACTION, a name given by M. de Maupertuis, in the Memoirs of the Parisian academy of sciences for 1744, and in those of Berlin for 1746, to the product of the mass of a body, into the space which it runs through, and into its celerity. He there lays it down as a general law, "That in the changes made in the state of any body, the quantity of action necessary to produce such change is the least possible." This principle he applies to the investigation of the laws of refraction, equilibrium, and even to the laws of acting of the supreme Being.

In the same year that M. de Maupertuis communicated the idea of this principle, professor Euler printed a work, entitled, *Methodus inveniendi lineas curvas maximi vel minimi proprietate gaudentes*; in the supplement to which he has made an application of this principle to the motion of the planets.

It appears from the Memoir of 1744, that it was reflections on the laws of refraction which first led M. de Maupertuis to the theorem here spoken of. The principle on which M. de Fermat, and after him M. Leibnitz, accounted for the laws of refraction, by supposing that a particle of light in passing from one point to another, through two different mediums, in each of which it moves with a different velocity, must do it in the least time possible, and from whence they demonstrated by geometry, that the particle cannot go from one point to the other in a right line, but that when it arrives at the surface which separates the two mediums, it must alter its direction in such a manner, that the sine of its incidence shall be to the sine of its refraction, as its velocity in the first medium is to its velocity in the second; and from whence also they deduced the well-known law of the constant ratio of their sines, is very ingenious; but notwithstanding, M. de Maupertuis saw it was liable to one great objection, which is, that the particle must approach towards the perpendicular in that medium where its velocity is the least, and consequently resists it the most, which is contrary to all the mechanical explanations of the refraction of bodies that have hitherto been given, and of the refraction of light in particular.

Now Sir Isaac Newton's way of accounting for it is much more satisfactory, and gives a clear reason for the constant ratio of the sines, by ascribing the refraction to the attractive power of the mediums; whence it follows, that the densest mediums, whose attraction is the strongest, should cause the ray to approach towards the perpendicular, a fact confirmed by experiment. Now the attraction of the medium could not cause the ray to approach the perpendicular, without increasing its velocity, as may easily be demonstrated; and M. de Maupertuis has attempted to reconcile it

with metaphysical principles in the following manner.

Instead of supposing, as the aforesaid gentlemen do, that a particle of light proceeds from one point to another in the shortest time possible; he will have it, that a particle of light passes from one point to another in such manner, that the *quantity of action* shall be the least possible. This quantity of action, says he, is a real expence, in which nature is always frugal; and in virtue of this philosophical principle, he discovers that not only the sines are in a constant ratio, but that they are also in the inverse ratio of their velocities; agreeable to Sir Isaac Newton's explanation, and not in the direct ratio, as Messieurs de Fermat and Leibnitz had supposed.

It is very remarkable that of the many philosophers who have written on refraction, none should hit upon this thought; for it is but making a small alteration in the calculus founded on M. de Fermat's principle, viz. That the space divided by the velocity should be a minimum: for calling the space run through in the first medium S with the velocity V ; and the space run through in the second medium s with the velocity v , we shall have $\frac{S}{V} + \frac{s}{v}$ a minimum, its fluxion $\frac{\dot{S}}{V} + \frac{\dot{s}}{v} = 0$; whence it is easy to perceive, that the sines of incidence and refraction are to each other as $\dot{S}$ to $-\dot{s}$; it follows that those sines are in the direct ratio of $V : v$, which is what M. de Fermat makes it to be: but in order to have those sines in the inverse ratio, it is only supposing that $S \times V + s \times v$ is a minimum, which gives $\dot{S}V + \dot{s}v = 0$. See MINIMUM and FLUXION.

In the Memoirs of the academy of Berlin above-cited, may be seen all the other applications which M. de Maupertuis has made of this principle; and whatever shall be determined with regard either to his metaphysical basis, or the conception he has annexed to the quantity of action, it will still hold good, that the product of the space by the velocity is a minimum, in the most general laws of nature.

ACTION, in the animal œconomy, is a motion or alteration produced in the whole body, or in some part of it, and differs from function in this, that the latter is only a faculty of producing, whereas action is that faculty reduced into an act, *Boerhaave*.

ACTIONS, as well as functions, are distinguished into vital, natural, and animal: the vital actions are those which are of an absolute necessity for life; such as the motion of the heart, respiration, &c. Natural actions are those whereby the body is preserved such as it is; such are digestion, the secretions, nutrition, &c. The animal actions are those which produce a certain alteration in

ACT

the soul, and on which it hath some power; such are the motion of the muscles submitted to the will, sensations, &c. See *FUNCTION*, *Animal*, *Natural* and *Vital*.

ACTION, in medicine, is said in the same sense as function; and therefore we say, that the action of the stomach upon aliments is to divide them and mix them intimately together. A physician ought to be acquainted with the action of all the parts of the human body, and to distinguish the cause, seat, and differences of diseases; this knowledge puts him in a situation of pronouncing with certainty, either in respect of the danger that the patient is in, or of the proximity of his recovery. See *FUNCTION*.

The word action is likewise medicinally used instead of force: we augment the action of a purgative, by adding something to it, that is to say, we give it more force.

ACTION, in the military art, is an engagement between two armies, or between different bodies of troops belonging thereto. The word is likewise used to signify some memorable act done by an officer, or commander of a body of troops.

ACTION, in law, is a judiciary demand, founded upon a title or law, whereby the plaintiff summons the defendant to satisfy him for that to which he is obliged, in virtue of the one or the other, and for defect whereof he requires that he should be condemned by the judge.

ACTIONS are divided by Justinian into two general kinds, real, or those against the thing; and personal, or those against the person; for whoever brings an action, either does it against one obnoxious to him in respect either of contract or of offence; in which case arise actions against the person, which require the party to do or give something; or he does it against one not obnoxious, yet with whom a controversy is risen touching some matter; as if Caius holds a field, which Julius claims as his property, and brings his action for the same. See the *INSITU*. *L. 4. tit. 4.* where the principal actions introduced by the Roman law are summarily explained.

There is also a third kind of action which arises out of the two former classes of real and personal actions, and which is called a mixed action.

Real ACTION is that whereby the plaintiff sues for the right which he has to lands, tenements, rents, or other payments; and of this there are two sorts, either the possession or demand. An action is merely real when it singly attacks the thing, and the detainer is clear upon giving it up; but if he is personally obliged to the restitution of fruits or interest, in that case it is mixed.

Personal ACTION is that which one man has against another, in consequence of a contract, whereby he is obliged to pay or do something;

ACT

or by reason of an offence done by him, or by some other person for whose fact he is answerable. See *PERSONAL*.

In the first case the action is civil, and in the other it is or may be criminal.

Mixed ACTION is that which is either laid against the person of the detainer of the thing, or for the thing detained, being thus called, because it hath a mixed respect, both to the thing and to the person.

They generally reckon three sorts of mixed actions, the action of partition between coheirs, of division between associates, and limitations between neighbours.

ACTIONS are also divided into civil, penal, or criminal: the civil action is that which tends only to the recovery of that which belongs to a man, by virtue of a contract, or of some such like cause; as if any one should endeavour to recover, by way of action, a sum of money which he has lent.

Penal or criminal ACTION tends to the punishment of the party accused or prosecuted, either corporally or pecuniarily.

ACTION of a writ, is where a person pleads some matter, whereby he shews that the plaintiff hath no just cause to have the writ he brought, though it be possible he might have a writ or action for the same matter; such plea is called a plea to the action of the writ. See *WRIT*.

ACTION, in commerce, sometimes signifies moveable effects; and we say, that the merchant's creditors have seized upon all his actions, instead of saying, that they have put themselves in possession, and rendered themselves masters of all his active debts.

ACTION, in painting and sculpture, is the attitude or position of the parts of the face and body of such figures as are represented, and whereby we judge that they are agitated by passions: they say, This figure by its action finely expresses the passions with which it is agitated; This action of a man in a fright is very well. They make use of the same term in respect to animals; they say, There is a dog, whose action very well expresses fury; and of a stag at bay; There is a stag, who by his action expresses his grief, &c.

ACTIVE, in a general sense, implies something that communicates motion or action to another, in which acceptation the term active stands opposed to passive.

ACTIVE, a term in grammar, which denotes a word that has an active signification, or expresses an action.

Verbs active, according to some grammarians, are distinguished into three kinds: first, *transitive*, where the action passes into a subject different from the agent, as Antony loved Cleopatra: secondly, *The reflected*, or verb *neuter*, which has no noun following

following it, because the action returns upon the agent, as I walk, I think, &c. and thirdly, The *reciprocal verb*, which is used only in some modern languages, where the action turns mutually upon the several agents who produced it, as in French, *Jaque et toi vous vous aimez*: "James and you commend each other, or one another."

In the Greek and Latin languages, the active and passive voice have each their distinct terminations in the different moods and tenses: but in all modern languages, the passive voice is expressed by the participle past joined to an auxiliary verb, as, I am loved. See PARTICIPLE, AUXILIARY, &c.

ACTIVE principles, in chemistry, those which act of themselves without any foreign assistance. These are supposed to be mercury, oil, and salt; phlegm and earth are called passive principles.

ACTIVITY, in a general sense, signifies the faculty or power which renders things active.

Sphere of ACTIVITY, the whole space in which the virtue, power, or influence of any object is exerted.

ACTŒA, in botany, a name given by Linnaeus to a plant, formerly called *Christophoriana* by Tournefort, or herb Christopher. It produces a roseaceous flower composed of four petals; the filaments are numerous and hairy, topped with round and upright antheræ; it has no style, but the germen, which is oval and placed in the center, is crowned with an oblique compressed stigma. When the flower is decayed, its ovary becomes a globular berry consisting of one cell, containing four seeds, whose outsidés are round, but angular where they are joined. The common sort, called bane-berries, grows plentifully in some parts of Yorkshire: but the other species of this plant are natives of America, one of which called black snake-root, is used as an antidote against the bite of the rattle-snake.

ACTOR, in a general sense, signifies a person who acts or performs something.

ACTOR, as to the drama, signifies a person who represents some part or character upon the theatre.

The drama consisted originally of nothing more than a simple chorus, who sung hymns in honour of Bacchus. Thepis was the first who introduced a *persona* or actor; which he did for two reasons, one, to give a kind of respite, or breathing-time to the singers, and the other, to explain some particular circumstances which related to their heroes, and without which several passages in their hymns would not easily be understood. Æschylus, finding a single person tiresome, ventured to introduce a second; and so changed the ancient recitals into dialogues. It was he who first invented the buskin, which was a high shoe,

that encreased the stature, and gave the wearer an heroic appearance.

Sophocles improved further upon this plan; and finding the two persons of Æschylus not sufficient for the variety of incidents, added a third: and here the Greeks stopped; at least we do not find in any of their tragedies above three persons in the same scene. In their comedies, they allowed themselves greater licence.

If we consider some particular circumstances and customs that prevailed on the ancient theatre, we cannot help supposing that the actors trusted rather to the matter of the play, than their manner of performing it, for the entertaining and affecting their audience. In the first place they acted in masks, for which reason they were called *personæ*: now it was impossible for them to express any emotion of the soul by the muscles of the face, which is the most eloquent part of the body, while it was thus concealed from the spectators. To remedy this inconvenience, when the actor was to vary the passion, he wore a mask that was painted, on one side the face, for instance, to represent joy, and on the other grief: and when there was occasion to make a transition from one passion to the other, he gave himself a dexterous turn, and exhibited the opposite profile.

Another thing, which to us at least appears highly ridiculous, is, that on the Roman stage one actor frequently spoke the part, and another gave it a proper accompaniment of action and gesture.

Actors were highly honoured at Athens, and despised at Rome; where they were not only denied all rank among the citizens, but even when a citizen appeared upon the stage, he was expelled his tribe, and deprived of the right of suffrage by the censors. The French have in some measure adopted the same ideas with the Romans; but we, more humane and polite, those of the courtly Athenians.

ACTUAL, an epithet applied to such things as exist fully and absolutely. Thus philosophers speak of actual heat, cold, &c. in opposition to virtual or potential.

ACTUARIE navis, in antiquity, a kind of ships among the Romans, designed chiefly for expedition.

ACUBENE, in astronomy, the Arabic name of a star of the fourth magnitude, in the southern forceps of cancer; by Bayer marked α . See the constellation CANCER.

ACUPUNCTURE, a method of curing several disorders among the Chinese and Japanese. It consists in making a great number of punctures in the part affected with a gold or silver needle.

ACUS, in ichthyology, the name of two distinct genera of fishes; the one called the acus of Aristotle,

Aristotle, and the other the acus of Bellonius. The former is generally called in English the needle-fish, and the latter the gar-fish.

ACUTE, an epithet applied to such objects as terminate in a sharp point or edge; in which acceptation it is opposed to obtuse.

ACUTE Angle, in geometry, is that which is less than a right-angle, or ninety degrees. See ANGLE.

ACUTE-angled Cone, is a right cone, whose axis makes an acute angle with its sides.

ACUTE-angled Triangle, in geometry, is that whose angles are all acute: it is otherwise called an oxigonous triangle. See TRIANGLE.

ACUTE angular section of a cone, an expression made use of by the ancient geometers, to signify the ellipsis. See CONE, and ELLIPSIS.

ACUTE Accent, in grammar. See ACCENT.

ACUTE, in music, is applied to a tone or sound that is sharp or high, in respect to some other tone. In this sense it stands opposed to grave.

ACUTE Diseases, among physicians, imply such as move with velocity towards a crisis, and are attended with danger. In this sense the word acute is opposed to chronic.

Ad, in grammar, a Latin preposition, frequently used in the composition of words in the English as well as the Latin language. Sometimes the *d* is suppressed, and sometimes changed into another letter.

ADAGE, a short sentence, or proverb, containing some wise remark, or useful observation.

We have a collection of Greek and Roman adages, by Erasmus, and another of English proverbs, by Mr. Ray.

ADAGIO, an Italian adverb, signifying slowly, leisurely; and is used in music, to signify the slowest of all times, except the grave. It is sometimes repeated, as *adagio*, *adagio*, and then signifies a still greater retardation of the time than when used singly.

ADAMANT, a name sometimes given to the diamond. See DIAMOND.

ADAMI Pomum, Adam's apple, in anatomy, a prominence in the fore part of the throat; so called from an idle conceit that a piece of the forbidden fruit stuck in Adam's throat, and occasioned this tumor; though it is in reality nothing more than the convex part of the first cartilage of the larynx. See LARYNX.

ADAMICA Terra, adamic earth, a name given to the common clay, from a supposition of its being the adamah, or ruddy earth, out of which the first man was formed.

Some writers call the slimy substance found at the bottom of the sea by the name of *Adamica terra*.

ADAMITES, the name of a sect of ancient heretics, who are mentioned by Epiphanius, and

after him by St. Austin and Theodoret: they are supposed to be a branch of the Basilidians and Carpocratians. It is much disputed amongst the learned at what time this sect first sprang up, and who was its author. Some affirm, that it began in the second century of the church, and that its instructor was Prodicus, a disciple of Carpocrates: but it appears from Tertullian, and Clement of Alexandria, that his followers never had the name of Adamites, though they professed the same errors.

However this might be, they took the name of Adamites, according to Epiphanius, from their pretending to be reinstated in primitive innocence, like Adam at his first creation, whose nakedness they thought themselves obliged to imitate. They detested marriage, affirming that the conjugal union had never been known but for sin; and that the privilege of enjoying women in common belonged to those who like them were reinstated in original purity. However incompatible these tenets were with chastity, they all of them pretended to vast continence, and declared that if any of their followers fell into carnal sins, they would chase him from their assembly, as Adam and Eve were driven out of paradise for eating the forbidden fruit. They looked upon themselves as so many Adams and Eves, and their temple as paradise: a strange paradise indeed, which was nothing but a subterraneous cavern, into which they entered stark naked, men and women; and as soon as ever their chief had pronounced aloud, "Increase and multiply," committed the most scandalous actions, even adultery and incest! They had not even regard to common decency, but openly in the face of the sun imitated the beastly impudence of the ancient Cynics. They boasted that they were possessed of the secret books of Zoroaster, for which reason they have been suspected by some of practising magic arts.

This detestable sect did not at first continue long, but started up afresh in the twelfth century, under one Tandamus, since known by the name of Tanchelin. They appeared again in the fifteenth century, under one Picard, who pretended that he was sent into the world as another Adam, to re-establish the law of nature, which, according to him, consisted in going naked, and having all the women in common. They assembled, like the votaries of the *Bona Dea* (only that there were men as well as women) by night, and like them too had their secrets and mysteries. One of the fundamental maxims of their society was contained in the following verse:

Jura, perjura, secretum prodere noli.

Some learned men have thought that this sect is very ancient, and trace them up as high as the followers and votaries of the heathen god Priapus.

ADANSONIA, in botany, a tender kind of gourd,

gourd, said to come originally from Ethiopia. It consists of a flower whose cup is monophylous; the petals are five in number, round and fleshy; the filaments are numerous, surrounding a long tubulous crooked style; and the fruit is a hard oval shell, covered with down, which contains seeds similar to chocolate nuts, and of a dusky colour.

ADAPTERS, in chemistry, are hollow vessels, of an oblong form, perforated at each extremity, for connecting the receiver to the nose of the retort, alembic, &c.

ADAR, the name of a Hebrew month, which answers to part of our February and March: it is the twelfth of their sacred, and the sixth of their civil year.

On the seventh of this month the Jews celebrate a fast, in commemoration of the death of Moses.

They do the same on the thirteenth, which they call the fast of Esther; and on the fourteenth they hold the feast of Purim, to celebrate their deliverance from the cruelties of Haman by means of Esther.

As the lunar year, which the Jews have been used to follow in their calculations, is shorter than the solar by eleven days, they insert at the end of every three years an intercalary month of twenty-nine days, which they call Veadar, or the second Adar.

ADARCE, in the ancient materia medica, was a kind of salt concreted about reeds and other vegetables in form of incrustations.—It was applied externally in various cutaneous disorders, as a detergent and dissolver.

ADARTICULATION, a term used by some writers in anatomy, for what is more generally called arthrodia, and diarthrosis.

ADERAMIN, in astronomy, the Arabic name of a star of the third magnitude, in the left shoulder of Cepheus, marked α by Bayer. See the constellation CEPHEUS.

ADDER, in zoology, a name sometimes given to the viper. See VIPER.

ADDERS-TONGUE, *Ophioglossum*, in botany. See OPHIOGLOSSUM.

ADDER-WORT, in botany, the same with Bistort, or snake-weed. See BISTORT.

ADDICE, or ADZE, a kind of crooked ax used by shipwrights, carpenters, coopers, &c.

ADDITION, in a general sense implies the uniting or joining several things together; or, the adding something to another.

ADDITION, in arithmetic, is the first of the four fundamental or principal rules of that science, whereby we are taught to find a sum equal to several small ones.

In setting down the numbers to be added, care must be taken to place every figure in its proper

place, that is, units under units, tens under tens, &c. Then will the reason of the work appear very evident from this undeniable maxim, viz. that all the parts are equal to the whole. And the method of setting down the total may easily be accounted for from the nature of numeration, which explains the different value of places, as they proceed from the right to the left-hand; for as 9 is the greatest simple character or figure, so every number exceeding 9, being compound, must require more places than one to express it.—Thus the number ten can no otherwise be expressed in figures but by removing the figure 1 into the place of tens, which is done by supplying the units place with a cypher; and as it is the same with every other column (ten being still the proportion of increase) consequently when the sum of any column amounts to 10 or more, the units exceeding, if there be any, or a cypher, if none, must be set under such column, and the ten or tens carried on as so many units to the next column on the left-hand; for example, suppose we were to add the numbers 47, 397, and 687, together, they must be placed in the following manner, one under another:

47	
397	
687	
—	
1131	

Having thus placed the above numbers, draw a straight line under them, and beginning at the place of units, add all the figures together in that column, putting their sum under the said straight line; as in this example, say, seven and seven make fourteen, and seven make twenty-one; wherefore, put one under the line in units place, and carry two for the two tens to the next column, and then proceed, saying, two that I carry and eight is ten, and nine is nineteen, and four make twenty-three, set down three under the line in tens place, and carry two to the next column; then say, two and six is eight, and three make eleven, which, because it is the last column, put down eleven, and the work is done.

ADDITION of different denominations. When the numbers are of different denominations, or when they contain, for example, pounds, shillings, pence, and farthings; tons, hundreds, quarters, pounds, &c. care must be taken to place the given numbers in such order under each other, that each column, from top to bottom, may consist of one and the same value, as pence under pence, shillings under shillings, and pounds under pounds.

Having first drawn a line under the columns, add them together, considering how many of each smaller make an unit of the next that is superior to it, (always observing to begin at the least denomination) and for every such unit carry one to the next superior denomination, that is, for every 4

ADD

in the farthings, you must carry one to the pence; for every 12 in the pence column carry one to the shillings column; and for every 20 contained in the shillings, carry one to the pounds, and the odd farthings, pence, and shillings, put under their proper columns below the line, as in the following examples.—Let it be required to add together, 146*l.* 16*s.* 7 $\frac{1}{4}$ *d.* 274*l.* 10*s.* 11 $\frac{3}{4}$ *d.* 567*l.* 17*s.* 10 $\frac{1}{2}$ *d.* and 78*l.* 11*s.* 6 $\frac{1}{4}$ *d.* First set them down one under the other, in the following manner, and draw a line as before directed,

<i>l.</i>	<i>s.</i>	<i>d.</i>
146	16	7 $\frac{1}{4}$
274	10	11 $\frac{3}{4}$
567	17	10 $\frac{1}{2}$
78	11	6 $\frac{1}{4}$
1067	17	0 $\frac{1}{4}$

First begin with the least denomination, which is farthings, and add them together, saying $\frac{1}{4}$ and $\frac{3}{4}$ is $\frac{1}{2}$, and $\frac{1}{2}$ is 6, and $\frac{1}{4}$ make 9, which is 2 pence and one farthing over, which set down under farthings below the line, and carry the 2 to the pence; then say, 2 and 6 is 8, and 10 is 18, and 11 is 29, and 7 make 36, which is 3 shillings, and nothing over; therefore put down nothing under the pence column, and carry 3 to the shillings; then say, 3 and 11 is 14, and 17 is 31, and 10 is 14, and 16 is 57, which makes 2 pounds, and 17 shillings over; put down the 17 shillings under shillings, and carry 2 to the pounds, saying 2 and 8 is 10, and 7 is 17, and 4 is 21, and 6 make 27, which is 2 tens, and 7 over; therefore put down a 7 under the units place of the pounds, and carry 2 to the tens, and say, 2 and 7 is 9, and 6 is 15, and 7 is 22, and 4 is 26; put down the 6, and carry 2 to the next column, saying, 2 and 5 is 7, and 2 is 9, and 1 is 10, which place down under the line in such a manner that the cypher may stand under the last column of the pounds, and the 1 to the left-hand, and the work is done.—Note, that whatsoever sums are to be added together, whether of money, weights, measures, &c. when you come to the greatest denominations, as you cast up the several columns thereof, you are to carry the tens of every preceding column to that which follows.

ADDITION of Decimal Numbers does nowadays differ from that of integers, due care being taken to place the particular sums so that the first place of the integral or decimal parts be exactly under each other, as is seen in the following example :

4789,73
5684,94
3415,63
28,48
13918,78

ADD

Cyphers on the right-hand of a decimal number signify nothing, and are therefore more elegantly omitted; thus,

Instead of	$\left\{ \begin{array}{l} 47.080 \\ 56.700 \\ 4.506 \\ 4.120 \end{array} \right\}$	We write	$\left\{ \begin{array}{l} 47.08 \\ 56.7 \\ 4.506 \\ 4.12 \end{array} \right\}$
	$\frac{112.406}{112.406}$		

See the article DECIMALS.

ADDITION of Vulgar Fractions. When the fractions to be added have one common denominator, add the numerators together for a new numerator, and place it over the given common denominator; thus $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{2}{3}$, when added together, make $\frac{3}{6}$, or $\frac{1}{2}$; but when amongst the given fractions there are either compound ones, or single with different denominators, they must be prepared by reduction before they can be added. See FRACTIONS, and Reduction of FRACTIONS.

ADDITION, in algebra, is performed by connecting the quantities to be added with their proper signs or character of + and —, and uniting or joining together those which are similar and capable of it. See SIMILAR, ALGEBRA, and CHARACTER.

The difficulty in algebraic additions, will chiefly arise from the signs + and — made use of in them; but only conceive, that what + affirms — denies, or what the first alledges or brings, the second annuls and takes away; if + makes a tradesman worth such a sum, — deprives him of it again: let us suppose a person has in possession 20 pounds, and that he owes 10 pounds, then it is plain that his real worth is only 10 pounds; so in algebra, + 20 added to — 10, the sum will be equal to 10. Addition of algebra may be reduced to the following rules:

RULE I.

When the letters, called quantities, are the same, and have the same sign prefixed, add the quantities together, and to the sum prefix the common sign.

Example 1.	Example 2.	Example 3.
$a = 4$	$-b = -2$	$a - b = 4 - 2$
$3a = 12$	$-5b = -10$	$3a - 5b = 12 - 10$
$4a = 16$	$-6b = 12$	$4a - 6b = 16 - 12$

Numbers represented by the same letter in any operation, are supposed to be of the same value, and those by different letters of different values: thus in example third, the letter *a* represents 4, and *b* represents 2; again the figure or number, prefixed to any letter or quantity, (called its co-efficient) shews how often that quantity is to be taken; thus, 3*a* shews that the quantity represented by *a* is to be taken 3 times, and when a quantity stands without a co-efficient, it is always understood to have

ADD

have an unit prefixed. Quantities which differ only in their co-efficients, (as a , $3a$ and $5a$) are said to be like or similar, but $3a$ and $5b$ are unlike, and not similar. Quantities which stand without any prefixed sign before them, are always understood to have the sign $+$ before them: thus, $3a$ and $+3a$, both represent the same thing.

RULE II.

When the quantities are like, but have different signs; subtract the co-efficient of the lesser from that of the greater, and to the difference, if any prefix the sign of the greater, adjoining the letter or letters, common to each quantity.

Example 4.	Example 5.	Example 6.
$-a = -7$	$b = 11$	$5b - a = 55 - 7$
$3a = 21$	$-4b = -44$	$-2b + 3a = -22 + 21$
$2a = 14$	$-3b = -33$	$3b + 2a = 33 + 14$

RULE III.

When the quantities are unlike, set them in order with their proper signs prefixed.

Example 7.	Example 8.	Example 9.
$a + b$	$4x - 5y$	$7z - x - a$
$a - c$	$2n - z$	$7z - d + c$
$2a + b - c$	$4x + 5y + 2n - z$	$14z - x - a - d + c$

ADDITION of algebraic fractions is performed by the same rules as numerical fractions, they being first reduced to one denomination, and their lowest terms. See FRACTIONS.

ADDITION of surd, or irrational. In these operations we have two cases.

CASE I.

When the surd quantities are alike, add the rational parts, or those which are without the radical sign, if they are joined to any, and to their sum join their surd.

Example 1.	Example 2.
$7x\sqrt{ab}$	$5y\sqrt{dm-y}$
$5x\sqrt{ab}$	$y\sqrt{dm-y}$
$12x\sqrt{ab}$	$6y\sqrt{dm-y}$

CASE II.

When the surd quantities are unlike, they are only to be added by their signs, and from thence will arise compound surds.

Example 3.	Example 4.
$\sqrt{bx}$	$m\sqrt{da+y}$
$\sqrt{bz}$	$m\sqrt{z}$
$\sqrt{bx} + \sqrt{bz}$	$m\sqrt{da+y} + m\sqrt{z}$

ADD

In the last example, the letters under the radical signs being different, first put down $m\sqrt{da+y}$, and because the quantity $m\sqrt{z}$ has the sign $+$, therefore after $m\sqrt{da+y}$ put the sign $+$, after which put the quantity $m\sqrt{z}$, and we have $m\sqrt{da+y} + m\sqrt{z}$.

ADDITION of logarithms. See LOGARITHMS.

ADDITIONS, among distillers, a general name for such things as are added to the wash or liquor while fermenting, in order to increase the vinosity and quantity of the spirit, or to give it a particular flavour.

ADDITIONS, in law, denote all sorts of designations given to a person, over and above his proper name and surname, &c.

These additions are ordained to prevent one man's being grieved or molested for another; and that every person might be certainly known, so as to bear his own burden.

If a man is of different degrees, as duke, earl, &c. he shall have the most worthy; and the title of knight, or baronet, is part of the party's name, and therefore ought to be rightly used; whereas that of esquire, or gentleman, being as people please to call them, may be used or not, or varied at pleasure.

An earl of Ireland is no addition of honour here; nay, the law-addition to the children of British noblemen is only that of esquire, commonly called lord.

WRITS without the proper additions, if excepted to, shall abate; only where the process of out-lawry doth not lie, additions are not necessary. The addition of a parish, not in any city, must mention the county, otherwise it is not good.

ADDITION of ratios, the same with what is otherwise called composition of ratios. See COMPOSITION and RATIO.

ADDITION, in music, a dot marked on the right side of a note, to signify that it is to be sounded or lengthened half as much more as it would have been without such mark. See NOTE, and CHARACTER.

ADDITIONAL, in a general sense, denotes something over the usual sum or quantity.

ADDITIONAL Duties, those charged upon certain commodities, over and above what were formerly obliged to be paid.

ADDITIVE, in a general sense, signifies something to be added: mathematicians speak of additive ratios, astronomers of additive equations. See the articles RATIO, and EQUATION.

ADDRESS, in a general sense, denotes the nice management of an affair, or the transacting it with great propriety and skill.

ADDRESS is, more particularly, used for a speech made to the king, in the name of some considerable body of men, by way of congratulation, petition, or remonstrance.

Addresses

Addreses of parliament were first set on foot under Oliver Cromwel.

ADDUCENT *Muscles*, among anatomists, the same with those more usually called adductors. See **ADDUCTOR**.

ADDITION, *Additio*, among anatomists, denotes the action of the muscles called *adductores*. See **ADDUCTOR**.

ADDUCTOR, in anatomy, a general name for all such muscles as serve to draw one part of the body towards another. Thus,

ADDUCTOR brachii is a muscle of the arm, serving to bring it towards the trunk of the body.

ADDUCTOR indicis, a muscle of the fore-finger, which draws it towards the thumb.

ADDUCTOR oculi, a muscle of the eye, directing its pupil towards the nose; and otherwise called *bibitorius*, for a like reason.

Anatomists reckon up several other abductors, as the *adductor pollicis*, the *adductor pollicis pedis*, *adductor minimi digiti pedis*, *adductor prostaticæ*, &c.

ADELPHIANI, in church history, a sect of heretics, who always fasted on Sundays.

ADEMPTION, *ademptio*, among civilians, denotes the revocation of some donation or favour.

The ademption of a legacy may be done either in express terms, or indirectly, by disposing of it otherwise.

ADENOGRAPHY, *adenographia*, that part of anatomy which treats of the glands. See **GLAND**.

ADEPS, in anatomy, denotes the fat found in the abdomen; differing from the common fat, or *pinguedo*, as being thicker, harder, and of a more earthy substance.

ADEPS, among physicians, is used in a more general sense, for all kinds of animal fat: these they prescribe for their ripening quality.

ADEPTS, the name given to the proficient in alchemy, particularly those who pretend to have found out the philosophers stone, and the panacea, or universal medicine.

Alchemists will have it, that there are always twelve adepts; the places of those who die being immediately supplied by others of the fraternity.

ADEQUATE, in a general sense, something exactly corresponding with another. Thus,

ADEQUATE Ideas are those which perfectly represent all the parts and properties of the object. See **IDEA**.

In this sense, the idea of a figure bounded by a curve line, which returns into itself, and whose parts are all equally distant from a certain point in the middle, is an adequate idea of a circle.

All simple and abstracted ideas are adequate ones, because they represent objects as they really are: whereas those of substances are inadequate, in regard our knowledge of substance is extremely defective.

ADESSENARIANS, *Adessenarii*, a sect of Christians, who maintain that Jesus Christ is really present in the eucharist, though not by way of transubstantiation.

The Adessenarians differ among themselves, some of them holding, that the body of Jesus Christ is in the bread; others, that it is about the bread; others, that it is with the bread; and others, that it is under the bread. See **EUCARIST**.

AFFECTED Equations, or affected, in algebra; those wherein the unknown quantity is found to rise to two or more different powers: for example, $z^3 + az^2 - bz = a^2qn$, in which there is found three different powers of z , that is, z^3 , z^2 and z . See **EQUATION**.

The term *affected* is sometimes likewise used in algebra, when speaking of quantities which have co-efficients. Thus in the quantity $3x$, x is said to be affected with the co-efficient 3.

It is likewise said, that an algebraic quantity is affected with the sign + or —, or with a radical sign $\sqrt{}$; meaning that it has the sign + or —, or that it includes a radical sign $\sqrt{}$. See **CO-EFFICIENT** and **RADICAL**.

ADHESION, in physics, the state of two bodies joined or fastened together by mutual attraction, the interposition of their own parts, or the impulse or pressure of external bodies. Muschenbroeck in his *Essai de Physique*, has given a great many remarks on the *adhesion* of bodies, and relates various experiments which he had made on this matter; the chief of which concern the resistance of several bodies to fracture, in virtue of the adhesion of their parts; which adhesion he ascribes, principally, to their mutual attraction. Common experiments prove the mutual adhesion of the parts of water to each other, as well as to the bodies they touch. The same may be said of the particles of air, on which M. Petit has a memoir, among those of the academy of sciences at Paris, for the year 1731. Some authors seem not disposed to admit, that the adhesion of the parts of water, on indeed of bodies in general, is to be attributed to the attraction of their parts, and they reason thus: Suppose, say they, attraction to act at the distance of a line from a particle of water, about this particle describe a circle whose radius is one line; the particle of water will not be attracted but by the particles which are included within the circle, and as these particles act in contrary directions, their mutual effects must destroy one another, and there can be no attraction of the particle, since it will have no more tendency one way than the other. See **ATTRACTION** of *Cohesion*.

ADHESION, among logicians, denotes the maintaining some tenet, merely on account of its supposed advantage, without any positive evidence for its truth,

ADHESION, in medicine and anatomy. There are frequent instances of the adhesion of the lungs to the pleura and diaphragm, which occasions many disorders. We also read of adhesions of the intestines, of the dura mater to the cranium, &c.

ADANTIUM, in botany, maiden-hair. See **MAIDEN-HAIR**.

ADIAPHORISTS, or *Adiaphorites*, in church history, names given to the moderate Lutherans, in the sixteenth century.

The name imports lukewarmness, or indifference; being compounded of the privative *α*, and *διαφορα*, different.

ADJACENT, in geometry, whatsoever lies immediately near each other: an angle is said to be adjacent to another angle, when the one is immediately contiguous to the other, so that they both have one common side. This term is more particularly used when the two angles have not only one common side, but also when the two other sides form one right line. See **ANGLE**, and **SIDE**.

ADJECTIVE is a term made use of in grammar, and comes from the Latin word *adjectus*, added *α*, because it is always joined to the noun substantive, either expressed or understood, to shew its qualities or accidents.

Some persons have improperly called the following words substantives, viz. the sublime, the grand, the beautiful, &c. They are used indeed substantively; but still are only adjectives, employed to express that idea of sublimity, grandeur, and beauty, which is raised by some substance, or agent. It was in the same manner that the Greeks and Latins made use of adjectives of the neuter gender instead of substantives: but then in this case the substantive was always understood; as in the following examples, *μῆτις ἢ πύγῃ ἐκείνης αὐτῆς οὗτος ἐβούλει το γλυκὺ καὶ το πικρὸν*; where it is evident that *ὕδωρ* is understood: and in the following passage of Horace,

----- miscuit utile dulci,

χρῆμα, or part, is to be supplied.

The definition which F. Buffier gives of adjectives is by no means a bad one, though somewhat different from other grammarians: nouns, according to him, are substantives, when the objects which they represent are considered simply and in themselves, without any regard to their qualities: on the contrary, they are adjectives when they express the quality of an object. Thus when we say simply a king, the word king is a substantive, because none of its qualities are expressed; but when we say a pious king, or a virtuous king, or a good king, these words pious, virtuous, and good are adjectives; because they express so many qualities in the king. See **NOUN SUBSTANTIVE**, &c.

AD INQUIRENDUM, in law, a writ commanding inquiry to be made about something connected with a cause depending in the king's courts; as of bastardy, for instance.

ADJOURNMENT, in law, the putting off a court or meeting to another time or place. Thus,

ADJOURNMENT in Eyre, is the appointment of a certain day, when the justices in eyre are to meet again.

ADJOURNMENTS of Parliament differ from prorogations, in being not only for a short time, but also in regard each house has the privilege of adjourning itself. See **PROROGATION**.

ADIPOSE, in a general sense, denotes something belonging to the fat of the body.

The term adipose is chiefly used by physicians and anatomists, in whose writings we read of adipose cells, adipose ducts, adipose membrane, adipose vessels, &c. See **CELL**, **DUCT**, &c.

ADIT, *Aditus*, in a general sense, signifies the passage to, or entrance of any thing. Thus we read of an adit of a mine, adit of a theatre, adit of ships, &c. See **MINE**, **THEATRE**, &c.

ADJUNCT, *Adjunctum*, among philosophers, something added to another, to which it does not naturally belong: thus water in a sponge is an adjunct to it; so are clothes to a man.

Adjuncts are what we commonly call circumstances: these, in ethics, are commonly reckoned seven, *quis, quid, ubi, quibus auxiliis, cur, quomodo, quando*.

ADJUNCTS, in rhetoric, a denomination given to all words added with a view to increase the force of the discourse: such are adjectives, attributes, epithets, &c.

ADJUNCT is also used for a colleague, or assistant. Thus,

ADJUNCT GODS, in heathen theology, were a kind of inferior deities, whose office it was to assist the superior gods: such were Mars, Bellona, and Nemesis accounted.

AD JURA REGIS, in law, a writ which lies for a clerk presented to a living by the king, against those who endeavour to eject him, to the prejudice of the king's title.

ADJUTAGE, or *Adjutage*, in hydraulics, is a tube fitted to the mouth of a jet-d'eau, through which the water is played, or directed into any desired figure; so that the great variety of fountains is chiefly owing to the different structure, &c. of their adjutages.

Mr. Mariott, who was very conversant in these things, gives the following proportions of the bores of the adjutages and pipes of conduct, dividing the inch into 12 equal parts, which he calls lines.

P

Height

Height of the re- servoirs.	Diameters of fit Ad- jutages.	Diameter of the pipes of conduct.
Feet	Lines	
5	3, 4, 5, or 6	22
10	4, 5, or 6	25
15	5 or 6	27
20	6	30
25	Ditto	33
30	Ditto	36
40	7 or 8	51
50	8 or 10	65
60	10 or 12	72
80	12 or 14	87
100	12, 14, or 15	96

There is a certain and just proportion to be observed between the adjutage, whereby the jet is delivered, and the pipe conducting it from the head. In general about five times the diameter of the adjutage for jets under half an inch, and six or seven times for all above, will size the pipes of conduct pretty well.

In reservoirs of the same altitude, and adjutages of different diameters, the expence of water is proportionable to the squares of the diameters of the adjutages. But in reservoirs of different altitudes, the excess of the expence of water from greater heights more than in smaller is in the subduplicate ratio, or as the square roots of the altitudes; from whence we have the two following tables :

TABLE I.		
Adjut.	Feet	Pints
1	1	$1\frac{1}{2}$
2	2	$6\frac{2}{9}$
3	3	14
4	4	25
5	5	29
6	6	56
7	7	$76\frac{1}{4}$
8	8	$110\frac{1}{3}$
9	9	126

TABLE II.	
Height	
6	10
8	$11\frac{1}{2}$
9	$12\frac{1}{6}$
10	$12\frac{3}{5}$
12	14
15	$15\frac{1}{2}$
18	17
20	$18\frac{1}{2}$
25	$20\frac{3}{5}$
30	$22\frac{1}{5}$
35	24
40	$24\frac{2}{3}$
45	$27\frac{1}{5}$
48	28

It is shewn from experiment, that 14 Paris pints of water will be delivered in a minute from an adjutage of three lines diameter, when the height of the reservoir above the orifice is 12 feet; which may be taken as a fundamental rule for fountains assisted with the foregoing principles. Likewise observe, that the foregoing tables of Mr. Mariott's of the expences of water are calculated for one

minute of time; and should the expence of two reservoirs of unequal heights and different adjutages be required, use the following rule :

The expence of water of two reservoirs whose altitudes are different, and also their adjutages, are in the compound ratio of the squares of the diameters of the adjutages, and of the subduplicate ratio of the heights. See the article FOUNTAIN.

ADJUTANT, in the military art, an officer whose business it is to assist the major, and therefore sometimes called the aid-major. See MAJOR.

Each battalion of foot, and regiment of horse, has an adjutant, who receives the orders every night from the brigade-major; which, after carrying them to the colonel, he delivers out to the serjeants.

When detachments are to be made, he gives the number to be furnished by each company, and assigns the hour and place of rendezvous. He also places the guards, receives and distributes the ammunition to the companies; and, by the major's orders, regulates the price of bread, beer, &c.

ADJUTANT is sometimes used by the French for an aid-du-camp. See AID-DU-CAMP.

ADJUTANTS-General, among the Jesuits, a select number of fathers, who reside with the general of that order: they have each a province, or country, assigned them, as England, Germany, &c. and their business is to inform the father-general of state occurrences in such countries.

ADJUTORIUM, among physicians, is used for a medicine prescribed along with another more efficacious one; and, particularly, for an external application, after the proper use of internal medicines.

ADJUTORIUM, in anatomy, a name sometimes given to the humerus, or shoulder-blade. See HUMERUS.

ADMEASUREMENT, in law, a writ for adjusting the shares of something to be divided. Thus,

ADMEASUREMENT of Dower takes place, when the widow of the deceased claims more as her dower than what of right belongs to her. And,

ADMEASUREMENT of Pasture may be obtained, when any of the persons who have right in a common pasture, puts more cattle to feed on it than he ought.

ADMINICLE, *adminiculum*, in our old law-books, is used for aid, help, or support.

ADMINICLE, in the French jurisprudence, signifies the beginning or first sketch of a proof.

ADMINICLES, among antiquarians, denote the attributes or ornaments wherewith Juno is represented on medals.

ADMINICULATOR, in church-history, an officer otherwise called advocate of the poor. See ADVOCATE.

ADMINISTRATION, in a political sense, denotes, or ought to denote, the attendance of the trustees of the people on public affairs; but, more particularly, administration is used for the executive part of the government, which is said to be good or bad, according as the laws are duly enforced, and justice done the subjects. See **GOVERNMENT**.

ADMINISTRATION, in law, the office of an administrator. See **ADMINISTRATOR**.

Whenever a man dies intestate, letters of administration are taken out in the prerogative court.

ADMINISTRATION is also used for the management of the affairs of a minor, lunatic, &c.

ADMINISTRATOR, in law, the person to whom the goods, effects, or estate of one who died intestate are entrusted; for which he is to be accountable, when required.

The bishop of the diocese where the party dies, is regularly to grant administration: but if the intestate has goods in different dioceses, he is to be accountable for them, when required.

The persons to whom administration is granted are a husband, wife, children, whether sons or daughters, the father or mother, brother or sisters, and in general the next of kin, as uncle, aunt, cousin; then to a creditor.

An action lies for and against an administrator, as for and against an executor; only that he is accountable no farther than to the value of the goods.

ADMINISTRATRIX, a female, or woman who acts as administrator. See **ADMINISTRATOR**.

ADMIRAL, *Admiralis*, or *Admirallus*, a great officer who superintends the naval armaments of a kingdom, and has the determination of all causes in the marine.

There has been great variety of opinions with regard to the origin and denomination of this important office; which seems to have been established in most countries lying near the sea. Some have borrowed it from the Greek, others from the Arabic, while a third sort, with more appearance of reason, derive both the title and dignity from the Saracens. But as no certain conclusions seem to have been hitherto deduced from these elaborate researches, and since it is not our province to give an historical or chronological detail of the difference of rank and power with which admirals have been invested in different nations, we shall decline to fatigue our readers with an enquiry so fruitless and foreign to our purpose; and instead thereof, present them with a real account of the office and duty of admirals at sea, as well as of the Lord high Admiral of England, the former of which seems to have been entirely neglected, probably for a very sufficient reason, by the gentlemen who have hitherto furnished us with these critical investigations.

Lord high ADMIRAL of England, styled in some ancient records, *capitaneus maritimarum*, an officer of great antiquity and trust, who has the entire management of the royal navy, and formerly had the decision of all maritime cases, civil and criminal; he judged of all things done at sea, or abroad by British mariners, and those with whom they might be connected; upon the sea-coasts, in all ports and havens, and upon all rivers below the first bridge from the sea. By him the inferior admirals, captains, and lieutenants are commissioned; all deputies for particular coasts appointed, and coroners to view dead bodies found on the sea-coast, or at sea: he also appoints the judges for his court of admiralty, and may imprison, &c. All ports and havens are *infra corpus comitatus*, and the lord admiral hath no jurisdiction of any thing done therein. Between high and low water mark the admiral and common law have jurisdiction alternately, one upon the land, and the other upon the water. The admiral hath likewise power to arrest ships in harbours, &c. and during the voyage every commanding officer, soldier, or other, are to observe the orders of the lord admiral on pain of death, or other punishment.

The lord admiral has power to arrest all British seamen, and detain them for the service of the state, after which they become immediately subject to military laws in case of desertion. To him belongs all penalties and amercements of all transgressions at sea, on the sea shore, in ports and havens, and all rivers, below the first bridge from the sea; the goods of pirates and felons condemned or enslaved; sea-wrecks, goods floating at sea, or cast ashore; also all great fishes, commonly called royal fishes, except whales and sturgeons: to which we may add a salary of 7000*l.* a year.

In the time of Edward I. and king John all causes of merchants and mariners, and things arising on the main sea, were tried before the lord admiral; by all which, and other laws, the power of the admiral is not only declared, but the original from whence it is derived, namely, from the legislative power of the parliament, and not from the single person of the king, or any other council whatever.

This office is indeed so great in point of trust, honour, and profit, that it has seldom been invested in any other than princes of the blood, or the most eminent persons among the nobility. For some years we have had no high admiral, the office being put in commission, or under the administration of the lords commissioners of the admiralty, who by statute have the same power and authority as the lord high admiral. When he embarks, the flag of the anchor and rope is immediately displayed.

ADMIRAL of the Fleet, the highest officer under the command of the lord high admiral: he is distinguished

tinguished by hoisting the union flag at the main-top-mast head. Admiral also implies the commander of any single fleet or squadron, or in general any officer whatsoever who carries his flag at the main-top-mast head.

The admiral or flag officer is to acquaint the secretary of the admiralty of all his proceedings relating to the service, for the information of the lord high admiral, or lords commissioners of the admiralty. It is his duty, when at sea, to arrange the ships under his command into lines or ranks of battle, as often as convenient, in order to exercise the officers and crew in the discipline of naval war; every ship being distinguished by a particular signal displayed on board of the admiral. He is often to visit the other ships of his squadron, and see the men mustered, that no supernumeraries may be borne on the books. He is to assist at all councils of war that relate to naval affairs, and to attend the lord high admiral on his return home, with an account of his expedition or voyage, and transmit a copy of his journal to the secretary of the admiralty. See **LINE**, **SIGNAL**.

Vice ADMIRAL, the officer next in rank and command to the admiral. He carries his flag at the fore-top-mast head.

Rear ADMIRAL, the officer next in rank and command to the vice. He carries a flag at the mizen-top-mast head.

There are at present in England, besides the admiral of the fleet, four admirals of the white squadron, and three of the blue; four vice admirals of the red, five of the white, and six of the blue squadron; four rear admirals of the red, five of the white, and five of the blue squadron; besides twenty-nine rear admirals that have carried no flag, superannuated, on half-pay.

Vice ADMIRAL, is also an officer appointed by the lords commissioners of the admiralty. There are several of these officers established in different parts of Great Britain, with judges and martials under them, for executing jurisdiction within their respective limits. Their decisions however, are not final, an appeal lying to the court of admiralty in London.

ADMIRAL, in natural history, is the name of a beautiful shell of the voluta kind, greatly admired by the curious.

There are four species of this shell distinguished by the names of grand-admiral, vice-admiral, orange-admiral, and extra-admiral. The first is extremely beautiful, of an elegant white enamel, variegated with bands of yellow, which, in some measure, represent the colours of the flags in ships of war. It is of a very curious shape, and finely turned about the head; but its distinguishing character is a denticulated line running along the center of the large yellow band; and this distinguishes

it from the vice-admiral, though the head of the latter is also less elegantly formed.

The orange-admiral has more yellow than any of the others, and the bands of the extra-admiral run into one another.

ADMIRALTY, the office of lord high-admiral, whether discharged by one single person, or by joint commissioners, called lords of the admiralty.

Court of ADMIRALTY is a sovereign court, held by the lord high-admiral, or lords of the admiralty, where cognizance is taken of all maritime affairs, whether civil or criminal; where they are tried by judge and jury: but in civil cases the manner is different, the decisions being all made according to the civil law.

ADMIRATION, in grammar, is a mark or character made use of to signify something that is wonderful, or worthy of admiration: it is expressed thus (!), and may be placed either at the end of the word that is exclamatory, or deferred to the end of a sentence. It seems however as if this distinction should be made, that when the exclamation is not detached from the other part of the sentence, it should be postponed to the end, as in the following lines:

See how the force of others prayers I try,
(Oh pious fraud of amorous charity !)

Where the exclamation is detached, it will be better, if placed immediately after it, as thus,
Jesus ! — and didst thou leave thy blest abode, &c.

But nothing is so vague and arbitrary as punctuation. See **PUNCTUATION**.

ADMISSION, *admissio*, among ecclesiastical writers, denotes the act of a bishop's admitting or allowing a clerk to be able, or qualified for serving a cure.

This is done after examination, by pronouncing the formula *admitte te babilen*. If any person presume to be admitted, who has not episcopal ordination, he shall forfeit 100*l*.

ADMITTENDO clerico, a writ granted to a person, who has recovered his right of presentation in the common pleas; by which the bishop, or metropolitan, is ordained to admit his clerk. See **ADMISSION**.

ADMITTENDO in socium, a writ associating certain persons, usually knights, and other gentlemen of the county, to the justices of assize already appointed.

ADMONITION, in church history, a part of discipline which consists chiefly in warning an offender of the irregularities he is guilty of, and advising him to mend his manners.

By the ancient canons, nine admonitions were required before excommunication. See **EXCOMMUNICATION**.

ADMONITIO *fustum*, among the Romans, a military punishment, not unlike our whipping, only that it was performed with vine branches.

ADMORTIZATION, in the feudal customs, the reducing the property of lands or tenements to mortmain. See **MORTMAIN**.

ADNATA, in anatomy, one of the tunics or coats of the eye; otherwise called conjunctiva and albuginea.

It is the same part with what is called the white of the eye, formed by the tendinous expansions of the muscles which move the eye. See **EYE**.

ADNATA, in botany, implies the increase which grows on the sides of bulbous roots, as lillies, tulips, narcissus's, pancratiums, &c. these off-sets will shew their blossoms in a much shorter time, than by propagation from seed.

ADNATA is also a term used for such things as grow upon animal or vegetable bodies, whether inseparable, as hair, wool, horns, &c. or accidental, as the few epistimal plants.

ADNOUN, in grammar, the same with adjective. See **ADJECTIVE**.

ADOLESCENCE, the flower of youth in the human species, commencing at infancy and terminating in manhood. This period of human life is commonly computed from fifteen to twenty-five years of age.

ADONAI, one of the names of God used in scripture. It properly signifies *my lords*.

ADONAI, in antiquity, were festivals kept in honour of Venus, and in memory of her beloved Adonis.

The Adonai lasted two days; on the first of which the images of Venus and Adonis were carried with great solemnity, in the manner of a funeral; the women following the statues, crying, tearing their hair, and beating their breasts. On the second they changed the mournings into joy, and sung his praises, as if Adonis had been again restored to life.

The Adonia were celebrated by the ancient Greeks, Egyptians, Syrians, Lycians, &c.

ADONIAS, a name given by the ancient botanists to the anemony, or wind flower, from a supposition that it owed its origin to the tears shed by Venus in lamenting the death of her beloved Adonis.

ADONIC, in ancient poetry, a kind of verse consisting of a dactyle and spondee.

This kind of verse has its name on account of its being originally used in the lamentations for Adonis. Its principal use however among the poets, is to serve as a conclusion to each strophe of Saphic verse.

ADONIS *flos*, in botany, a genus of plants whose leaves bear the resemblance of fennel. The flower is polyandrious and rosaceous, with many germina collected in one head: the common fort

in gardens is called pheasant's eye, from its similitude to the eye of a pheasant.

ADOPTIANI, in ecclesiastical history, a sect of heretics, who maintained that Christ, with respect to his human nature, was not the natural but the adoptive son of God.

ADOPTION, a solemn act, whereby one man makes another his heir; investing him with all the rights and privileges of a son.

ADOPTIVE, in a general sense, implies something adopted.

ADOPTIVE Arms, in heraldry, are those enjoyed by the concession of another, which the adopter is obliged to marshal with his own, as being the condition of some honour or estate left him.

ADORATION, the act of worshipping the divine Being.

This ceremony was differently performed by different people. Among the Jews it consisted in kissing the hands, bowing, kneeling, and even prostration. Among the Romans it was performed with the head veiled, or covered, the devotee applying his right hand to his lips, the fore-finger resting upon the thumb, which was erect; and then bowing, he turned himself round from left to right. The Gauls, on the contrary, thought it more religious to turn from right to left: and the Greeks to worship with their heads uncovered. The Christians follow the Grecian rather than the Roman mode, by uncovering their heads when they perform any kind of adoration.

Divines speak of many kinds of adoration; as supreme adoration, or that which is paid immediately to God; subordinate adoration, or that rendered to inferior beings; absolute adoration, or that paid to a being on account of its own perfections: this is opposed to relative adoration, or that paid to an object as belonging to, or representing another.

ADORATION is also used in a civil sense, for any extraordinary homage, or respect paid by one man to another.

The Persians adored their kings by falling prostrate before them, striking the earth with their foreheads, and kissing the ground. This was a piece of servility which Conon, a nobleman of Athens, refused to comply with when introduced to Artaxerxes; neither would the philosopher Calisthenes perform it to Alexander the Great, as judging it at once impious and unlawful.

The Roman emperors were adored, by bowing or kneeling at their feet, laying hold of their purple robe, and immediately withdrawing the hand and kissing it.

ADORATION is more commonly used to signify the ceremony of paying homage to the pope, by kissing his feet; which not only the people, but the greatest prelates, and even princes themselves, of the Romish religion, make no scruple of performing.

ADORATION is still more particularly used for one of the methods used in electing a new pope; when the cardinals, instead of proceeding in the usual way, unanimously fall down and adore one of their own number. Adoration is the last ceremony of a regular election, but here it is the election itself, or rather supercedes it.

Perpetual ADORATION, in the church of Rome, a kind of religious society, frequent in the popish countries; it consists of a number of devout persons, who by dividing themselves into three bodies, and regularly relieving one another at stated hours, keep constantly praying before the eucharist day and night.

ADOSSEE, in heraldry, a term used for two rampant lions placed back to back.

It is also used to signify any other figures, as axes, keys, &c. placed with their heads facing different ways.

ADOXA, in botany, the tuberose moschatel, a low plant of a perfume smell, growing in several woods in England: its leaves are like those of the bulbous fumitory, and the flowers monopetalous. It is called in some places musk crowfoot.

AD QUOD DAMNUM, in law, a writ which ought to be issued before the king grants certain liberties, as a fair, market, or the like; ordering the sheriff to enquire what damage the country is likely to suffer by a grant of that kind. The same writ is also issued, for making a similar enquiry with respect to lands granted to religious houses, or corporations; for turning and changing of highways, &c.

ADSTRICTION, among physicians, implies too great a rigidity and closeness in the emunctories of the body, particularly the pores of the skin. They also sometimes use it to signify the styptic or astringent quality of medicines.

AD TERMINUM *qui præterit*, in law, a writ of entry that lies for the lessor or his heirs, if after the expiration of a term for life or years, granted by lease, the tenant or other occupier of the lands, &c. withholds the same from such lessor.

ADVANCE, in the mercantile stile, denotes money paid before goods are delivered, work done, or business performed.

ADVANCE-Fosse, in fortification, a ditch thrown round the esplanade or glacis of a place, to prevent its being surprized by the besiegers.

The ditch sometimes made in that part of the lines or retrenchments nearest the enemy, to prevent him from attacking them, is also called the advance-fosse. See **RETRENCHMENT**, and **LINE of Circumvallation**.

The advance-fosse should always be full of water, otherwise it will serve the enemy for a covering from the fire of the place, if he becomes master of the fosse; beyond the advance-fosse it

is usual to construct lunettes, redoubts, &c. See **LUNETTE**, and **REDOUBT**.

ADVANCED-guard, or *Van-guard*, in the art of war, denotes the first line or division of any army, ranged, or marching in order of battle; or it is that part which is next the enemy, and marches first towards them. See **ARMY**.

ADVANCED-guard is more particularly used for a small party of horse stationed before the main-guard. See **GUARD**.

ADUAR, in the Arabian and Moorish customs, a kind of ambulatory village, consisting of tents; which these people remove from one place to another, as suits their convenience.

ADVENT, in the calendar, denotes the time immediately preceding Christmas. It includes four Sundays, or weeks, which begin either on St. Andrew's day, or on the Sunday before or after it.

The term advent, *adventus*, properly signifies the approach or coming on of the feast of the nativity. See the article **NATIVITY**.

During advent, and the end of the octaves of epiphany, the solemnizing of marriage is forbid, without a special licence. See **MARRIAGE**.

ADVENTITIOUS, an appellation given to whatever accrues to a person or thing from without. Such are spary incrustations upon wood, &c.

ADVENTITIOUS, among civilians, denotes all such goods as are acquired accidentally, or by the liberality of a stranger, &c.

ADVENTITIOUS Fossils, the same with extraneous or foreign ones, found imbedded in other fossils: such as shells, bones, &c. in stone.

Bill of ADVENTURE, among merchants, a writing signed by a merchant, testifying that the goods mentioned in it to be shipped on board a certain vessel belong to another person, who is to run all hazards; the merchant only obliging himself to account to him for the produce of them, be that what it will.

ADVERB, *adverbium*, a term in grammar, made use of to modify the action which the verb signifies, and for that reason it is placed near the verb, according to its derivation, which is *ad* and *verbum*; not but that it is sometimes joined to adjectives, participles, nay and even substantives themselves, as, *He is truly king*.

Adverbs, though very numerous, may be reduced to the following classes: adverbs of time, as *when*; of place, as *where*; of quantity, as *how much*; of quality, as *wisely*; of manner, as *swiftly*; of interrogation, as *why*; of affirmation, as *yes*; of negation, as *no*; of diminution, as *almost*; of doubt, as *perhaps*; of exception, as *only*; with some adjectives, which in Latin, French, &c. are used adverbially, as, *transversatuentibus hircis*, for *transversè*; and, *il chante juste*, for *justement*.

ADVERSARIA, among the ancients, was a book of accounts, resembling in some measure our day-book, or journal. But the term is at present used by men of letters, to signify a common-place book, wherein they enter every thing that occurs to them worthy of notice.

ADVICE, or *Letter of Advice*, a letter missive, by which a merchant, or banker, informs his correspondent, that he has drawn a bill of exchange upon him, sent him a quantity of merchandize, or that his debtor's affairs are in a bad state.

If the letter of advice respects a bill of exchange, the name of the person in whose favour it was drawn, the date, value of the bill, and time of payment should be mentioned; for without such a letter of advice, it is very allowable for the person on whom the bill is drawn, to refuse both acceptance and payment.

ADULTERATION, in a general sense, implies the act of debasing by an improper mixture something that was before pure and genuine. Thus the adulteration of coin implies, the using a greater proportion of alloy than is appointed by the standard: and the adulteration of a medicine signifies the using ingredients of less virtue and efficacy in the composition, than those ordered in the recipe.

ADULTERY, the crime of married persons, whether husband or wife, who, in violation of their marriage vow, have carnal commerce with another besides the person to whom their faith has been plighted.

ADULTERY, in the scripture language, is also used to signify idolatry, or the forsaking the worship of the true God for that of an idol.

ADVOCATE, among the ancient Romans, implied a person who undertook the defence of causes, which he pleaded much in the same manner as our barristers do at present.

The term is still used in countries where the civil law obtains. In Scotland there is a college of advocates, consisting of one hundred and eighty members, appointed to plead in all actions before the lords of sessions. In France there are two kinds of advocates, one of which plead in all causes, and the other give their opinions.

Lord Advocate, one of the officers of state in Scotland, who pleads in all cases of the crown, or where the king is concerned.

ADVOCATE, among ecclesiastical writers, implies a person who undertakes the defence of a church, monastery, &c.

ADVOCATION, among civilians, signifies the act of calling another to assist us in pleading some cause.

Letters of Advocation, in the law of Scotland, implies a writ issued by the lords of session, advocating, or calling, a cause from an inferior judge to themselves.

ADVOWEE, in law, signifies the patron of a church, or the person who has a right to present to a benefice.

ADVOWSON, in law, implies the right of patronage, or presenting to a vacant benefice.

ADUSTION, among physicians, implies an inflammation of the parts about the brain and its membranes, attended with a hollowness of the fuciput and eyes, a pale colour, and dryness of the body.

ADYTUM, *adusor*, in pagan antiquity, the most retired and sacred place of their temples, into which none but the priests were allowed to enter.

The term is purely Greek, signifying inaccessible.

The adytum of the heathens answered to the *sanctum sanctorum* of the Jews, and was the place from whence they delivered oracles.

ADZE, a kind of ax, otherwise called addice. See the article **ADDICE**.

AE, or **Æ**, among grammarians, a diphthong, or double vowel, compounded of A and E.

The orthography of this diphthong is far from being fixed, the simple E frequently supplying its place. When, therefore, an article cannot be found under **Æ**, the reader is to look for it under E: though the references, for the most part, will be a faithful guide in cases of this nature.

ÆACEA, in Grecian antiquity, solemn festivals and games celebrated at **Ægina**, in honour of **Æacus**; who, on account of his justice upon earth, was thought to have been appointed one of the judges in hell.

ÆDILE, *ædilis*, in Roman antiquity, a magistrate whose chief business was to superintend buildings of all kinds, but more especially public ones, as temples, aqueducts, bridges, &c.

To the ædiles likewise belonged the care of the highways, public places, weights, and measures, &c. They also fixed the prices of provisions, took cognizance of debauches, punished lewd women, and such persons as frequented gaming houses. The custody of the plebeians, or orders of the people, were likewise committed to them. They had the inspection of comedies, and other pieces of wit; and were obliged to exhibit magnificent games to the people, at their own expence, whereby many of them were ruined.

At first the ædiles were only two in number, and chosen from among the common people; but these being unable to support the expence of the public shews, two more were created out of the patrician order; these last took upon themselves all the charges of the games, and were called *ædiles curules*, or *maiores*; as the two plebeians were denominated *minores*.

Julius Cæsar, in order to ease these four, created two

two others, who were called *ædiles cereales*, as having the inspection of all manner of grain committed to their care.

There were also *ædiles* in the municipal cities, who had much the same authority as those in Rome.

ÆDILITIAN *edict*, *ædilitium edictum*, among the Romans, was particularly used for the *ædile's* sentence, allowing redress to the purchaser of a beast, or slave, that had been imposed on.

ÆGAGROPILA, or *ÆGAGROPHILUS*, *αἰγάροφιλος*, in natural history, a ball composed of a substance resembling hair, generated in the stomach of the chamois-goat.

It is a kind of bezoar, called *bezoar germanicum*, and is possessed of no medicinal virtue, no more than the balls of the same kind formed in the stomachs of cows, hogs, &c. See *BEZOAR*.

ÆGILOPS, *Αἰγίλας*, among physicians, an abscess in the corner of the eye, next the nose; or, according to Heister, a small tumour caused by an inflammation or abscess, which in time, by the acrimony of its purulent matter, erodes the external skin, lacrymal ducts, and fat round the ball of the eye; nay, sometimes it renders the neighbouring bones carious to a dangerous degree.

As to the method of treatment, the surgeon is first to endeavour to disperse the tumour, by moistening it several times a day with spirit of vitriol; but if he finds this impracticable, he is to forward the suppuration as much as possible, lest an obstinate fistula, or worse consequences, should be the effects of too long delay. For this purpose, a plaister of diachylon with the gums, or emollient cataplasms may be used.

When fully ripe, the tumour is to be laid open with a lancet or scalpel, and the ulcer cleansed and healed in the ordinary way. See *ULCER*.

ÆGIPAN, in heathen mythology, a denomination given to the god Pan, by reason he was represented with the horns, legs, feet, &c. of a goat.

ÆGIS, in heathen mythology, is particularly used for the shield or cuirass of Jupiter and Pallas.

Ægis is derived from *αἰς*, *αἰγός*, a she-goat; Jupiter having covered his shield with the skin of Amalthea, the goat that suckled him. Afterwards making a present of the buckler to Minerva, this goddess fixed the head of Medusa on the middle of it, which, by that means, became capable of turning all those into stone who looked at it.

ÆGIUCHUS, in heathen mythology, a surname of Jupiter, given him on account of his having been suckled by a goat.

ÆGYPTIACUM, in pharmacy, the name of several detergent ointments, used for eating off rotten flesh, and cleansing foul ulcers.

ÆNIGMA, *αἰνίγμα*, denotes any dark saying or question, wherein some well known thing is concealed under obscure language.

The parable, gryphus, and rebus, are by some

accounted three species, or branches of *ænigma*. See *PARABLE*, *GRYPHUS*, and *REBUS*.

ÆOLIC dialect, among grammarians, one of the five dialects of the Greek tongue, agreeing in most things with the Doric dialect. See *DORIC*.

ÆOLIC digamma. See *DIGAMMA*.

ÆOLIC verse, in prosody, a kind of verse, consisting of an iambus, or spondee, then of two anapaests, separated by a long syllable, and lastly, of another syllable. Such is,

O stelliferi conditor orbis.

ÆOLIPILE, in hydraulics, an instrument consisting of a hollow metalline ball, with a small pipe or neck screwed thereto, which being filled with water, and exposed to the fire, produces a strong blast of wind.

This instrument the mechanical and experimental philosophers chiefly make use of, to account for the natural cause and generation of winds, and some have used this machine to measure the gravity and rarefaction of the air, but without success, as there are many objections and difficulties which it is liable to. Others have supposed that if the *æolipile* was fixed to some sonorous instrument, as a trumpet or a horn, it might produce music, or with proper additions be made to represent the fluctuating and playing up and down of the stream of a fountain; likewise being placed before the fire, to serve as a pair of bellows, when an intense heat is required; but these suppositions are only theory, and not capable of being reduced to practice, for experience shews us that instead of the blast kindling the fire it totally extinguishes, or puts it out. However, the *æolipile* being properly constructed, it may with some success, we think, be applied to cure smoking chimnies, and without great expence; for being filled with water, and hung properly in the funnel of the chimney, the blast which will quickly ensue from the heat of the fire, will drive up the loitering smoke, and cause a strong draught. See *WIND*, *HEAT*, *WATER*, *AIR*, and *RAREFACTION*.

ÆOLUS, in the heathen theology, the god of the winds, painted with swollen blubber cheeks, like one who with main force endeavours to blow a blast; also with two small wings upon his shoulders, and a fiery high-coloured countenance.

<i>EQUATION</i> ,	} See	<i>EQUATION</i> .

ÆRA,

ÆRA, in chronology, a series of years, commencing from a certain fixed point of time, called epocha: thus, we say the Christian æra, that is, the number of years elapsed since the birth of Christ.

The generality of authors, however, use the terms æra and epocha in a synonymous sense, or for the point of time from which the computation commences, making no other difference between them, except that the former is chiefly used by the vulgar, and the latter by chronologists. See EPOCHA.

AERIAL, in a general sense, denotes something partaking of the nature of air: thus we say, an aerial substance, aerial particles, &c.

AERIAL Perspective, is that which represents bodies diminished and weakened in proportion to their distance from the eye, and has chiefly to do with the colours of objects, whose lustre and force is diminished in proportion to the distance of the object you are to represent; for the longer the column of air that any body is seen through, so much the fainter do the rays emitted from it, appear to the eye. See PERSPECTIVE.

AERIANS, *Aeriani*, in church history, the name of certain sectaries of the fourth century, who were so called from Aerius, a priest of Armenia, who was their chief. These Arians had pretty much the same notions, with respect to the Trinity, that the Arians had; but they entertained besides some tenets that were peculiar to themselves. Aerius was dissatisfied that Eustathius, his former companion, should succeed to a bishopric, for which he had been candidate himself; and therefore defamed the order of bishops, as an encroachment upon the priesthood. He looked upon all the facts of the church to be merely superstitious, and affirmed that even the passover itself should not be observed; he admitted none into his sect, but those who lived in continence, and condemned marriage as unlawful.

AEROGRAPHY signifies a description of the air, especially of its dimensions, and other most obvious properties; in which sense, it differs but little from

AEROLOGY, which is a scientific account of the nature and less obvious properties of air. See AIR and ATMOSPHERE.

AEROMANCY, *Aeromantia*, a species of divination performed by means of air, winds, &c.

AEROMANCY is also used for the art of foretelling the various changes of the air and weather, by means of barometers, hygrometers, &c. See BAROMETER, &c.

AEROMETRY, the science of measuring the air, its powers and properties; the term, at present, is not much in use, for this part of natural philosophy is commonly called pneumatics. See PNEUMATICS.

ÆSCHYNOMENE, in botany, a genus of plants, that bears a papilionaceous flower, and its leaves contract by the touch; whence it has been called the bastard sensitive plant. Botanists enumerate five sorts, which are all natives of the warmer climates.

ÆSCULAPIUS's Serpent, *Æsculapii anguis*, in zoology, a harmless kind of serpent, otherwise called paræa. See PARÆA.

ÆSCULUS, in botany. See HORSE-CHESNUT.

ÆTHER, *Æther*, in physiology, an exceeding fine, thin, subtle fluid, concerning which philosophers are greatly divided; however, the sentiments of Sir Isaac Newton, which are most received, are as follows:

1. He supposes that an æthereal substance is diffused through all places, and that it is capable of contraction and dilatation, strongly elastic, and much like air in all respects, but much more subtle.

2. He supposes that this æther pervades all gross bodies, but yet so as to stand rarer in their pores, than in free spaces, and so much the rarer as their pores are less: that it is the cause why light incident on those bodies, is refracted towards the perpendicular. See LIGHT and REFRACTION. Why two well polished metals cohere in a receiver exhausted of air. See COHESION. Why mercury stands sometimes up to the top of a glass pipe, though much higher than 30 inches, and one of the chief causes why the parts of all bodies cohere; also the cause of filtration, of the rising of water in small glass pipes, above the surface of the stagnated water they are dipped in, for he suspects the æther may stand rarer, not only in the insensible pores of bodies, but even in the very sensible cavities of these pipes. See CAPILLARY TUBE. And the same principle may cause menstrua to pervade with violence the pores of bodies they dissolve, the surrounding æther as well as the atmosphere pressing them together.

3. He supposes the rarer æther within bodies, and the denser without them, not to be terminated in a mathematical superficies, but to grow gradually into one another, the external æther beginning to grow rarer, and the internal to grow denser, at some little distance from the superficies of the body, and running through all degrees of density in the intermediate spaces; and that this may be the cause why light, in Grimaldi's experiment, passing by the edge of a knife, or other opaque body, is turned aside, and as it were refracted, and by that refraction makes several colours.

Let ABCD, (Plate VI. fig. 1.) be a dense body whether opaque or transparent; EFGH, the outside of the uniform æther which is within it; IKLM, the inside of the uniform æther which is without it, and conceive the æther which is between EFGH and IKLM to run through all

R

intermediate

intermediate degrees of density, between that of the two uniform æthers on either side. This being supposed, the rays of the sun SB, SK, which pass by the edge of this body between B and K, ought in their passage through the unequally dense æther there, to receive a ply from the denser æther, which is on that side towards K; and that the more, by how much they pass nearer to the body, and thereby be scattered through the space PQRS T, as by experience they are found to be. Now the space between the limits EFGH and IKLM, he calls the space of the æther's graduated rarity.

4. When two bodies moving towards one another come near together, he supposes the æther between them to grow rarer than before, and the spaces of its graduated rarity to extend further from the superficies of the bodies towards one another, and this by reason that the æther cannot move and play up and down so freely in the straight passage between the bodies as it could before they came so near together. Thus, if the space of the æther's graduated rarity reach from the body ABCDEF (*fig. 2.*) only to the distance GHL MRS, when no other body is near it, yet may it reach farther, as to IK, when another body NOPQ approaches; and as the other body approaches more and more, he supposes the æther between them will grow rarer and rarer.—Note, He has so described those suppositions, as if he thought the spaces of graduated æther had precise limits, as is expressed at IKLM in the first figure, and at GMR S in the second, for thus he thought he could better express himself: but he did not think they have such precise limits, but rather decay insensibly, and in so decaying, extend to a much greater distance than can easily be believed, or need be supposed.

5. Now, from the fourth supposition it follows, that if two bodies approaching one another, come so near together as to make the æther between them begin to rarify, they will have a reluctance from being brought nearer together, and an endeavour to recede from one another; which reluctance and endeavour will increase as they come nearer together, because thereby they cause the interjacent æther to rarefy more and more; but at length, when they come so near together, that the excess of pressure of the external æther which surround the bodies, above that of the rarefied æther which is between them, is so great, as to overcome the reluctance which the bodies have from being brought together, then will that excess of pressure drive them with violence together, and make them adhere strongly to one another, as was said in the second supposition.

For instance, (*Plate IV. fig. 2.*) when the bodies ED and NP are so near together, that the spaces of the æther's graduated rarity begin to reach one

another, and meet in the line IK, the æther between them will have suffered much rarefaction, which rarefaction requires much force; that is, much pressing of the bodies together; and the endeavours which the æther between them has to return to its former state of condensation, will cause the bodies to have an endeavour to recede from one another. But on the other hand, to counterpoise this endeavour, there will not yet be any excess of density of the æther which surrounds the bodies, above that of the æther which is between them at the line IK. But if the bodies come nearer together, so as to make the æther in the midway line IK, grow rarer than the surrounding æther, there will arise from the excess of density of the surrounding æther, a compresure of the bodies toward one another, which when by the near approach of the bodies, it becomes so great as to overcome the aforesaid endeavour the bodies have to recede from one another, they will then go towards one another, and adhere together; and on the contrary, if any power force them asunder to that distance, where the endeavour to recede begins to overcome the endeavour to accede, they will again leap from one another. Hence, he conceives, it is chiefly that a fly walks on water without wetting her feet, and consequently, without touching the water; that two polished pieces of glass are not without pressure brought to contact, no, not though one be plane, the other a little convex; that the particles of dust cannot be made to cohere, as they would do if they did but fully touch; that the particles of tinging substances, and salts dissolved in water, do not of their own accord concrete and fall to the bottom, but diffuse themselves all over the liquor, and expand still more if you add more liquor to them. Also, that the particles of vapours, exhalations, and air, do stand at a distance from one another, and endeavour to recede as far from one another as the pressure of the incumbent atmosphere will let them: for he conceives the confused mass of vapours, air, and exhalations, which we call the atmosphere, to be nothing else but the particles of all sorts of bodies of which the earth consists separated from one another, and kept at a distance by the same principle.

He likewise supposes æther to consist of parts differing from one another in subtilty by indefinite degrees; that in the pores of bodies there is less of the grosser æther in proportion to the finer than in open spaces, and consequently, that in the great body of the earth, there is much less of the grosser æther in proportion to the finer than in the regions of the air; and that yet the grosser æther in the air affects the upper regions of the earth, and the finer æther in the earth the lower regions of the air, in such a manner, that from the top of the air to the surface of the earth,

and

and again from the surface of the earth to the center thereof, the æther is insensibly finer and finer. Imagine now any body suspended in the air, or lying on the earth, and the æther being by the hypothesis, grosser in the pores which are in the upper parts of the body, than those which are in the lower parts of the body, and that the grosser æther being less apt to be lodged in those pores, than the finer æther below, it will endeavour to get out and give way to the finer æther below, which cannot be without the bodies depending to make room above for it to go out into. See GRAVITY.

The above doctrine of the æther is part of what was drawn up by Sir Isaac Newton for the use of Mr. Boyle; his further thoughts on the same subject will be found in the following Queries, which he inserted many years after among others, in his excellent book of Optics.

Qu. 16. When a man in the dark presses either corner of his eye with his finger, he will see a circle of colours like those in a peacock's tail. If the eye and the finger remain quiet, these colours vanish in a second minute of time; but if the finger be moved with a quivering motion they appear again. Do not these colours arise from such motions excited in the bottom of the eye, by the pressure and motion of the finger, as at other times are excited there by light causing vision? And do not the motions once excited continue about a second of time before they cease? And when a man by a stroke upon his eye sees a flash of light, are not the like motions excited in the retina by the stroke? And when a coal of fire moving nimbly in the circumference of a circle, makes the whole circumference appear like a circle of fire, is it not because the motions excited in the bottom of the eye by the rays of light, are of a lasting nature, and continue till the coal of fire in going round returns to its former place? And considering the lastingness of the motions excited in the bottom of the eye by light, are they not of a vibrating nature?

Qu. 17. If a stone be thrown into stagnating water, the waves excited thereby continue some time to arise in the place where the stone fell into the water, and are propagated from thence in concentric circles upon the surface of the water to great distances. And the vibrations or tremors excited in the air by percussion, continue a little time to move from the place of percussion in concentric spheres to great distances. And in like manner, when a ray of light falls upon the surface of any pellucid body, and is there refracted or reflected; may not waves of vibrations or tremors be thereby excited on the refracting or reflecting medium at the point of incidence, and continue to arise there, and to be propagated from thence as long as they continue to arise, and be propagated when they are

excited in the bottom of the eye by the pressure or motion of the finger, or from the light which comes from the coal of fire in the experiments above mentioned? And these vibrations propagated from the point of incidence to great indistances? And do they not overtake the rays of light, and by overtaking them successively, do they not put them into fits of easy reflection and easy transmission described above? For if the rays endeavour to recede from the densest part of the vibration, they may be alternately accelerated and retarded by the vibrations overtaking them.

Qu. 18. If in two large tall cylindrical vessels of glass inverted, two little thermometers be suspended so as not to touch the vessels, and the air be drawn out of one of these vessels, and these vessels thus prepared be carried out of a cold place into a warm one; the thermometer *in vacuo* will grow warm as much, and almost as soon, as the thermometer which is not *in vacuo*. And when the vessels are carried back into the cold place, the thermometer *in vacuo* will grow cold almost as soon as the other thermometer. Is not the heat of the warm room, conveyed through the vacuum by the vibrations, of a much subtler medium than air, which after the air was drawn out remained in the vacuum? And is not this medium the same with that medium by which light is refracted and reflected, and by whose vibrations light communicates heat to bodies, and is put into fits of easy reflexion and easy transmission? And do not the vibrations of this medium in hot bodies, contribute to the intenseness and duration of the heat? And do not hot bodies communicate their heat to contiguous cold ones, by the vibrations of this medium propagated from them into the cold ones? And is not this medium exceedingly more rare and subtle than the air, and exceedingly more elastic and active? And doth it not readily pervade all bodies? And is it not, by its elastic force, expanded through all the heavens? See HEAT.

Qu. 19. Doth not the refraction of light proceeded from the different density of this æthereal medium in different places, the light receding always from the denser parts of the medium? And is not the density of it greater in free and open spaces void of air and other grosser bodies, than within the pores of water, glass, crystal, gems, and other compact bodies? For when light passes through glass or crystal, and falling very obliquely upon the farther surface thereof is totally reflected, the total reflection ought to proceed rather from the density and vigour of the medium without and beyond the glass, than from the rarity and weakness thereof.

Qu. 20. Doth not this æthereal medium in passing out of water, glass, crystal, and other compact and dense bodies, into empty spaces, grow denser and denser by degrees, and by that means refract

refract the rays of light, not in a point, but by bending them gradually in curve lines? And doth not the gradual condensation of this medium extend to some distance from the bodies, and thereby cause the inflections of the rays of light, which pass by the edges of dense bodies, at some distance from the bodies. See INFLECTION, REFLECTION, and REFRACTION.

Qu. 21. Is not this medium much rarer within the dense bodies of the sun, stars, planets and comets, than in the empty celestial spaces between them? And in passing from them to greater distances, doth it not grow denser and denser perpetually, and thereby cause the gravity of those great bodies towards one another, and of their parts towards the bodies; every body endeavouring to go from the denser parts of the medium towards the rarer? For if this medium be rarer within the sun's body than at its surface, and rarer there than at the hundredth part of an inch from its body, and rarer there than at the fifteenth part of an inch from its body, and rarer there than at the orb of Saturn; he sees no reason why the increase of density should stop any where, and not rather be continued through all distances from the Sun to Saturn, and beyond. And though this increase of density may be exceeding slow, yet if the elastic force of this medium be exceeding great, it may suffice to impel bodies from the denser parts of the medium towards the rarer, with all that power which we call gravity. And that the elastic force of this medium is exceeding great, may be gathered from the swiftness of its vibrations. Sounds move about 1140 English feet in a second of time, and in seven or eight minutes of time they move above one hundred English miles. Light moves from the Sun to us in about seven or eight minutes of time, which distance is about 70000000 of English miles, supposing the horizontal parallax of the Sun to be twelve seconds. And the vibrations or pulses of this medium, that they may cause the alternate fits of easy transmission and easy reflexion, must be swifter than light, and by consequence above 700000 times swifter than sounds. And therefore the elastic force of this medium, in proportion to its density, must be above 700000×700000 (that is, above 490000000000) times greater than the elastic force of the air is in proportion to its density. For the velocities of the pulses of elastic mediums, are in a subduplicate ratio of the elasticities and the rarities of the mediums taken together.

As attraction is stronger in small magnets than in great ones, in proportion to their bulk; and gravity is greater in the surfaces of small planets than in those of great ones, in proportion to their bulk; and small bodies are agitated much more by electric attraction, than great ones: so the smallness of the rays of light may contribute very

much to the power of the agent by which they are refracted. And so if any one should suppose that æther, like our air, may contain particles which endeavour to recede from one another (for he owns he does not know what this æther is) and that its particles are exceedingly smaller than those of air, or even than those of light; the exceeding smallness of its particles may contribute to the greatness of the force by which those particles may recede from one another, and thereby make that medium exceedingly more rare and elastic than air, and by consequence exceedingly less able to resist the motions of projectiles, and exceedingly less able to press upon gross bodies, by endeavouring to expand itself.

Qu. 22. May not planets and comets, and all gross bodies, perform their motions more freely, and with less resistance, in this ætherial medium, than in any fluid which fills all space adequately without leaving any pores, and by consequence is much denser than quicksilver or gold? And may not its resistance be so small, as to be inconsiderable? For instance, if this æther should be supposed 700000 times more elastic than our air, and above 700000 times more rare; its resistance would be above 600000000 times less than that of water. And so small a resistance would scarce make any sensible alteration in the motions of the planets in ten thousand years. If any one would ask, how a medium can be so rare? let him tell us how the air, in the upper parts of the atmosphere, can be above a hundred thousand times rarer than gold. Let him also tell us, how an electric body can, by friction, emit an exhalation so rare and subtle, and yet so potent, as by its emission to cause no sensible diminution of the weight of the electric body, and to be expanded through a sphere, whose diameter is above two feet; and yet to be able to agitate, and carry up leaf-copper, or leaf-gold, at the distance of above a foot from the electric body? And how the effluvia of a magnet can be so rare and subtle, as to pass through a plate of glass without any resistance or diminution of their force; and yet so potent, as to turn a magnetic needle beyond the glass?

Is not vision performed chiefly by the vibrations of this medium, excited in the bottom of the eye by the rays of light, and propagated through the solid, pellucid, and uniform capillamenta of the optic nerves into the place of sensation? And is not hearing performed by the vibrations either of this or some other medium, excited in the auditory nerves by the tremors of the air, and propagated through the solid, pellucid, and uniform capillamenta of those nerves into the place of sensation? And so of the other senses.

Qu. 24. Is not animal motion performed by the vibrations of this medium, excited in the brain by the power of the will, and propagated from thence through

through the solid, pellucid, and uniform capillamenta of the nerves into the muscles, for contracting and dilating them? Supposing that the capillaments of the nerves are each of them solid and uniform, that the vibrating motion of the æthereal medium may be propagated along them from one end to the other, uniformly and without interruption: for obstructions in the nerves create palsies. And that they may be sufficiently uniform, he supposes them to be pellucid, when viewed singly, though the reflections in their cylindrical surfaces, may make the whole nerve composed of many capillamenta appear opaque and white: for opacity arises from reflecting surfaces, such as may disturb and interrupt the motion of this medium.

ÆTHER, in chemistry, an extremely penetrating spirit, made by distilling spirit of wine with oil of vitriol, and then precipitating the sulphureous gas with an alkali.

Concentrated oil of vitriol being dropt by degrees into an equal quantity, or five or six times its quantity, of highly rectified spirit of wine, the liquor becomes first yellow and then reddish, and exhales an agreeable, diffusive, penetrating smell, which if freely taken in with the breath affects the lungs: the taste of the liquor is considerably acid.

On digesting the mixture for some days, and then committing it to distillation in a retort with a very gentle warmth, there arises a subtle spirit, more fragrant and penetrating in smell than the undistilled liquor, very volatile, inflammable, in taste not at all acid, but of the aromatic kind. This is the dulcified spirit of vitriol. It comes over in thin invisible vapours, which condense upon the sides of the recipient in straight striæ.

This spirit is succeeded by one of a different kind, which, being caught in a separate receiver, is found to be sensibly acid, and of a pungent suffocating smell, like the fumes of burning brimstone. Along with it comes over a small quantity of oil; which sometimes proves colourless, and swims on the sulphureous liquor, and sometimes appears yellowish or greenish, and sinks to the bottom, according as the vinous spirit in the mixture was in large or in small proportion.

The dulcified spirit also has frequently some slight acidity, sufficient to alter the fine green tincture, which in its perfect state it extracts from the leaves of plants. It is purified or rectified from this redundant acid, by mixing it with a weak solution of fixed alkaline salt, and distilling it over a second time: for every pint of the spirit, may be taken a solution of a dram of alkali in a pint of water.

If the spirit, thus rectified, be mingled again with an equal quantity of a like alkaline solution, the mixture shaken together, appears milky: on standing for a little time, there arises to the sur-

face an extremely subtle fluid, called by the chemists æther, or æthereal spirit of wine. A considerable quantity of dulcified spirit may still be separated from the remaining liquor by distillation; and this spirit, mixed with fresh alkaline solution, affords more æther.

The æther is the lightest, most volatile, and most inflammable of all known liquors. It swims on the most highly rectified spirit of wine, being lighter than that spirit in the proportion nearly of 0,730 to 0,830. Dropt on the warm hand, it almost exhales, diffusing a penetrating fragrance, and leaving no moisture behind. On the approach of a candle it takes fire, and goes off in a flash like lightning. It does not mingle with water, with acid, or with alkaline liquors; but dissolves some unctuous and resinous bodies. Among metallic substances, it discovers a remarkable attraction to gold, but seems to have no effect on any of the others: mixed with a solution of gold made in acids, it imbibes the gold from the acid, carries it to the surface, and keeps it there dissolved into a yellow liquor; hence its use for discovering gold in liquids.

The only person we know of who has given any plausible theory of the production of this subtle fluid, is Mr. Macquer. Spirit of wine consists chiefly of an oil, exquisitely attenuated by fermentation, and intimately combined with water. According to Mr. Macquer, the æther is no other than this subtilized oil, extricated by the vitriolic acid; which acid, having a strong affinity or attraction to water, absorbs the watery element of the spirit, and thus sets the oily one at liberty.

ÆTHERIAL, something that participates of the nature of æther. See **ÆTHER**.

ÆTHERIAL OIL, among chemists, a subtle essential oil, approaching to the nature of spirits. See the article **OIL**.

ÆTHIOPS, or *Æthiops Mineral*, a preparation of mercury, made by rubbing in a marble or glass mortar, equal quantities of quick-silver and flowers of sulphur, till the mercury wholly disappears, and there remains a fine deep black powder; from whence it has got the name of *Æthiops*.

This is esteemed one of the safest preparations of mercury, and is much used against cutaneous foulnesses, in scrophulous cases, in remains of venereal disorders, and even in the gout and rheumatism. In scorbutic cases scarce any medicine exceeds it; and it has been long known as a remedy against worms. Its dose is from a scruple to a dram or two.

ÆTHIOPS Albus, a preparation of mercury, which is made by rubbing quick-silver with a double quantity of crabs-eyes, or of sugar-candy, till it is extinguished.

ÆTHIOPS of Dr. Plummer, a medicine prepared by levigating sulphur auratum antimonii, with an equal

equal quantity of calomel: it is said to be good in venereal and other cutaneous disorders.

AETIANS, the followers of Aetius, known by the name of the Impious, a native of Syria, born in the fourth century: he was first a menial servant, then a goldsmith, afterwards a quack-doctor, and last of all a priest. He was a subtle sophist, and a noisy disputant; and the doctrine of Arius making at that time a great bustle in the Christian world, he embraced it, and became one of his most zealous followers. He considered the most infamous actions as natural necessities, and not at all criminal; teaching his disciples, that God required nothing of them but faith. Having been frequently driven out from place to place, he retired at last to Constantinople, where he died in the year 367. His followers after his death were called Eunomians, from Eunomus, a famous disciple of Aetius.

ETIOLOGY, that branch of physic which assigns the causes of diseases.

ETIOLOGY, in rhetoric, is deemed a figure of speech, whereby, in relating an event, we at the same time unfold the causes of it.

ETITE, or **ETITES**, in natural history, a name given to pebbles or stones of any kind, which have a loose nucleus rattling within them, and called in English the eagle-stone.

So far from being a particular genus of fossils themselves, we find *etite* among very different genera, as the geodes, heteropyrae, &c. but the most valued of all others, is that formed of the several varieties of our common pebbles. See **GEODES**, &c.

As to the foundation of *etite*, naturalists account for it from this consideration, that as the nuclei are coarser and more debased by earth than the rest of the pebble, they must shrink up and contract themselves into a smaller size; by which means, it will be separated from the surrounding crust, and thereby become loose.

Many imaginary virtues have been ascribed to these stones, as, that they assist women in labour, discover thieves, &c. than which nothing can be more ridiculous.

AFFECTATION, in language and conversation, is a vice too frequent in the fashionable world. It consists in expressing the most common and trifling thing in terms far fetched, and often ridiculously chosen. Nothing is so insupportable to a man of true wit, as one of these retailers of phrases; who would rather bring forth a few little pretinesses of expression, than be able to conceive the most strong, manly, and just ideas.

AFFECTATION, in writing, is nearly the same as in speaking: it is the vice of a weak, effeminate, fribbling mind. It discovers itself in poor, little, rickety thoughts, dressed up in language as variegated as a jack-pudding's coat, interspersed with the

prettiest-fancied latinisms, and phrases half French and half English.

AFFECTATION in behaviour is a strange and remarkable deportment of the body, occasioned by a desire to appear what a man is not, or to be taken notice of for something that he is. In the first case it is disagreeable, because it is an imposition or deceit, which is endeavoured to be put upon us; and it is equally so in the second; because it arises from vanity, or a too great attention to display some superiority. Affectation of all sorts is a violation of simplicity and of nature: in conversation and writing it arises from hunting eagerly after wit; in dress and behaviour, from searching after graces. There are some persons of so happy a mould, that they cannot acquire it; and others of so wretched a composition, that they cannot root it out of their texture.

AFFECTED Equations. See **AFFECTED**.

AFFECTION, in a general sense, implies an attribute that cannot be separated from its subject. Thus gravity is an affection of all bodies.

AFFECTION, in physics, the affections of a body are certain modifications produced by motion, in virtue of which, the body is disposed after such or such a manner. The affections of bodies are sometimes sub-divided into primary and secondary.

Primary affections are those which arise out of the idea of matter; as quantity and figure; or out of that of form, as that of quality and power; or out of both, as motion, place, and time.

Secondary, or derivative affections, are such as arise out of primary ones, as divisibility, continuity, contiguity, &c. which arise out of quantity; regularity, irregularity, &c. which arise out of figure.

AFFECTIONS of the Mind, are the same with passions, or inclinations. See the article **PASSION**.

AFFECTION, in medicine, a term used for any disorder with which a limb or other part of the body is affected. Thus, we say, hypochondriacal, or hysterical affection, &c. See the articles **HYPOCHONDRIACAL**, and **HYSTERIC**, &c.

AFFEERERS, or **AFFEERORS**, in law, persons appointed in court-leets, courts-baron, &c. to settle, upon oath, the fines to be imposed upon those who have been guilty of faults arbitrarily punishable; that is, such as have no express penalty assigned by statute.

AFFETTUOSO, or *con AFFETTO*, in the Italian music, intimates that the part to which it is added, ought to be played in a tender moving way, and consequently, rather slow than fast.

AFFIANCE, in law, denotes the mutual plighting of troth between a man and a woman, to marry each other.

AFFIDAVIT signifies an oath in writing, sworn before some person who is authorized to take the same.

In an affidavit, the time, place of habitation, and addition of the person who makes it, are to be inserted.

Affidavits are chiefly used to certify the serving of processes or other matters, concerning the proceedings in a court; and therefore should set forth the matter of fact to be proved, without taking any notice of the merits of the cause. They are read in court upon motions, but are not admitted in evidence at trials.

Westminster may commission persons in the several counties in England, to take affidavits relating to any thing depending in their several courts.

AFFINITY, *affinitas*, among civilians, denotes the relation of each of the parties married to the kindred of the other.

Affinity is distinguished into three kinds: 1. Direct affinity, or that subsisting between the husband and his wife's relations by blood; or between the wife and her husband's relations by blood. 2. Secondary affinity, or that which subsists between the husband and his wife's relations by marriage. 3. Collateral affinity, or that which subsists between the husband and the relations of his wife's relations. The degrees of affinity are always the same with those of consanguinity: hence, in whatever degree of consanguinity the kindred of one of the parties married are, they are in the same degree of affinity to the other.

AFFINITY is also used to denote a conformity, or agreement, between two or more things: thus, we say, the affinity of language, the affinity of words, the affinity of sounds, &c.

AFFIRMATION, among logicians, is the act of the mind asserting the truth or reality of something; or it is a positive proposition, declaring certain proportions or qualities to belong to the thing in question: thus, when I say, every circle is a perfectly round figure, I affirm perfect roundness to be an inseparable property of a circle.

AFFIRMATION is also used for the rectifying or confirming the sentence or decree of some inferior court: thus, we say, the House of Lords affirmed the decree of the lords of session.

AFFIRMATION also denotes a solemn attestation of the truth of some fact, which the Quakers are allowed to make instead of an oath.

AFFIRMATIVE, in a general sense, denotes any thing which implies an affirmation. See **AFFIRMATION**.

AFFIRMATIVE, in the Roman inquisition, a designation given to such heretics as openly avow the opinions they are charged withal.

AFFIRMATIVE Character. See the article **CHARACTER**.

AFFIRMATIVE Proposition. See the article **PROPOSITION**.

AFFIRMATIVE Quantity, in algebra, a real quantity, or a quantity greater than nothing; thus called in opposition to a privative or negative quantity, which is less than nothing.

AFFIRMATIVE Sign, in algebra, is marked thus +, and signifies that the quantity it is placed before has real existence, and is called an affirmative quantity. See **SIGN** and **CHARACTER**.

AFFORESTING, *afforestatio*, in our old law-books, is the turning lands into a forest, as the converting a forest to other uses, is called disafforesting, or deafforesting.

AFFRAY, or **AFFRAYMENT**, in law, formerly signified the crime of affrighting other persons, by appearing in unusual armour, brandishing a weapon, &c. But, at present, affray denotes a skirmish or fighting between two or more; and there must be a stroke given, otherwise it is no affray.

An affray is a common injury, punishable by the justices of peace in their sessions, by fine and imprisonment; and accordingly differs from assault, which is a private offence.

A constable may seize, and carry affrayers before a justice; as may likewise any private person.

AFFRONTÉE, in heraldry, an appellation given to animals facing one another on an escutcheon, a kind of bearing, which is otherwise called *confrontee*, and stands opposed to *adefsee*.

AFTER-BIRTH, in midwifery, the membranes which surrounded the infant in the womb, more usually called the secundines. See the articles **BIRTH**, **DELIVERY**, and **SECUNDINES**.

In brutes this is called the heam, or cleaning.

AFTER-MATH, in husbandry, signifies the grass which springs or grows up after mowing; or the grass, or stubble, cut after corn.

AFTER-PAINS, in midwifery, excessive pains felt in the groin, loins, &c. after the woman is delivered. See **DELIVERY**.

In order to guard against them, physicians recommend oil of sweet almonds, spermaceti, troches of myrrh and syrup of maiden-hair; and generally with success.

AFTER-SWARMS, in the management of bees, are those which leave the hive some time after the first has swarmed. See the articles **BEE** and **SWARM**.

AGA, in the Turkish language, signifies a great lord, or commander. Hence, the aga of the Janizaries is the commander in chief of that corps; as the general of the horse is denominated spahiclar aga. See the articles **JANIZARIES** and **SPAHI**.

AGANIPPIDES, in ancient poetry, a designation given to the muses, from a fountain of mount Helicon, called Aganippe.

AGA-

AGAPES, or **AGAPÆ**, a word made use of in ecclesiastical history, to signify those feasts of charity which were kept by the first Christians, when they were a proverb among the heathen, "Look how these Christians love one another!" The term is taken from the Greek word *αγαπη*, which signifies love. It was a repast which was made at night, in commemoration of our Saviour's last supper with his disciples: the rich furnished the expence, and the poor were invited. It concluded with a kiss of peace, and after it the holy sacrament was received.

Originally these love-feasts were pure and irreproachable, without disorder or licentiousness: but they gave occasion at last to the heathens to upbraid the Christians, and accuse them of the vilest and most flagitious practices. They continued for three centuries in the church, but were entirely prohibited by the councils of Laodicea and Carthage.

It is imagined by some commentators that St. Paul, in the 11th chapter of the 1st of the Corinthians, speaks of these feasts of charity, and not of the eucharist. Others are of opinion that they were not kept in commemoration of Christ's last supper, but were taken from the pagans. St. Austin reports that Faustus, the Manichean, reproached the faithful, because they had converted the sacrifices of the heathens into love-feasts. It seems as if the idea of these feasts of charity was taken from the Jews; who, when they sacrificed to the true God, kept a festival, and assembled together their kinsfolk and friends to partake of the sacrifice. Christianity was first planted in Judea; and it is rational to suppose that the first Christians might adopt so laudable a custom from the Jews. Being few in number, they considered themselves as one family: they were all brethren, and lived together in common: the spirit of charity instructed these repasts, where nothing was seen but order, temperance, and harmony. As they multiplied, they were still desirous to keep up their primitive customs; but abuse crept in, and the church was obliged to suppress them.

AGAPETÆ was a name given to those virgins who, thro' a motive of piety and charity, associated with the ecclesiastics, and attended upon them. They were originally their nearest relations; and in the pure days of primitive Christianity they lived together without reproach or scandal. In time however they degenerated into libertinism; and this promiscuous society was forbidden by the councils of the church. St. Athanasius mentions a priest named Leontius, who, to remove all occasions of slander, offered to castrate himself, that he might be permitted to retain his beloved companion.

AGARIC, *Agaricum*, in botany, a genus of epiphytal plants, growing on the trunks of trees, especially the larch-tree, and resembling the common mushroom, both in substance and structure.

Agaric is a fungus, of an irregular figure, three or four inches in length, and as many in breadth and thickness. It is extremely soft and elastic, taking an impression from the least touch, and resuming its former figure again: its colour, on the outside, is a pale yellowish white, but a pure white within.

It was much used by the ancients, as a sponge; but the present practice condemns it, as being not only disagreeable, but unsafe and pernicious.

Mineral AGARIC, in natural history, a light marly earth, so called on account of its resemblance to the vegetable agaric, in its colour and spongy texture.

It never constitutes a stratum of itself, but is found in cracks and fissures of rocks, roofs of caverns, and sometimes in the horizontal vacuities of these strata, in form of a white porous powder.

Mineral agaric is a good astringent, and therefore prescribed in fluxes, hæmorrhages, to dry old ulcers, stop defluxions of the eyes, &c.

AGAT, *Achates*, in natural history, a genus of semipellucid gems, variegated with veins and clouds, but have no zones like the onyx.

Agats are formed of a crystalline substance, variously debased with earths of different colours, to which is to be attributed the variety of their appearance. Thus, some have a white ground, as the *dendrachates*, or cocoa-stone, the *phassachates*, and another species. Others have a reddish ground, as the *hemachates*, *jardachates*, *corallo-achates*, &c. Others again a yellowish ground, as the *cerachates*, and *leonteseres*. And, lastly, some have a greenish ground, as the *jaspachates*, &c.

AGAT is also, the name of an instrument used by the gold wire-drawers; so called from the agat in the middle of it, which forms its principal part.

AGAVE, in botany. See **ALOE**.

AGE, in a general sense, denotes a certain portion, or part of duration, applied to the existence of particular objects: thus, we say, the age of the world, the age of Rome, &c. that is, the time, or number of years, elapsed since the creation of the world, or the building of Rome. Thus also, a man's age is the time he has lived, or the number of years elapsed since his birth; and so in other instances, as the age of a house, the age of a tree, &c.

The age of a horse, deer, &c. is known by several marks; for which see the articles **HORSE**, **DEER**, &c.

Chronologers are far from being agreed with respect to the age of the world; some making it more, some less. See the article **WORLD**.

AGE, is also used in a synonymous sense with century. See **CENTURY**.

AGE likewise denotes certain periods of the duration of the world.

Thus, among Christian chronologers, we meet with

with the age of the law of nature, which comprehends the whole time between Adam and Moses; the age of the Jewish law, which takes in all the time from Moses to Christ; and lastly, the age of grace, or the number of years since the birth of Christ.

Among ancient historians, the duration of the world is also subdivided into certain periods, called ages; of which they reckon three: the first, reaching from the creation to the deluge which happened in Greece during the reign of Ogyges, is called the obscure or uncertain age; the history of mankind, during that period, being altogether uncertain. The second, called the fabulous or heroic, terminates at the first olympiad; where the third, or historical age, commences.

The ancient poets also divided the duration of the world into four ages, or periods; the first of which they called the golden age; the second, the silver age; the third, the brazen age; and the fourth, the iron age. Not unlike these are the four ages of the world, as computed by the East-Indians, who extend them to a monstrous length.

AGE also denotes certain degrees or periods of human life, commonly reckoned four, viz. infancy, youth, manhood, and old age: the first of which extends to the fourteenth year; the second, to the twenty-fifth year; the third, to the fiftieth year; and the fourth, to the seventy-fifth year, or rather, as long as a man lives.

AGE, in law, signifies certain periods of life, when persons of both sexes are enabled to do certain acts, which for want of years and discretion they were incapable of before: thus, a man at twelve years of age ought to take the oath of allegiance to the king in a leet: at fourteen, which is his age of discretion, he may marry, choose his guardian, and claim his lands held in socage.

Twenty-one is called full age, a man or woman being then capable of acting for themselves, of managing their affairs, making contracts, disposing of their estates, and the like; which before that age they could not do.

A woman is dowable at nine years of age, may marry at twelve, and at fourteen choose her guardian.

If a man or woman acts in any of the above-mentioned capacities before the time prescribed by law, he or she may retract at that time, otherwise they are supposed to agree to it anew, and it shall be deemed valid. Thus, if a man marries before fourteen, or a woman before twelve, they may either agree to the marriage or not, at these several ages; and so on in other cases.

At fourteen, a man may dispose of his personal estate by will, but not of lands. At this age too a man or woman is first capable of being a witness, and under it persons are not generally punishable

for crimes, though they must satisfy the damage sustained by trespass committed by them.

AGE-PRIER, *Ætatem precari*, is when an action being brought against a person under age, for lands descended to him, he, by motion or petition, shews the matter to the court, praying the action may be stayed till his full age; which the court generally agrees to. However, as a purchaser, a minor shall not have his age-prier; nor in any writ of assize, of dower, or petition; but he may in any action of debt.

By the civil law the case is otherwise, an infant or minor being obliged to answer by his tutor or curator.

Among the Romans it was unlawful to put up for any public office, or magistracy, unless the candidate had attained to a certain age; which differed according to the offices sued for. Hence the phrases consular age, prætorian age, &c. See the articles CONSUL, PRÆTOR, &c.

AGE of the Moon, in astronomy, is the number of days that are past since her last conjunction with the sun, or from the day of her change. See the article MOON.

AGEMOGLANS, *Agiamoglans*, or *Aziamoglans*, in the Turkish customs, Christian children raised every third year, by way of tribute, from the Christians tolerated in the Turkish empire.

The collectors of this odious tax use to take one child out of three, pitching always upon the most handsome.

The word *agemoglan* properly signifies a barbarian's child; and out of their number, after being circumcised, and instructed in the religion and language of their tyrannical masters, are the janizaries recruited. As to those who are thought unfit for the army, they are employed in the lowest offices of the seraglio.

AGENDA, among philosophers and divines, signifies the duties which a man lies under an obligation to perform: thus we meet with the agenda of a Christian, or the duties he ought to perform, in opposition to the credenda, or things he is to believe.

AGENDA is more particularly used for divine service, in which sense we meet with *agenda matutina & vespertina*; that is, morning and evening prayers.

AGENT, in mechanics, a power which acts upon other bodies by virtue of its own motion, and by that action causes or effects a change therein. See ACTION or MOTION.

Agents are either natural or moral. *Natural AGENTS* are all such inanimate bodies, as have a power to act upon other bodies in a certain and determinate manner: such is fire, which has the invariable property or power to warm or heat.

Moral AGENTS, on the contrary, are rational creatures,

creatures, capable of regulating their actions by a certain rule.

These are otherwise called free or voluntary agents.

AGENTS, among physicians and chemists, an appellation given to all kinds of menstruums.

AGENT is also used to denote a person entrusted with the management of an affair, whether belonging to a society, company, or private person; thus we say, agents of the Exchequer, of the Victualling-office, &c.

AGENT and Patient, in law, is said of a person who is the doer of any thing, and also the party to whom it is done. Thus, if a man who is indebted to another, makes his creditor his executor, and dies, the executor may retain so much of the goods of the deceased as will satisfy his debt; by which means he becomes agent and patient; that is, the person to whom the debt is due, and the person who pays it.

AGER, in Roman antiquity, a certain portion of land allowed to each citizen. See the article AGRARIAN LAW.

AGER is also used, in middle-age writers, for an acre of land. See the article ACRE.

AGERATUM, in botany, the bastard hemp agrimony, a plant which produces male and female and hermaphrodite floscules in one common empanement; it contains five short hairy filaments, with an oblong germen, in which are situated several angulated oblong downy seeds.—This plant was antiently known among the Greeks by the name of eupatorium; the leaves are recommended as vulnerary and hepatic; also to dissolve hard tumours, and absorb superfluous humidities. The maudlin, which is also called ageratum, is not of this genus, but a species of the achillea. See ACHILLEA and MAUDLIN.

AGGER, in the ancient military art, a bank or rampart, composed of various materials, as earth, boughs of trees, &c.

The agger of the ancients was of the same nature with what the moderns call lines.

AGGER was also used in several other senses, as for a wall or bulwark to keep off the sea; for the middle part of a military road, usually raised into a ridge; and sometimes for the heap of earth raised over graves, more commonly called tumuli.

AGGLUTINANTS, *Agglutinantia*, in pharmacy, &c. make a class of strengthening medicines, of a glutinous or viscid nature; which, by repairing adhering to the solids, contribute greatly to repair their loss.

AGGLUTINATION, in a general sense, denotes the joining two or more things together, by means of a proper glue or cement.

AGGLUTINATION, among physicians, signifies either the adherence of new substance, or the giv-

ing a glutinous consistence to the animal fluids, whereby they become more fit for nourishing the body.

AGGREGATE is much the same as the sum arising from the addition or collection of several things together, the whole of which is called the aggregate, sum, or total.

AGGREGATION, in natural philosophy, is a particular kind of union or association of several things which have no natural connection one with the other by nature; but by some artificial means are collected together so as to form one whole. Thus a house is a body of aggregation, being formed of wood, stone, mortar, &c. which have no natural connection one with the other.

AGGRESSOR, among lawyers, denotes the person who began a quarrel, or made the first assault.

It is a very material point to know who was the first aggressor, and accordingly never fails to be strictly enquired into.

AGIADES, in the Turkish armies, denote a kind of pioneers employed in fortifying camps, and the like offices.

AGIO, in commerce, a term chiefly used in Holland and at Venice, where it denotes the difference between the value of bank-stock and the current coin.

AGIO is also used for the profit arising from the discounting a note, bill, &c.

AGISTMENT, AGISTAGE, or AGISTATION, in law, the taking in other people's cattle to graze, at so much per month.

The term is peculiarly used for the taking in cattle to be fed in the king's forests, as well as for the profits thence arising.

AGISTMENT is also used in a metaphorical sense, for any tax, burden, or charge: thus, the tax levied for repairing the banks of Romney-marsh was called *agistmentum*.

AGISTOR, or AGISTATOR, an officer belonging to forests, who has the care of the cattle taken in to be grazed, and levies the monies due on that account.

There are four such agistors in each forest, all created by letters patent, and commonly called guest-takers, or gift-takers.

AGITATION, in physics, a brisk intestine motion of the small corpuscles of any natural body. Thus fermentation and effervescence are produced by a quick agitation of the particles of the fermenting body: fire likewise agitates the most subtle particles of matter. See FIRE.

AGLAOPHOTIS, in botany, a term used sometimes for piony. See the article PIONY.

AGLECTS, AGLETS, or AGREEDS, among botanists, the same with what is usually called apices. See APICES.

AGLIA, a term used by ancient physicians for a whitish spot in the eye, caused by a congestion of humours.

AGNATION, *Agnatio*, among civilians, denotes the relation of kinship subsisting between the descendants of the same man, in the male line.

AGNOETÆ, in church history, a sect of heretics, so called on account of their maintaining that Christ, with respect to his human nature, was ignorant of many things, and particularly of the day of judgment; an opinion which they built upon the text, Mark xiii. 32. whereof the most natural meaning is, that the knowledge of the day of judgment does not concern our Saviour, considered in the character of Messiah.

AGNOETISM, among ecclesiastical writers, signifies the doctrine or heresy of the agnoetæ. See **AGNOETÆ**.

AGNOMEN, in Roman antiquity, a kind of fourth or honorary name, given to a person on account of some extraordinary action, virtue, or other accomplishment. Thus the agnomen Africanus was bestowed upon Publius Cornelius Scipio, on account of his great achievements in Africa.

AGNUS, the lamb, in zoology, the young of the sheep kind; for the proper treatment of which, see the article **LAMB**.

AGNUS Castus, in botany, the chaste tree, so called on supposition that it allayed lust, by cooling the genital parts when heated by seminal turgescentcy. In the present medical practice it is but little used. Botanists enumerate five species of these plants, which are all classed under the general name vitex. See **VITEX**.

AGNUS Dei, in the church of Rome, a cake of wax stamped with the figure of a lamb supporting a cross.

These being consecrated by the pope with great solemnity, and distributed among the people, are supposed to have great virtues; as to preserve those who carry them worthily, and with faith, from all manner of accidents, to expel evil spirits, &c.

AGNUS Dei, is also a popular name for that part of the mass, where the priest strikes his breast thrice, and says the prayer beginning with the words *agnus dei*.

AGNUS Scythicus, in natural history, the name of a fictitious plant, resembling a lamb, said to grow in Tartary.

Kæmpfer, who was in the country, could not by the most diligent enquiry, find any account of it; and therefore concludes the whole to be a fiction.

AGONALIA, in Roman antiquity, festivals celebrated in honour of Janus, or of the god Agonius, whom the Romans invoked before undertaking any affair of importance.

They seem to have been kept three times in the year, viz. on the fifth of the ides of January, on

the twelfth of the calends of June, and on the third of the ides of December.

AGONOTHETA, or **AGONOTHETES**, in Grecian antiquity, was the president or superintendent of the sacred games; who not only defrayed the expences attending them, but inspected the manners and discipline of the athletæ, and adjudged the prizes to the victors.

AGONY, among physicians, denotes extreme pain, or the utmost efforts of nature struggling with a disease.

AGONY, in a more limited sense, is used for the pangs of death; which are less painful than usually imagined, the body being then incapable of quick sensations. See **DEATH**.

AGONYCLITE, or **AGONYCLITES**, in church history, a sect of Christians, in the seventh century, who prayed always standing, as thinking it unlawful to kneel.

AGRARIAN Stations, *agrariæ stationes*, in the Roman art of war, were a kind of advanced guards posted in the fields.

AGRARIAN Lotus, among the same people, those relating to the division and distribution of lands; of which there were a great number: but that called the Agrarian Law, by way of eminence, was published by Spurius Cassius, about the year of Rome 268, for dividing the conquered lands equally among all the citizens, and limiting the number of acres which each citizen might enjoy.

Harrington, in his *Oceana*, thinks an agrarian law the only basis of liberty; through the want of which, or the non-observance of it, the commonwealth of Rome came to ruin. He likewise lays down the plan of an agrarian law for England, whereby no man should be allowed to possess more than 2000 l. a year in lands.

AGREEMENT, in law, signifies the consent of several persons to any thing done.

There are three kinds of agreement. First, an agreement already executed at the beginning, as when money is paid, or other satisfaction made for the thing agreed to. Secondly, an agreement after an act done by another, to which a person agrees: this is also executed. Thirdly, an agreement executory, or to be executed in time to come.

An agreement put in writing does not change its nature, but if it be sealed and delivered, it becomes still stronger; nay, any writing under hand and seal, or a proviso amounting to an agreement, is equivalent to a covenant.

AGRICULTURE, in a general sense, denotes the art of rendering the earth fertile by tillage and culture. In this sense, it comprehends gardening, as well as husbandry. See the articles **GARDENING** and **HUSBANDRY**.

AGRICULTURE is more particularly used for the management

management of arable lands, by ploughing, fallowing, manuring, &c. See the article **PLOUGHING**, &c.

Agriculture is a no less honourable than profitable art, holding the highest esteem among the ancients, and equally valued by the moderns.

The Egyptians ascribed the invention of agriculture to Osiris; the Greeks to Ceres and her son Triptolemus; and the Italians to Saturn, or Janus: but the Jews, with more reason, ascribe this honour to Noah, who, immediately after the flood, set about tilling the ground and planting vineyards.

Agriculture has been the delight of the greatest men. We are told, that Cyrus the Younger planted and cultivated his garden, in a great measure, with his own hands; and it is well known, that the Romans took many of their best generals from the plough.

But not to detain the reader with a needless encomium of this universally admired art, we shall here subjoin its principal branches, which will be treated of under their respective articles.

Agriculture, then, may be subdivided into the proper management of all kinds of arable lands, whether of a clayey, sandy, loamy, or whatever other soil. See the articles **CLAY-LANDS**, **SANDY-LANDS**, &c.

2. Of lands employed in pasturage, whether they be meadow-lands, marshy-lands, &c. See **MEADOW-LANDS**, &c.

3. Of wood-lands, or those laid out in nurseries, plantations, forests, woods, &c. See the article **WOOD-LANDS**, &c.

AGRIFOLIUM, or **AQUIFOLIUM**, in botany. See **ILEX**.

AGRIMONOIDES, in botany, a plant bearing rosaceous flowers; it is classed by Linnæus with the agrimonia.

AGRIMONIA, in botany, agrimony, a genus of plants of different species; the sort which is best known in the shops, grows wild in several parts of England: the flower, which is rosaceous and pentapetalous, contains a monophylous cup, accurately divided into five segments; in the center, two styles rest on the germen, surrounded by twelve capillary filaments, whose bases are inserted in the calyx. When the flower is decayed, the germen becomes two roundish seeds, fastened to the emplace.

The leaves of this plant make a very pleasant tea, and are said to be good in the jaundice, in cachectic cases, and in obstructions of the liver and spleen.

AGRIPPA, a denomination given by ancient as well as modern physicians, to children born with the feet foremost. See the article **DELIVERY**.

AGROM, in medicine, a disorder incident to the people of the East-Indies, wherein their tongues cleave in several places.

The remedy for this disease, which they attribute to an extreme heat in the stomach, is to chew the black seeded basilica, and to drink a chalybeated liquor, or the juice of large mint.

AGROSTEMA, in botany, a genus of decandrious plants, according to Linnæus; but better known by the name of *lychnis*, or *campion*. See **LYCHNIS**.

AGROSTIS, in botany, a genus of triandrious plants, whose flowers are composed of two pointed valves, one shorter than the other, terminated with a beard; the germen is round, supporting two reflexed styles, with three capillary filaments, and produces single seeds edged on both sides. These plants are very troublesome weeds in gardens, and is commonly called in English, couch or quick grass.

AGROSTAGRAPHIA, among naturalists, signifies the history or description of grasses. Such is that of Scheuchzer, containing an accurate description of several hundreds species of grass.

AGRYPNIA, in a general sense, denotes much the same with watchfulness, or an inaptitude to sleep; which is a very troublesome symptom of feverish and other disorders. See the article **WATCHING**.

AQUAPECACO, in ornithology, a Brazilian bird of the moor-hen kind, about the size of a pigeon, very long-legged, with a beak like that of a common hen; its back and the upper part of its wings are brown; and in each wing there is a small horn, or prickle, serving the bird as a defensive weapon.

AGUE, a general name for all periodical fevers, which, according to the different times of the return of the feverish paroxysm, or fit, are denominated quotidian, tertian, or quartan agues. See the article **QUOTIDIAN**, &c.

Agues are thought to be owing to a suppression of perspiration, as their more immediate cause, whether that be occasioned by a foggy and moist air, or by putrid damps; but their *causa proxima* seems to be an actual corruption of the humours of the body.

Dr. Pringle thinks the best way of accounting for the periodic returns, is upon the principle of putrefaction. The heat of the body, he observes, varies little, and therefore the corruption produced in any of the humours must happen in a determinate time. If we suppose, that in the paroxysm, the more corrupted particles of the blood do not all pass off through the skin with the sweat, but that some part of them are discharged with the bile; these particles coming into the intestines, and being from thence taken up by the lacteals, and carried into the blood, may there act as a new ferment and occasion a return of the fit. Thus, the corruption of the bile may be the effect of the first fit, and the cause of them that ensue.

The doctor farther observes, that though all moist countries are subject to agues of some kind or other; yet if the moisture is pure, and the summers are not close and hot, they will mostly appear in a regular tertian shape, and be easily cured. But if the moisture arises from long stagnating water, in which plants, fishes, and insects, die and rot, then the damps, being of a putrid nature, not only occasion more frequent, but more dangerous fevers, which oftener appear in the form of quotidian, and double tertian, than that of single ones.

It is remarkable how much these fevers vary with the season; for however frequent, violent, or dangerous they are in the decline of summer, or beginning of autumn, when the putrefaction is highest; yet before winter they are commonly reduced to a small number, become mild, and generally assume a regular tertian form.

AGUE-Tree, a name by which some call *salisfras*, on account of its febrifuge qualities.

AGUTI, in zoology, an American quadruped of the rat-kind, of the size of the Guinea-pig, which it greatly resembles: its hairs are rigid and glossy, of a mixed colour between red and brown, with more or less of black; its whiskers are like those of the rabbit-kind; but like the hog, its upper-chop is longer than the under one; its upper-lip is split, like that of the hare; its tail is very short, the eyes are prominent, and the legs are altogether, or almost naked.

AHICCYATLI, in zoology, an American serpent, nearly allied to the hæmorrhous and rattlesnake; only that it is larger than the former, and wants the rattle of the latter. Its poison is as fatal as any yet known.

AID, in a general sense, denotes any kind of assistance given by one person to another.

AID, or *Ayde*, in law, denotes a petition made in court to call in help from another person, who has interest in land, or other thing contested. This is called *aid prier*, which not only strengthens the party that prays for the aid, but gives the other person an opportunity of avoiding a prejudice that might otherwise accrue to his own right. Thus, a tenant for life may pray aid of the person in reversion; and a city, or borough, that holds a fee-farm of the king, if any thing be demanded of them, may pray for aid of the king.

AID-DE-CAMP, in military affairs, an officer employed to receive and carry the orders of a general. They ought to be alert in comprehending, and punctual and distinct in delivering them.

In the French armies every general is allowed four aids-de camp, a lieutenant-general two, and a marshal-de-camp one.

AID-MAJOR, the French term for an adjutant. See the article **ADJUTANT**.

AID, *auxilium*, in ancient customs, a subsidy paid by vassals to their lord, on certain occasions.

Such were the aid of relief, paid upon the death of the lord mesne, to his heir; the *aid cheval*, or capital aid, due to the chief lord on several occasions; as to make his eldest son a knight, to make up a portion for marrying his daughter; and so in other cases.

Royal Aid, an appellation sometimes given to the land-tax.

AIDS, in the menage, are the same with what some writers call cherishings, and used to avoid the necessity of corrections.

The inner heel, inner leg, inner rein, &c. are called inner aids; as the outer heel, the outer leg, outer rein, &c. are called outer aids.

AIGUISCE, *Aiguisse*, or *EGUISCE*, in heraldry, denotes a cross with its four ends sharpened, but so as to terminate in obtuse angles.

It differs from the cross fitchée, inasmuch as the latter goes tapering by degrees to a point, and the former only at the ends.

AILE, or **AIEL**, in law, a writ which lies where a person's grand-father, or great-grand-father being seised of lands, &c. in fee-simple the day that he died, and a stranger abates or enters the same day, and dispossesses the heir of his inheritance.

AIR, in physiology, from the Greek *ang*, signifying the same thing. A light, fluid, transparent body, capable of compression and dilatation, which covers this terrestrial globe, and surrounds it to a considerable height.

The ancients considered air as an element, tho' it be most certain that air taken in the ordinary acceptance, is very far from the simplicity of an elementary substance, notwithstanding some of its parts may merit that denomination. Wherefore air may be distinguished into vulgar or heterogeneous, and proper or elementary.

Vulgar or heterogeneous air, is an assemblage of corpuscles of various kinds, constituting all together a fluid mass, wherein we live and move, and inspire and expire it alternately: which total mass, we call atmosphere. See **ATMOSPHERE**.

The heterogeneous substances of which the air consists, may be reduced to two sorts: namely, first, the matter of light or fire, perpetually flowing from the heavenly bodies. See **FIRE**. To which some naturalists add electric and magnetic exhalations from the earth. See **ELECTRICITY**, and **MAGNETISM**. Secondly, The infinite number of particles raised under the form of vapours or exhalations from the sea, rivers, minerals, vegetables, or animals; whether by the heat of the sun, subterraneous fires, or chimneys, and other artificial fires. See **EXHALATION**, and **VAPOUR**.

Sir Isaac Newton conceives the confused mass of vapours, air, and exhalations, which we call the atmosphere, to be nothing else but the particles of all sorts of bodies, of which the earth consists, separated and kept at a distance by rarefied æther. See *ÆTHER*.

Elementary air, or air properly so called, is a subtle, homogeneous and elastic substance, being the basis, or as we may say, the fundamental ingredient of the whole air of the atmosphere, from whence it takes its name.

Sir Isaac Newton observes again, that if it be considered how by the continual fermentations raised in the bowels of the earth, there are real substances raised out of all kinds of bodies; it may not perhaps be thought absurd, that the most permanent part of the atmosphere, which is the true air, should be constituted of these; especially since they are the heaviest of all others, and so must subside to the lower part of the atmosphere, and float upon the surface of the earth, and buoy up the lighter exhalations and vapours to float in great plenty above them: for the air, as in reason it ought to be esteemed the most ponderous part of the atmosphere, because the lowest, so it betrays its ponderosity by making vapours ascend readily in it, by sustaining mists, and clouds of snow, and by buoying up gross and ponderous smoke. The proper air is also the most gross and inactive part of the atmosphere, affording living things no nourishment, if deprived of the more tender exhalations and spirits that float in it: and what more inactive and remote from nourishment than metallic bodies?

Proper air has a multitude of characteristics, the most considerable of which are the following:

If air be close confined in a metalline or glass vessel, it will remain the same, without any alteration, ever preserving the form of air: but this does not hold good of vapours; which, as soon as they grow old, lose their whole elasticity, adhere to the inner surface of the glass, and at length trickle down to the bottom. It is almost the same with the exhalations of other bodies, they becoming in a manner inflexible and lost after their elasticity is gone. This is confirmed by many of Mr. Boyle's experiments on the air drawn from grapes, dough, flesh, and other substances: and further still by Dr. Hales's experiments in his *Vegetable Statics*, &c.

By the means of air terrestrial bodies once on fire, continue to burn, till all their parts which contain any fire are consumed; on the contrary, vapours and exhalations extinguish the quickest fire in an instant, and even red hot iron. Vapours also, instead of being necessary to respiration, as air is, are frequently detrimental thereto, and sometimes occasion suffocation; instances of which we have in

burning brimstone, and the grotto *Del Cami*, in Italy, which brings on sudden death.

If air be not a fluid distinct from vapours and exhalations, how comes it that it continues ever the same, after heavy rains accompanied with thunder and lightning? The truth is, when it lightens exhalations are set on fire, and fall on the earth in the form of rain and vapour: but after the rain there is no sensible change in the air, except that it is remarkably purified; it must therefore be of a different nature from terrestrial exhalations.

To speak the truth, our knowledge of the substance and intimate nature of the air amounts to a very small matter; what authors have hitherto said about it being but mere conjecture. There is no way of examining air pure and defecated from the several things which are intermixed with it: consequently there is no saying what is its particular nature.

Dr. Hook will have it to be no other than æther, or that fluid and active matter which is distributed through all the celestial regions. See *ÆTHER* and *MEDIUM*.

Considered as such, it is a substance *sui generis*, and independent of any other, incorruptible, immutable, present in all places and in all bodies.

Other philosophers place its essence in its elasticity, and make that its distinguishing characteristic. These suppose that it may be generated, and that it is nothing else but the matter of other bodies, rendered by the changes it has undergone, susceptible of a permanent elasticity. Mr. Boyle produces a number of experiments, which he made himself upon the production of air. What this gentleman calls production of air, is the extraction of a sensible quantity of air from a body wherein there appeared to be none at all, or at least far less than the quantity extracted. He observes that among the different methods proper for this effect, the best are fermentation, corrosion, dissolution, decomposition, ebullition of water and other fluids, the reciprocal action of bodies, especially saline ones, upon one another; he adds, that different solid and mineral bodies, in the parts of which there could not be conceived to be any elasticity, being plunged into corrosive mediums, which also are utterly unelastic, will produce, by means of the attenuation of their parts from their mutual collision, a considerable quantity of elastic air.

Sir Isaac Newton is of the same opinion, according to whom the particles of a dense compact fixed substance, adhering to each other by a powerful attractive force, cannot be separated but by a violent heat, and perhaps never without fermentation; and these bodies rarefied by heat and fermentation are finally transformed into a truly elastic air. On these principles, he adds, gunpowder produces air upon explosion.

Here

Here then are not only the materials for producing air, but likewise the mode of doing it; in consequence of which air may be distinguished into real or permanent, and apparent or transitory. For to be satisfied that every thing which has the appearance of air, is not really such, the instance of the æolipile is sufficient, where water being sufficiently rarefied by fire, issues out with a sharp hissing, under a form perfectly resembling that of air; but soon after loses that resemblance, especially in the cold, and becomes water again by condensation, just such as it was originally. The same thing may be observed in spirit of wine, and other subtile and fugitive spirits obtainable by distillation; whereas real air cannot by compression, condensation, or any other means, be converted into any other substance but air. See *ÆOLIPILE*.

And as water may be made to assume the appearance of air for some time, but soon after resumes its own; so it is the same with other fluids; the greatest subtilization they can be made to undergo, is reducing them to vapours, which consist in a fluid extremely rarefied, and agitated by a very brisk motion. For in order to render a substance proper to become a permanent air, it must be of a fixed nature; otherwise it cannot undergo the necessary transmutation, but will soon fly off and be dissipated. So that the difference between transitory and permanent air, answers to that between vapours and exhalations, which consists in this, that the one are dry and the other moist. See *VAPOUR* and *EXHALATION*.

Many make the elasticity of air to consist in the figure of its particles. Some will have them to be small locks, like those of wool or raw silk; others conceive them to be circumvolved like spiral springs, endeavouring to unbind themselves in virtue of their contexture; so that to produce air, is, according to these naturalists, to produce particles in such a manner disposed, there being none but such that are susceptible of the like disposition. Whence, they add, fluids are altogether incapable of it, on account of the roundness, smoothness, and lubricity of their parts.

But Sir Isaac Newton advances a different system. He does not think such a contexture of parts sufficient to account for that surprizing elasticity we find in air, which may be so rarefied as to occupy a space a million of times greater than that which it possessed before its rarefaction. But as he insists that all bodies have an attractive and repulsive power, and that these two qualities are by so much stronger as the bodies are more dense, solid, and compact; he thence concludes, that when by heat, or the effect of some other agent, the attractive force is overcome, and the particles of the body are set so far asunder, as to be no longer within the sphere of attraction, the repulsive force beginning to act, causes them to separate further

asunder, with a force proportional to that by which they before adhered together; and after this manner is permanent air formed. This is the reason, says the same author, why permanent air, consisting of proper particles, and formed of denser bodies than transitory air or vapours, is heavier, and a humid atmosphere lighter than a dry one. See *ATTRACTION* and *REPULSION*.

After all, there is to doubt, if the substance thus extracted from solid bodies be true air; in a word, whether it be not transitory air, or if permanent air, whether it did not before exist in the bodies from whence it is extracted. Mr. Boyle proves from an experiment made in his pneumatic machine with a lighted match, that the subtile fume which fire raises, even from dry bodies, has not so much of springiness as air, since it cannot hinder the expansion of a small quantity of air inclosed in a bladder which it surrounds. Nevertheless, in some experiment which he made afterwards, by dissolving iron in oil of vitriol and water, or in aqua fortis, he found a large bubble of air which was truly elastic, and which in consequence of its spring, hindered the neighbouring liquor from possessing its place. A very warm hand applied to it caused it easily to dilate like other air, and to separate in the liquor into a multitude of bubbles, some of which emerged up through the liquor into the open air.

The same gentleman assures us, that he has separated a truly elastic substance from several other bodies; as bread, grapes, beer, apples, pease, beef, &c. and from certain bodies, by burning them in vacuo, particularly from paper and hartsorn: however, that this substance, upon a close examination, proved of so different a nature from pure air, that animals included in it, not only could not respire but with great pain, but died sooner than if they had been shut up in vacuo, without any air at all.

To this may be added, an observation of the Parisian Royal Academy of Sciences; namely, that elasticity is so far from being a constitutive quality of the air, that, on the contrary, if certain heterogeneous substances be mixed with the air, it becomes thereby more elastic than it is in its utmost purity. And M. de Fontenelle asserts, in consequence of some experiments made at Paris by M. de la Hire, and at Bologna by Sig. Stancari, that air moistened by vapours, is far more elastic and capable of expansion, than when it is pure; nay, in the opinion of M. de la Hire, even eight times more elastic than dry air.

But it should be observed at the same time, that Dr. Jurin explains these experiments in another manner, and insists that the consequence the French philosophers have drawn from, is by no means a necessary one.

All that has been hitherto said, is to be understood of air considered in itself; but, as we have remarked, no air is to be found pure of all mixture.

ture. However, those heterogeneous substances, whose properties and effects we are to consider, are, according to the great Boyle, of a very different nature from pure air. Boerhaave comes after, and takes upon him to prove that it is a chaos, a meer jumble of all species of created bodies. Whatever fire is capable of elevating, rises into the air; and what body is there able to resist the action of fire? See FIRE, VOLATILE, &c.

Particles of every substance belonging to the mineral kingdom, must be intermixed with air; for all of them, salts, sulphurs, stones, metals, &c. are convertible into smoke, and consequently must take place among aerial substances. Gold itself, the most fixed of all natural bodies, is found among ores, closely combined with sulphur, and consequently may be elevated together with that mineral. See GOLD, &c.

It is altogether as certain, that in air there must be particles of every substance belonging to the animal kingdom. For the abundant emanations which are perpetually issuing from the bodies of animals, in the transpiration continually kept up by the vital heat, are absorbed into the air; and in such quantities too, during the course of an animal life, that, could they be recollected, they would be sufficient to compose a good round number of the like animals. See TRANSPIRATION, EMANATION, &c.

Furthermore, when a dead animal continues exposed to the air, all its particles evaporate, and are quickly dissipated; so that the substance which composed such animal, whether man, ox, or any other, is almost wholly converted into air.

One proof, among a thousand others, that the air is charged with an infinity of excrementitious particles, is this. At Madrid, we are told, that there are few or no necessary houses, and that their streets are the nightly receptacles of all ordures: Yet that the air so speedily carries off those fetid particles, that none of their scent remains the next day.

No less true is it, that the air is charged with vegetable particles; for 'tis sufficiently known, how readily those substances putrefy, and thereby become volatile, without excepting even the more solid and vascular parts of them.

Of all the emanations which float in the vast ocean of the atmosphere, the principal are such as consist of saline particles. Many writers suppose them to be of a nitrous kind; tho' there is little reason to doubt that there are some of all sorts; vitriol, alum, marine salt, and an infinity of others.

Mr. Boyle thinks, that there may be a large quantity of compound salts, not to be met with on or in the bowels of the earth, formed of the fortuitous concourse and mixture of different saline spirits. We frequently find the window-glass of

ancient buildings corroded, as if eaten by worms; and we know of no particular salt that is capable of producing such an effect.

Sulphur is no inconsiderable part of the aerial substance, on account of the great number of volcanos, grotts, caverns, and spiracles, which are constantly belching up fumes of this species.

Lastly, the separations, frictions, dissolutions, and, in general, the mutual operations of various substances upon one another, may be regarded as the sources of an inconceivable quantity of anonymous particles, which rise and float in the air.

Air, taken in the general acceptation, is one of the most considerable and universal agents in nature, both for maintaining animal life, and producing the most important phenomena which happen upon the earth. Its properties and effects, having been the most principal objects of the researches and discoveries of modern philosophers, they have been reduced to certain laws and demonstrations, which make no inconsiderable branches of mixed mathematics, under the titles of Pneumatics, Aerometry, &c. which see.

Among the properties and mechanical effects of the air, the principal ones are its fluidity, its weight, and its elasticity.

The great fluidity of the air is manifest from the facility with which bodies traverse it, by the propagation of sounds, odours, and emanations of every kind that escape from bodies; these effects imply a body whose parts yield to the slightest effort; and in yielding, move themselves with the greatest freedom; and now this is the very thing which constitutes fluidity. Air never loses this property, whether it be kept years together confined in glass vessels, or is exposed to the greatest natural or artificial cold, or condensed by the most powerful pressure. In none of these circumstances, has it ever been found reduced to a solidity of parts; this is owing to its rarity, mobility, and the figure of its parts. See FLUID.

The Cartesians make fluidity to consist in a perpetual intestine motion of the parts, and think they can prove that this character belongs to air. Thus, in a camera obscura, where the representations of external objects are introduced by a single ray, the corpuscles with which the air is replete, are seen to be in a continual fluctuation. Some moderns attribute the fluidity of the air to the fire which is intermixed with it; without which, say they, the whole atmosphere would harden into a solid impenetrable mass; and indeed it must be allowed, that the greater the quantity of fire is that it contains, the greater will its fluidity, mobility, and permeability be; and according as the different positions of the sun augment or diminish the degree of fire, the air always receives a proportional temperature, which doubtless is the reason why on the tops of high mountains, the senses of hear-

ing,

ing, smelling, &c. are evidently weakened. See FIRE.

The air, as a fluid, presses with the same force in all directions. M. Mariotte proves the lateral pressure of air to be equal to its perpendicular pressure, by the following experiment. He takes a tall glass vessel, perforated near the middle with a small hole, which when stopped up, and the vessel filled with water, he plunges into it a glass tube open at both ends, 'till its bottom extremity is lower than the little hole in the side of the vessel. Then he closes the mouth of the vessel with wax of pitch, with which he likewise encompasses the tube; so that no air can gain admittance between the tube and the neck of the vessel: Now when the tube is filled with water, and the hole in the side of the bottle is opened, the water runs out in part from the tube; but near the lower end of the tube, at the height of the hole, it stops, and the whole vessel remains full. If then the perpendicular pressure of the air were greater than its lateral pressure, all the water would be forced out of the tube; but this does not happen, because the air presses laterally with the same force against the hole, so that no water can escape out of the vessel.

The weight or gravity of the air, is a property of it arising out of its corporeal substance; for gravity is a property, essential to matter, or at least a property that is found in all bodies. See ATTRACTION, GRAVITY, and WEIGHT.

Notwithstanding we have infinite proofs of the gravitating property of the air continually at hand; yet the discovery of it is certainly owing to the moderns. Many of the phenomena which it occasions, have, it is true, been taken notice of time out of mind. It was known many centuries ago, that upon sucking the air contained in an open pipe, whose lower extremity is immersed in water, this fluid rises above its level, and takes place of the air. In consequence of such observation sucking pumps were contrived, and divers other hydraulic inventions, as Heron's syphons described in his Pneumatics, and the watering-pots known in Aristotle's time under the name of *Clepsydræ*, which run or stop, as the finger leaves open or closes their upper orifice. The reason that philosophers assigned for this, was a pretended horror that nature conceives for a vacuum, and rather than endure it, chooses to make a body ascend contrary to the solicitation of its own gravity. Even Galilæo, with all his sagacity, could not hit upon any thing more satisfactory; for he only assigned limits to this dread of vacuity. Having observed that sucking pumps would not raise water higher than 16 brasses, or 34 English feet, he limited this force of nature to avoid a vacuum, to one that was equivalent to the weight of a column of water 34 feet high, on the base of the void space. Consequently he pointed out a way of making a vacuum, by means of a

hollow cylinder, whose piston is charged with a weight sufficient to detach it from the close bottom turned upwards. This effort he called the measure of the force of vacuity, and made use of it for explaining the cohesion of the parts of bodies. See CLEPSYDRA, PUMP, VACUUM, &c.

Galilæo however was not altogether ignorant of the weight of the air. He shews two ways of demonstrating it in his Dialogues. The path was easy from one discovery to another, yet still Galilæo's knowledge of the matter was imperfect.

At length Torricelli fell upon the lucky guess that the counterpoise which keeps fluids above their level, when nothing presses upon their internal surface, is the mass of air resting upon the external surface. He came at it in the following manner: in 1643, this disciple of Galilæo being set upon executing a little experiment on the vacuum formed in pumps, above the column of water, when it exceeds 34 feet, thought of using a fluid heavier than water, such as quicksilver. He supposed that, whatsoever was the cause that sustained a column of 34 feet above its level, the same force would sustain a column of any other fluid, which weighed as much as the column of water on the same base; whence he concluded that quicksilver, being about 14 times as heavy as water, would not be kept up higher than 29 or 30 inches. He therefore took a glass tube of several feet in length, sealed it hermetically at one end, and filled it with quicksilver; then inverting it upright, by pressing his finger against the open orifice, he plunged it into a vessel of quicksilver, and suffering the fluid to run out, the event verified his conjecture; the quicksilver, faithful to the laws of hydrostatics, descended till the column of it above the surface of that in the reservoir, was about 30 inches high.

Toricelli's experiment became famous in a short time. Father Merfenne, who kept up a literary correspondence with most of the literati in Italy, was informed of it in 1664, and communicated it to those of France, who presently repeated it: the famous Messrs. Pascal and Petit, curious naturalists at that time, were the first who made it, and varied it different ways. This occasioned the ingenious treatise which M. Pascal published at 23 years of age, under the title of, *Expériences Nouvelles touchant la Vuide*, which rendered his name famous throughout Europe.

Toricelli reflecting on the cause of this phenomenon, was at length led to conclude; that the weight of the air incumbent on the surface of the stagnated quicksilver, was the thing that counterbalanced the fluid contained in the tube. See TORRICELLIAN EXPERIMENT.

In reality M. Pascal, who, in the abovementioned treatise, made use of the principle of *fuga vacui*, having, as he says, some glimmering notion

of the weight of the air, quickly adopted Torricelli's idea, and devised several experiments to confirm it, one of which was to procure a vacuum above the reservoir of quicksilver. In this case he found the column sink down to the level; but this appearing to him not sufficiently powerful to dissipate the prejudices of the ancient philosophy, he prevailed on a brother-in-law, M. Perier, to execute the famous experiment of Puy-de-Dome, so universally known, as not to need a recital here. M. Perier observes that the height of the quicksilver half way up the mountain was less by some inches than at the foot of it, and still less at the top; so that it was now plain that it was the weight of the atmosphere which counterpoised the quicksilver.

We should not omit some instances of the sagacity of Des Cartes with regard to the phenomenon we have been speaking of. There are proofs that this philosopher was sensible, before Torricelli, of the weight of the air, and of its action for sustaining water in pumps, and tubes closed at the upper end. Amongst his Letters there is one dated in the year 1631, in which he accounts for the suspension of quicksilver, in tubes closed at top, by ascribing it to the weight of the column of air continued up to the clouds; the same way he explains, in the same letter, the pressure of a glass filled with hot air, upon a body, care being taken to close all communication with the external air. There are further proofs of this his opinion in several other of his letters. In one of them, not long after Galileo's Dialogues on Motion were published, Des Cartes rejects the pretended force of a vacuum, advanced by the Italian philosopher, and attributes the adhesion of two polished bodies solely to the pressure of the circumambient atmosphere. Lastly, in a letter wrote soon after that just mentioned, speaking of watering pots wherein the fluid is retained by closing the top orifice, "The water," says he, "is not retained in the vessel by a horror vacui, but by the weight of the air." And in another letter, he puts in a claim to the idea of the Puy-de-Dome experiment. After having desired of M. de Carcavi to inform him of the success of that experiment; which the public rumour had advertised him to have been made by M. Pascal himself, "I had reason," says he, "to expect this from him, rather than from you, because I first proposed it to him two years ago, assuring him at the same time, that although I had not tried it, yet I could not doubt of the consequence; but as he is a friend of M. Roberval, who professes himself no friend to me, I suppose he is guided by that gentleman's passions."

It will not be improper in this place to say something of Francisus Linus his hypothesis, whereby he pretends to solve the phenomenon of the

suspension of the quicksilver in the Torricellian experiment. His principles are these:

1. That there is an inseparability of bodies, so that there can be no vacuities in *rerum natura*.

2. That the deserted part of the tube is filled with a small film of quicksilver, which being taken off from the upper part of it, is both extenuated and extended through the seeming vacuity.

3. That by this extended film or rope, as he calls it, of dilated quicksilver, the rest of the quicksilver in the tube is suspended, and kept up from falling into the reservoir.

4. That this funicle or rope is exceedingly rarefied and extended by the weight of the pendent quicksilver, and will, upon removal of that violent cause which so holds it, recontract itself into its former dimensions again, and so draw up what body severer it has hold of along with it; as the effluvia of an electric body, upon its retreat, plucks up straws or any other thing with it, that it is able to wield.

5. That this extension of the film of quicksilver is not indefinite, but hath a certain limit beyond which it will not be stretched; and therefore if the tube be of an exceeding great height, the quicksilver will rather part with another film and extend that, and so a third or fourth, till it comes to the standard of 29 inches, where it rests, having not weight nor power enough to separate another film from it.

These are his principles; and to give a taste of the application of them, we shall add, that his reason why the quicksilver in a tube under 29 inches descends not all, is this; because it sticks with its uppermost surface so close to the top of the tube, that there is not weight enough to break that adhesion; the reason whereof is, because there is nothing to succeed in the room of the descending quicksilver, and therefore it firmly sticks there, *ne daretur vacuum*.

In longer tubes it falls to that standard, because then the greater weight of quicksilver is able to break that contiguity or adhesion, and therefore the uppermost surface of the quicksilver being sliced off, is dilated into a thin column or funicle, which supplies that seeming vacuity.

For the positive arguments to avouch his principles by, Linus has none at all; and only what he fetches *a posteriori*, from his commodious solution of difficulties, and solving the phenomena better than others have done. This is the funicular hypothesis, and the only one we have met with that pretends to account for the phenomena, by taking off the excess of gravitation of the quicksilver in the tube.

Thus much then may be said, that nature either suspends her settled laws for the production of these

these phenomena, or that there is some additional pressure communicated to the quicksilver in the vessel, which can be no other, as has been proved, than the pressure of the air which is contiguous to it; or lastly, that the excess of pressure from the quicksilver in the tube, is by some way or other, which we cannot discover, taken off, or rendered ineffectual.

It is unreasonable to imagine that nature should forsake her wonted paths on so trifling an occasion: it is certain we have no precedents to warrant such a suspicion. When the schoolmen say, nature abhors a vacuum, they must mean by nature, if they mean any thing, either the Author of all created beings, or the creatures themselves; if they would be understood in the first sense, they unavoidably charge Omniscience itself with incogitancy, supposing him to have created the world as continually to stand in need of miracles for its preservation; it being in their own power, as often as they please to make a trifling experiment, to put him to the necessity of interposing to hinder a vacuum. If they mean by nature the creatures themselves, then they must of necessity fall into another absurdity, whilst they suppose brute matter to be intelligent, and to put itself in action in pursuit of some determinate end. This we presume may be sufficient to expose that gross opinion concerning a *fuga vacui*, supposing it could account for the experiments, which it cannot do by any means.

It must be confessed, that Aristotle himself does somewhere assert the gravitation of the air; and to prove his assertion, he appeals to the experiment of a bladder full blown; which, says he, weighing more than when it was flaccid, is a manifest token of the weight of the air contained in it. But it is certain, however unreasonable it may seem, that his followers departed from their master, by asserting the contrary for several ages together.

Galilæo seems to be one of the first who discovered the specific gravity of the air, by different experiments. But the first experiment of this nature, which was generally taken notice of, was that of Mersenne.

He procured to himself on æolipile, or hollow globe of brass, with a very slender neck. See **ÆOLIPILE**. This he placed in the fire till it became red-hot, and immediately weighed it by a balance whilst it remained so. Afterwards he let it cool, and then weighed it again; and finding its weight to be greater than before, he concluded that the excess was the weight of the air which had been expelled by the heat, and had been permitted to return again upon the cooling of the globe. Thus he was satisfied that the air was a ponderous body; but in what measure it was so, he could not, by this experiment alone, determine. He therefore repeated the trial again, and found the weight of the globe when it was red-hot to be

the same as before. Then he placed the neck of it under water, and suffered it to cool in that posture; which being done, he found his globe to be almost filled with water; and knowing the bulk of that water to be the same with the bulk of the air which was expelled by the heat, upon weighing that water and comparing its weight with the weight of the air found by the former experiment, he concluded the specific gravity of air to be about 1300 times less than the specific gravity of water; whereas, by the experiments of Galilæo, it came out but 400 times less. If we take a mean between these two, we must say it is 850 times lighter; and this agrees very well with later and more exact observations.

Mr. Cotes always found the proportion of water to air, to be between the proportions of 800 and 900 to 1; but it generally approached somewhat nearer to 900.

Mr. Hauksbee took a bottle which held more than three gallons, and of a form something oval, which figure he chose, for the advantage of its more easy libration in water. Into this bottle he put as much lead as would serve to sink it below the surface of the water. And the reason why he chose rather to have the weight of lead inclosed within the bottle, than fixed any where on the outside, was, to prevent the inconveniencies which, in the latter case, must needs have arose from bubbles of air: for these bubbles would have inevitably adhered to, and lurked in great plenty about the body of the weight, had it been placed on the outside, which must have caused some errors in the computations of an experiment that required so much exactness and nicety. These things thus provided, the bottle containing common air closed up, was by a wire suspended in the water, at one end of a very good balance, and was counterpoised in the water, by a weight of $358\frac{1}{2}$ grains in the opposite scale. Then being taken out of the water, and screwed to the air-pump, in five minutes time it was pretty well exhausted, the mercury in the gage standing at near $29\frac{1}{2}$ inches: after which, having turned a cock that screwed both to the bottle and the pump, and so prevented the air's return into it again; it was taken off from the pump, and suspended as before, at one end of the balance in the water. And now the weight of it was but $175\frac{1}{2}$ grains; which, therefore, subtracted from $358\frac{1}{2}$ grains (the weight of the bottle with the inclosed air, before it had been applied to the air-pump) gave, for the difference, 183 grains; which difference must consequently be the weight of a quantity of air, drawn from the bottle by the pump. Having thus determined the weight of the exhausted air, the cock was opened under water, upon which the water was at first impelled with a considerable violence into the bottle (though this force abated gradually afterwards) and continued,

to rush in, till such a quantity was entered, as was equal to the bulk of the air withdrawn. And then the bottle, being examined by the balance again, was found to weigh 162132 grains; from which subtracting $175\frac{1}{2}$ grains (the weight of the bottle with the small remains of included air, after it was taken from the air-pump) there remains 161956 $\frac{1}{2}$ grains, for the weight of the mass of water, equal in bulk to the quantity of air exhausted. So that the proportion of the weights of two equal bulks of air and water, is as 183 to 161956 $\frac{1}{2}$, or as 1 to 885.

There are two things particularly observable in this experiment. First, that in making it after this manner, one needs not be very solicitous about a nice and accurate exhaustion of the receiver; the success of the experiment does not at all depend upon it, for to what degree soever the exhaustion be made, it must still answer in proportion to the quantity taken out. Neither can any more water possibly enter into the receiver, than what will just supply the place, and fill up the room, deserted by the exhausted air. Secondly, the season of the year is to be considered in this experiment. He made it in the warm month of May, the mercury in the barometer standing at the same time at 29.7 inches. From whence it is reasonable to conclude, that a sensible difference would arise, were it to be tried in the months of December or January, when the state and constitution of the air is usually different from what it is in the foregoing months. Dr. Jurin therefore recommends a mean temperature of the air to make the experiment in, and believes that the weight of air would then be found to that of water, nearly as 1 to 800.

Muschenbroeck says he has sometimes found the proportion to be as 1 to 606; and observes, that in making the experiment in different years and seasons, he met with a continual difference; but that in experiments made in Europe, the limits will never be wider than 1 to 606, and 1 to 1000.

The laws of the air's gravitation and pressure, as a fluid, must be the same as those of other fluids; and consequently its pressure must be proportional to its perpendicular height. See FLUID.

Moreover this consequence is confirmed by experiments. For if the Torricellian tube be carried to a more elevated place, where the column of air is shorter, the column of quicksilver which it sustains will also be shorter, falling about a quarter of an inch upon an ascent of an hundred feet. On this principle depends the structure and use of the barometer. See BAROMETER.

And from the same principle it likewise follows, that air, like all other fluids, presses equally in all directions. A proof whereof is, that we see soft substances endure its pressure without any alteration of their form, and brittle ones without break-

ing, notwithstanding the pressure of the column of air on such bodies is equal to that of a column of quicksilver of 30 inches, or to one of water of 33 or 34 feet: but if the pressure be removed or diminished on one side, the effect of it on the other side will be instantaneously perceptible.

From the weight and fluidity of the air conjointly considered, many effects and uses of it may be easily deduced. By the combination of these two qualities, it envelops the earth and all bodies upon it, compresses and unites them with a considerable force. The specific gravity of air being known, the weight of a cubic foot of it will also be known. For if a cubic foot of water weighs 62 pounds, a cubic foot of air will weigh about the 800th part of 62 pounds; whence may be concluded the weight of any certain quantity of air. Likewise the force with which the air compresses all terrestrial bodies, may be determined; for it is evident, that such pressure is the same as if the whole globe were covered with water about 33 feet high. Now a cubic foot of water weighing 62 pounds, 33 feet will weigh 33 times 62 pounds, or about 2046 pounds; and as the earth's surface contains about 5568313666502400 square feet, 2046 times this great number must be taken to get nearly the weight reduced to pounds, with which the air compresses our globe. Now the effect of such a pressure must be very considerable. It prevents, for example, the arterial vessels of plants and animals, from being excessively distended by the impetuosity of the juices, which circulate in them, or by the elastic force of the air, of which a considerable quantity is intermixed with the blood. From air thus mixed with the blood, it is that when, by means of a cupping-glass, the pressure of the external air is in a great measure taken off from one part of the body, that part is distended, and causes an alteration in the circulation of the fluids in the capillary vessels.

The same cause hinders the fluids from transpiring, and escaping through the pores of their containing vessels, as it happens to travellers in ascending high mountains: they find themselves more and more relaxed, as they advance upwards; and at length are seized with spitting of blood, or other hæmorrhages, because there is not sufficient pressure of air on the pulmonary vessels. The same happens to animals shut up in the receiver of an air pump; whilst the air is pumping out, they tumify, vomit, flaver, sweat, and render their urine and other excrements. See VACUUM.

To the same two qualities of the air, weight, and fluidity, is owing the mixture of bodies contiguous to one another, especially fluids. And divers liquids, as oils and salts, which readily mix of themselves in air, but will not mix at all in vacuo.

Also, in consequence of the same two qualities, the

the air determines the action of one body upon another. Thus fire, which burns wood, is put out, and its flame is dissipated, if the air be withdrawn; because then there is nothing that is able to apply the particles of the fire against those of the combustible substance, and hinder the flame from dissipating. The same happens to gold dissolving in aqua regia; the menstruum ceasing to act on the metal as soon as the air is drawn off: and it is in consequence of this determining faculty of the air, that Dr. Papin invented the *digestor*, which bears his name. See DIGESTER.

On the same account it is, that on the tops of very high mountains, such as the Pic of Teneriffe, substances of the most poignant flavour, as pepper, ginger, salt, spirit of wine, &c. are in a manner insipid; for through want of an agent sufficient to apply their particles on the tongue, and cause them to enter its pores, they are rarefied and dispersed away by the mere warmth of the mouth. The only substance found to retain its relish there is Canary-wine, and this in virtue of its unctuous quality, which makes it adhere closely to the palate, and hinders it from evaporating.

The same principle of gravity produces also, in part, winds, which are nothing else but air put in motion through some alteration in its equilibrium. See WIND.

Another quality of the air, from whence arise a multitude of effects, some already mentioned, is its elasticity, whereby it yields to the impression of other bodies, by contracting its volume; and restores itself again to the same extent, by repelling or weakening the cause which had contracted it. This elastic force is one of the most distinguishing properties of air; the two other properties before spoken of, being common to it with other fluids.

An infinity of proofs evince the existence of this faculty in air. If we press, for example, a blown bladder with the hand, we find a sensible resistance from the included air; and upon ceasing the pressure, the part compressed immediately is restored to its former size.

On this property of the air depends the construction and use of the air pump. See AIR PUMP.

Every particle of air makes a continual effort to dilate itself, and thereby acts forcibly against all neighbouring particles, which also exert the like force; but if the resistance happens to cease, or to be weakened, the particle instantly becomes prodigiously rarefied. This is the reason why little glass balls, placed under the receiver of an air pump, do, upon pumping out the air, burst asunder by the force of the air which they contain. If a close flaccid bladder, containing but a small portion of air, be put under the receiver, it will tumify as the air is exhausted, and at length ap-

pear full. The same thing happens if the flaccid bladder be carried to the top of a very high mountain.

The same experiment shews very manifestly, that the elasticity of solid bodies is very different from the elastic virtue of air, and that elastic solid bodies are dilated after a very different manner from air. For when air ceases to be compressed, it not only dilates, but then occupies a far greater space, and exists under an immensely greater volume than before; which is never observed in solid elastic bodies, those resuming only the figure they had before they were compressed.

The air, such as that near the surface of the earth, is rarefied in such sort, that its volume is ever in the inverse ratio of the weight which compresses it; that is, if air pressed by a certain weight occupies a certain space, the same air pressed by a weight which is but the half of the former, will occupy a space double that which it occupied in the former case. Boyle and Mariotte established this rule from experiments. The same rule takes place in compressed air, as Mariotte has also shewn. However, this rule is not to be admitted as scrupulously exact; for when air is very forcibly compressed, and reduced to a bulk four times less than before, the effect does not answer precisely to Mariotte's rule; the air, in this case, begins to make a greater resistance, and requires a stronger compression, that is, a greater weight than according to the rule; and a moderate degree of attention will shew the impossibility of the rules being exactly true: for supposing the air to be so strongly compressed, that all its particles come in contact with one another, so as to form but one solid mass, it can be compressed no farther; since bodies are impenetrable. It is no less evident, that air cannot be rarefied in *infinitum*, and that its rarefaction must have its limits; whence it follows, that the rule of the rarefaction being in the inverse ratio of the compressing weight, cannot again be absolutely exact; since, according to this rule, to any given degree of the air's rarefaction, a corresponding weight might be assigned which would hinder that rarefaction from becoming greater: but when the air is rarefied the most that is possible, it is not charged with any weight at all, and yet it occupies a certain space.

We know not how to assign any precise limits to the elasticity of the air, nor to destroy or any ways alter it. Mr. Boyle made a multitude of experiments, to see if he could weaken the spring of air extremely rarefied in the receiver of his air pump, by keeping it a long time compressed by so great a weight as it is astonishing to think it could endure a single moment; and, after all, he could perceive no sensible diminution of the elasticity. And M. de Roberval having left an air gun charged full 16 years; it, upon being discharged, propelled the

ball with as much force as if the air had been newly condensed.

However, Mr. Hauksbee undertook to prove, by an actual experiment, that the spring of the air may be so far disconcerted by a violent pressure, as not to be able to restore itself till after some time. To this end he took a strong brass condensing engine, into which he poured half a pint of water; then, the upper part being strongly screwed on, he threw into it with a syringe three or four atmospheres of air, as near as he could guess; and, in this state, he suffered it to remain something more than an hour. Then letting out as much of the air, by taking off the syringe, as would readily go away, he presently screwed on its room a box of leather collars, through which there passed a small glass tube, open at both ends, whose lower orifice was plunged under the surface of the included water. After this, in a very little time, he found the water had ascended very near a foot in the tube, and it continued rising till it had reached near fifteen inches.

He concluded from hence, that the elastic force of the air had been weakened for some time; for had it remained the same as at first, the whole air would have escaped from the vessel upon opening it; whence it follows, according to Mr. Hauksbee, that what air was left in the vessel, became after some time rarefied, and caused the water to rise in the glass tube.

But is it not possible, that a considerable quantity of the air might have entered into the water, since the air which rested thereon was three or four times more compressed than the natural, and was not in a condition to extricate itself till after some time? so that what of it could freely escape, did in effect get out of the vessel whilst that which had penetrated the water required time to work its way back again. M. Musschenbroek having poured quicksilver into a tube eight feet long, one of whose ends was recurved and closed up, by which the air in the recurved end was compressed, sealed the other end hermetically, marking the degree of the temperature of the air at that time: from which time, he says, he constantly observed that the mercury kept at the same height in the tube, when the air had the same degree of warmth as when the experiment was first made; on the contrary, when the air was warmer, the quicksilver rose in the tube; whence it seems to follow, that the compression of the air does not hurt its elasticity. However, it cannot be denied that Dr. Hales has proved the possibility of the thing, by kindling sulphur in a glass full of air; and, perhaps, there are a great number of exhalations capable of producing the same effect.

It is plain, that the weight or pressure of the air does not at all depend on its elasticity, and that it is neither more nor less heavy than if it were not

at all elastic. But from its being elastic, it follows that it is susceptible of a pressure, that reduces it to such a space, that the force of its elasticity, which reacts against the pressing weight, is exactly equal to that weight. Indeed the true law of the elasticity is, that it increases in proportion to the density of the air, and that its density increases in proportion to the forces which compress it. But there is a necessary equality between action and reaction; that is, the gravity of the air which effects its compression, and the elasticity of it which gives it its tendency to expansion, are equal. See DENSITY, and REACTION.

Thus the elasticity increasing, or abating, generally in proportion to the augmentation or diminution of the density; that is to say, as the spaces between the particles of the air increases or diminishes; it matters not, whether or no the air be compressed or confined within a certain space, by the weight of the atmosphere, or by any other cause: it is sufficient, that it tends to expand itself with a force equal to that of the cause which compresses it. For this reason, if such air as is near the earth, be inclosed in a vessel, so that it can have no communication with the external air, the pressure of such inclosed air against the inward surface of the vessel, will be exactly equal to the pressure of the atmosphere on its outside. Hence we see, that the air of a very close room sustains the quicksilver in the barometer, by its elastic force, at the same height, as the weight of the whole atmosphere would do. See ELASTICITY.

According to this principle the air, by proper contrivances, may be condensed; and upon it, is founded the construction of the air gun. See CONDENSER, and AIR GUN.

To what degree air is susceptible of condensation, by compression, is not certainly known. Mr. Boyle found means of rendering it thirteen times denser, by compressing it, than it was before: others assert, that they have known it reduced to a sixtieth part of its common bulk. Dr. Hales made it thirty-eight times more dense, by means of a press: but by causing water to freeze, in a grenade or hollow bullet of cast iron, he reduced air to $\frac{1}{11}$ of its volume, so that it must have been above twice as specifically heavy as water: and as water is not compressible, it follows from this experiment that the aerial particles must be of a nature very different from those of water; since, otherwise, it would be impossible to reduce air to a volume above 800 times less than its common one; and indeed Dr. Halley, in the Philosophical Transactions, says, in consequence of some experiments made in London, and others at Florence in the Academy del Cimento, it may be safely affirmed that no force is capable of reducing air into a space 800 less than that which it naturally occupies near the surface of the earth.

Air, in virtue of its elastic force, is dilatable to a very

a very amazing degree. Fire has the property of rarefying it very considerably; and, through such rarefaction, air produces the same effect as if its elastic force were increased; and thus it endeavours to extend itself in all directions. On the contrary, cold condenses it, and it may be said, in that circumstance, to have lost of its elastic force. The force of heated air may be proved by confining it close in a thin glass phial, hermetically sealed, and set on a fire; the air then is rarefied so forcibly as to burst the phial in pieces, with a considerable noise. Likewise a bladder half full of air, held near the fire, will not only become tumid by the swelling of its air, but will also burst asunder. M. Amontons found that air made as hot as boiling water, acquired a force which is to that of the weight of the atmosphere, as 10 to 33, or as 10 to 35; and that the result was alike, whether a greater or a less quantity of air were made use of in the experiment.

Mr. Hauksbee observed that a portion of air, inclosed in a glass tube, when it began to freeze, formed a volume which was to that of the same quantity of air in the greatest heat of summer here in England, as 6 to 7.

M. Amontons asserts, that the elasticity of such air as he calls temperate, is to the elasticity of air of the same heat as boiling water, as 3 to 4 nearly, or, more accurately, as 55 to 73: but Dr. Daniel Bernoulli, from experiments of his own, says he has found that the elasticity of the hottest air at Peterburg, in the midst of summer, has not so much elasticity as M. Amontons ascribes to temperate air; and is firmly persuaded, that even under the line itself, the air can never acquire such a heat; and, from a course of observations, he collects that the greatest variations of the heat of that country, are contained between the terms of 3 and 4; believing that the heat of air, whose elasticity is equal to three-fourths of the elasticity of air as hot as boiling water, must be in a manner intolerable to an animal body.

When air is at liberty, and clear of the cause that compressed it, it ever assumes a spherical figure in the interstices of the fluids in which it is lodged. This is evident in liquors placed in the receiver of an air pump, by exhausting the air; for at first there appears a multitude of extraordinary small bubbles, like grains of fine sand, dispersed through the fluid mass, and rising upwards; and as more air is pumped out they enlarge in size, but still continue round. If a plate of metal be immersed in the liquor, upon pumping, its surface will be seen covered over with small bubbles, which are nothing but the air which adhered to it, now expanding itself.

No means have been neglected to discover how far air will be dilated, when entirely free: but the enquiry is subject to great difficulties; because our

atmosphere is composed of divers elastic fluids, which have not all the same force; consequently to know how far air that is pure, and without any mixture, can be dilated, it will be first necessary to procure pure air, which is no easy matter. It must next be known in what vessel, and how, such air must be placed, that its particles may be kept separate, so as not to act upon one another: indeed many philosophers have despaired of solving the problem; nevertheless we may conclude, with Musschenbroek, from some coarse experiments, that the air near the surface of our globe, may expand so far as to occupy a space four thousand times as great as it does in its ordinary state.

Mr. Boyle, from several experiments, found it dilated nine times, from others 31 times, then from 60 to 150 times; and lastly, as he says, 8000, 10000, and even 13679 times beyond its first bulk; and this purely from its innate expansive virtue, without having any recourse to fire.

On this principle depends the construction and use of the manometer. See MANOMETER.

From the several before cited experiments, it appears how greatly Aristotle was mistaken, when he pronounced that air ten times rarefied, changes its nature, and becomes fire.

Amontons makes the rarefaction of the air to arise from the fire which it contains; so that by augmenting the degree of heat, the rarefaction will be increased to a far greater degree than it can possibly be by a spontaneous dilatation.

From this principle he deduces the construction and use of the thermometer. See THERMOMETER.

He first of all discovered that the more dense the air is, the more it will be dilated by the same degree of heat: in consequence of which discovery he wrote a tract to prove, that the spring and weight of the air combined with a moderate degree of heat, may be sufficient to produce even earthquakes, and other most violent commotions in nature. See EARTHQUAKE.

Dr. Hales made many curious and accurate experiments with regard to measuring the great quantities of air that were raised, or generated, or absorbed, by the fermentation arising from the mixture and variety of solid and fluid substances, whereby he could easily estimate the surprising effects of fermentation on the air.

He put into the bolt-head *b*, (Plate I. fig. 6.) the ingredients, and then run the long neck of the bolt-head into the deep cylindrical glass *ay*, and inclined the inverted glass *ay*, and bolt-head almost horizontal in a large vessel of water, that the water might run into the glass *ay*: when it was almost up to the top *a*, of the bolt-head, he then immersed the bottom of the bolt-head, and lower part of *y* of the cylindrical glass under water, raising at the same time the end *a* uppermost. Then

Then before he took them out of the water, he set the bolt-head, and lower part of the cylindrical glass *ay*, into the earthen vessel *xx* full of water, and having lifted all out of the great vessel of water, he marked the surface *z* of the water in the glass *ay*. If the ingredients in the bolt-head, upon fermenting, generated air, then the water would fall from *z* to *y*, and the empty space *zy*, was equal to the quantity of air generated.

But if the ingredients upon fermentation did absorb or fix the active particles of air, then the surface of the water would ascend from *z* to *n*, and the space *zn*, which was filled with water, was equal to the bulk of air, which was absorbed by the ingredients, or by the fume arising from them. To make an estimate of the quantity of air absorbed, or fixed, or generated, by a burning candle, burning brimstone or nitre, or by the breath of a living animal, &c. he first placed a high stand or pedestal on the vessel full of water *xx*; (Plate I. fig. 7.) which pedestal reached a little higher than *zz*: in this pedestal he placed the candle, or living animal, and then whelmed over it the large inverted glass *zzaa*, which was suspended by a string, so as to have its mouth *rr*, three or four inches under water; then with a syphon he sucked the air out of the glass vessel, till the water rose to *zz*. But when any noxious thing, as burning brimstone, aqua-fortis, or the like were placed under the glass; then by affixing to the syphon the nose of a large pair of bellows, whose wide sucking orifice was closed up, as the bellows were enlarged they drew the air quickly out of the glass *zzaa*, through the syphon; the other leg of which syphon he immediately drew from under the glass vessel, marking the height of the water *zz*. When the materials on the pedestal generated air, then the water would subside from *zz* to *aa*, which space *zzaa*, was equal to the quantity of air generated: but when on the contrary, they destroyed any part of the air's elasticity, then the water would rise from *aa* (the height that he at first sucked it to) to *zz*, and the space *zzaa*, was equal to the quantity of air whose elasticity was destroyed.

When the matter for trying the experiments was phosphorus, gunpowder, nitre, &c. the Doctor usually fired them on the pedestal by means of a burning glass, which collected the sun's rays into a focal point on the matter to be fired. He likewise made an estimate of the quantity of air which arose from any body by distillation, or fusion. He first put the matter intended to be distilled into a small retort *r*, (Plate I. fig. 8.) and then at a cemented fast to it the glass vessel *ab*, which was very capacious at *b*, with a hole in the bottom; he bound a bladder over the cement, which was made of tobacco-pipe clay and bean flower, well mixed with some hair, tying over the whole four

small sticks, which served as splinters to strengthen the joint: matters being thus prepared, holding the retort uppermost, he immersed the bolt-head into a large vessel of water to *a*, the top of the bolt-head; as the water rushed in at the bottom of the bolt-head, the air was driven out through the syphon; when the bolt-head was full of water to *z*, then he closed the outward orifice of the syphon with the end of his finger, and drew the other leg out of the water at the same time, by which means the water continued up to *z*, and could not subside. Then he placed under the bolt-head while it was in the water, the vessel *xx*, which done, he lifted the vessel *xx* with the bolt-head in it, out of the water, and tied a wax thread at *z*, to mark the height of the water; and then approached the retort gradually to the fire, taking care to screen the whole bolt-head from the heat of the fire. As the matter distilled, all, except the air, went down into the water in the bolt-head and vessel, the air that was generated, or destroyed, would be seen by causing the surface of the water in the bolt-head to stand below or above the point *z*, as at *y*, when all was set aside and cold. For if the body distilling generates air of an elastic quality, that added to the former will not permit the water *y*, to rise so high as *z*, and the space between *z* and *y* below, will shew how much air was produced from its fixed state: but if when all is cold, the surface of the water *y* be seen above the point *z*, it then shews that the distilled body did destroy, that is, imbibe or absorb a part of the natural air above *z*; and the space between *z* and *y* filled with water, will shew what quantity was changed from a repellent elastic to a fixed state. This quantity of generated or absorbed air, it is easy to measure in cubic inches, by stopping the end of the bolt-head with a cork, and then with a quantity of water of a known weight, to fill it first to *z*, and afterwards to *y*, and the difference of weight in the two bulks of water gives the number of cubic inches, from a table of specific gravities.

After the Doctor has given a description, as above, of his instruments and method of making experiments, he then gives the event or result of a great number which he made with great accuracy. He found that a cubic inch of hog's blood, distilled to dry scoria, produced 33 cubic inches; that a cubic inch of tallow distilled, produced 18 cubic inches of air; that half a cubic inch of the tip of a fallow deer's horn, produced 117 cubic inches, or 234 times its own bulk in air.

A dram of volatile salt, of sal aromatic distilled, generated no air, but absorbed $2\frac{1}{2}$ cubic inches. Phosphorus fired in a small receiver, expanded into a space equal to 60 cubic inches, and absorbed 28 cubic inches of air. He likewise found that from $\frac{1}{2}$ an inch of oak fresh cut from the growing tree,

was generated 108 cubic inches of air; and that from 135 grains of thin shavings taken from the same piece of oak, and laid before the fire 24 hours, it evaporated 24 grains of moisture in that time. From 388 grains of Indian wheat, which grew in his own garden, but not come to full maturity, was generated 270 cubic inches of air, the weight of which air was 77 grains, which is one fourth of the weight of the wheat. He likewise adds, that from a cubic inch, or 318 grains of pease, was generated 396 cubic inches of air, or 113 grains, which is something more than one third of the weight of the pease. The Doctor also found great plenty of air incorporated into the substance of vegetables, which by the action of fermentation, is roused into an elastic state, as is evident from many experiments, and which may be seen at length in the Doctor's treatise of the Analysis of the Air.

AIR, in medicine, makes one, and not the least powerful, of the non-naturals; as upon it the very life of animals depends.

It is susceptible of different qualities; hot, moist, cold, dry, serene, pure, and temperate. It is subject to variations, more or less sudden, and to be mixed with impure, corrupted, contagious, metallic, sulphureous exhalations, which are all prejudicial to health. The best quality of the air is to be pure and sweet, void of all bad exhalations, neither too hot, cold, dry, nor moist.

The sudden changes of the air are inevitable and dangerous; whence proceed a great number of diseases, which reign in the spring and autumn, towards the approach of winter. Hospitals, camps, places where lead is melted, and the earth just thrown up, are generally unhealthy, on account of the bad exhalations. Lighted charcoal, in a close place, fills the air with sulphureous particles, which are unwholesome, and sometimes kill the strongest persons.

Too hot an air disposes to malignant fevers; if it be without moisture, it produces dry and putrid fevers. Agues are epidemic in the fens of Cambridgeshire, the hundreds of Essex, and in some parts of Kent, on account of the vapours, which weaken the fibres of the body, and obstruct the pores of the skin; besides, a cold and moist constitution of the air produces coughs, distillations, and rheumatic pains.

Hætic and consumptive people are in great danger, both in very hot and in very cold weather. When the passage through the pores of the skin is stopped by cold, the patient is either apt to fall into a looseness, or to have his legs swelled, and the asthmatic symptoms increased.

AIR, in mythology, was worshipped by the pagans, under the names of Jupiter and Juno; the former representing the superior and finer part

of the atmosphere, and the latter the inferior and grosser part.

AIR, in painting and sculpture, denotes the manner and very life of action; or, it is that which expresses the disposition of the agent. See ACTION.

Some use the word to signify the gesture or attitude of a figure.

AIR, in music, implies the melody proper for songs, odes, &c. being usually quick and lively.

The term is sometimes used to signify the fongs themselves, called by the Romans, *æra*, whence the word in this acceptation is derived.

AIRS, in the menage, signify the artificial motions of taught or menaged horses; such as the demi-volt, curvet, capriole, &c.

Some extend the term to the natural paces of a horse, as walking, trotting, galloping; but this is not a proper application of the word, and is accordingly never used in the latter sense by the best writers.

AIR-BLADDER, a vesicle found in the bodies of all fishes, except those of the cartilaginous and cetaceous kinds. It is vulgarly called the swim, or swimming bladder.

By the assistance of this bladder, which is always more or less replete with air, the fish is enabled to sustain its body at any depth. When the fish is near the bottom, the great weight of the incumbent water compresses its body, or rather the inclosed air-bladder, till the whole fish becomes equiponderant with an equal bulk of water. In the middle of the fluid, where the pressure is less, the air-bladder expands; thereby increases the bulk of the fish, without adding any thing to its weight, till it here also becomes equiponderant with an equal bulk of water; and in this manner the air-bladder expands, as the fish rises nearer the surface, and by that means sustains it in any depth.

There is however no doubt but fishes have a power of expanding and compressing the air-bladder, exclusive of the weight of the water, and by that means of rising or sinking at pleasure.

Some fishes have only a single air-bladder; some a double one; and in others it is triple, or divided into three cells. Fishes which lie grovelling at the bottom, have no air-bladders; and it is remarkable, that if the air-bladder be either pricked or burst, in fishes naturally furnished with it, they immediately sink to the bottom; from whence they can never rise themselves.

AIR-GUN, a pneumatic machine for exploding bullets, &c. with great violence. See GUN.

Magazine AIR-GUN. See GUN.

AIR-JACKET, a particular kind of leathern jacket, in which there are a great many bags made of leather, which are interperfed round the jacket,

jacket, and have communication with each other: to one of these bags, which are in the form of bladders, is neatly fitted a leather tube or pipe, having a brass stop-cock, air tight, fitted to the extremity; therefore by blowing through this pipe, the bags are filled with air, and by turning the stop-cock, it is confined in the bladders. As the human body differs but very little in specific gravity from water, it will be easy to conceive, that a few of these bladders or bags will reduce them not only to an equal gravity bulk for bulk, but even make it impossible to sink while the machine remains air tight; but if it should, in a length of time, emit the air through the pores of the leather, or by means of any other small imperfection, the pipe and stop-cock is so contrived, that the person wearing this jacket may reinstate the deficiency of the bladders while on the water with great ease. Care must be taken that the bags be wet, before the air is blown into them, otherwise it will immediately escape through the pores of the leather.

AIR-PUMP, in pneumatics, a machine for exhausting the air out of a proper vessel, called a receiver, in order to discover its chief properties and effects on natural bodies. This instrument was invented by Otto Guericke, consul of Magdeburgh, some time before the year 1654; for then this gentleman being employed in a public negotiation at Ratibon, shewed this instrument to the emperor, and some other princes there present: and in the year 1672, he described his instrument, with a narrative of his trials with it, in a book called, *Experimenta nova Magdeburgica de Vacuo Spatio*.

The first was attempt afterwards executed with great improvements by Dr. Hook, at the instance of Mr. Boyle; and further perfected by Dr. Rapin, Mr. Hauksbee, and lastly, by Mr. Smeaton, F.R.S.

The air-pump commonly made use of now, is that represented by Plate II. fig. 3. where AA are the two brass barrels, in which the pistons CC move up and down. The brass tube or pipe marked HH, is called the swan's neck, through which the air passes from under the receiver OO, by a small hole K, in the middle of the brass plate II, on the top of the pump, to a brass piece in the box DD, which being perforated lengthwise to the middle point under each barrel, transmits the air through a bladder-valve to be pumped out. The mercurial gauge which communicates with the receiver, is marked LLL. The stop-cock N, serves to readmit the air, when there is occasion. B is the handle or winch for turning or working the pump. GG are two pillars supporting the frame of the pump-wheel, which is screwed upon them by the two nuts EE.

The uses of the other parts will readily be comprehended by inspection of the figure.

It is usual to make the valves in air-pumps of bladder; but it will be found to answer the purpose much better to make them of thin neat's skin: for oil is found by experience to harden those made of bladder, which are very apt to crack, and to be out of order; when, on the contrary, the neat's skin valves are kept supple and pliant by the oil, and seldom want repairing. It is likewise customary to use wet leather to place the receiver upon, &c. but we would recommend, that a proper mixture of sweet-oil and bees-wax be melted together over a slow fire, and the leather made supple with this mixture while luke-warm, which will, when cold, be found to answer the purpose much better than wet leather, which greatly damages the works of the pump.

Description of the portable AIR-PUMP. This pump is described by Plate II. fig. 4. where AB is the head or part containing the wheel, which alternately rises and depresses the pistons C, D, in the barrels E, F, which are strongly pressed down by the part AB, supported by two the pillars G, H, fixed into the bottom IKL of the machine. On this bottom stands the receiver MN, on a large smooth plate, in the middle of which is a hole by which the air passes out of the receiver into a small tube on the under part of the frame, and goes to the piece O, which communicates with the perforated brass-piece on which the barrels stand, and from which they receive the air to be exhausted: on the middle part of this brass-piece, is a perforation, over which is placed a small receiver PQ, and under it a basin of mercury R, in which a small tube RS, hermetically sealed at one end, and filled with quicksilver, is inverted, and consequently, as the small receiver PQ, is exhausted, together with the large one MN, the approach of the vacuum will be shown by the falling of the quicksilver in the tube RS: by means of a stop-cock at T, the air is again let into the receiver.

Description of Mr. Smeaton's AIR-PUMP. The principal causes of imperfection in the common air-pumps arise, 1st, from the difficulty in opening the valve. 2dly, from the pistons not fitting exactly when put close down to the bottom, thereby leaving a lodgement of air. To avoid these inconveniences as much as possible, instead of one small valve this pump has seven large ones, all of equal size and shape, one in the center with six round it, so that the bladder valve is supported at proper distances, by a kind of grating made by the solid parts between the holes: also the top of the barrel is shut up with a plate, having a collar of leathers in its middle, through which the rod that carries the piston moves. Thus the external air is

Fig. 4. Portable Air pump.

is prevented from pressing upon the piston, and the air which passes through the valve of the piston from below, may be discharged out of the barrel. There is also a valve applied to the plate at the top, which opens upwards; and thus the air in the lodgment under the piston, will evacuate itself so much more easily, as the pressure upon the piston valve will be less.

Mr. Smeaton found the usual gauges very unfit for measuring the expansion of the air, where accuracy is required: the following one does it to less than the 1000th part of the whole capacity. It is a bulb of glass, shaped almost like a pear, which holds about a pound of quicksilver, and is open at the lower end, with a tube at top, whose end is hermetically sealed. By a nice pair of scales, he found the proportion of weight a column of quicksilver of a certain length in the tube, bore to that which filled the whole vessel, and marked dimensions on the tube, answering each to $\frac{1}{1000}$ of the whole capacity. The gauge during the exhausting, is suspended in the receiver by a slip wire. When the pump has been worked as much as is judged necessary, the gauge is pushed down, till its open end is immersed in a cistern of quicksilver placed underneath. The air being let in, the quicksilver will be driven into the gauge, till the air remaining in it becomes of the same density with the external; and the expansion will be shewn by the number of divisions occupied by the air at top.

This pump is made to act likewise as a condenser at pleasure, by singly turning a cock; and will then shew the experiments of an air gun. See AIR GUN, and CONDENSER.

Explanation of the Figures relating to the Air Pump, in Plate III.

Fig. 3. Is a perspective view of the principal parts of the pump together.

A, Is the barrel.
B, The cistern, in which is included the cock with several joints.

C, The triangular handle of the key of the cock; which, by marks on its arms, shews how it must be turned, that the pump may produce the effect desired.

DH, The pipe of communication between the cock and the receiver.

E, The pipe which communicates between the cock and the valve, on the upper plate of the barrel.

F, The upper plate of the pump, which contains the collar of leathers *d*, and V the valve, which is covered by the piece *f*.

G I, The syphon gauge, which screws on and off, and is adapted to common purposes. It consists of a glass tube hermetically sealed at *c*, and furnished with quicksilver in each leg, which, be-

fore the pump begins to work, lies level in the line *a b*, the space *b c* being filled with air of the common density. When the pump exhausts, the air in *b c* expands; and the quicksilver in the opposite leg rises, till it becomes a counterbalance to it. Its rise is shewn upon the scale *L a*, by which the expansion of the air in the receiver may be nearly judged of. When the pump condenses, the quicksilver rises in the other leg, and the degree may be nearly judged of by the contraction of the air in *b c*; marks being placed at one-half and one-third of the length of *b c*, from *c*; which shew when the receiver contains double or treble its common quantity.

K L, A screw frame to hold down the receiver in condensing experiments, which takes off at pleasure, and is sufficient to hold down a receiver, the diameter of whose base is seven inches, when charged with a treble atmosphere; in which case, it acts with a force of about 1200 pounds against the screw frame.

M, A screw that fastens a bolt which slides up and down on that leg whereby the machine is made to stand fast on uneven ground.

Fig. 7. Is a vertical section of the barrel, cock, &c. where

A B, Represents the barrel.

C D, The rod of the piston, which passes through

M N, The plate which closes the top of the barrel.

K, The collar of leathers, through which the piston rod passes. When the piston is at the bottom of the barrel, the upper part of K is covered by the cap at D, to keep out dust, &c.

L, The valve on the upper plate, which is covered by the piece

O P, Which is connected with the pipe

Q R, Which makes the communication between the valve and cock.

C E, The piston and

E F F, The piston valve.

I I, Two little holes to let the air pass from the piston valve into the upper part of the barrel.

G G, The principal valve at the bottom of the barrel.

H H, A piece of metal, into which the valve G G is screwed, and closes the bottom of the barrel; out of which also are composed

S, The cock, and

T T, The duct from the cock to the bottom of the barrel.

W, The key of the cock.

X, The stem, and

V, The handle.

Fig. 6. Is a horizontal section of the cock, through the middle of the duct T T.

A B, Represents the size of the circular plate that closes the bottom of the barrel.

EFG, The body of the cock, the outward shell being pierced with three holes at equal distances, and corresponding to the three ducts HH, II, KK, whereof

HH, Is the duct that goes to the bottom of the barrel.

II, The duct that communicates with the top of the barrel.

KK, The duct that passes from the cock to the receiver.

LMN, The key, or solid parts of the cock, moveable round in the shell EFG. When the canal LM answers to the duct HH and KK, the pump exhausts, and the air is discharged by the perforation N. But the key LMN being turned till the canal LM answers to II and KK, the perforation N will then answer to HH; and in this case, the pump condenses. Lastly, when N answers to KK, the air is then let in, or discharged from the receiver, as the circumstance requires.

Fig. 4. Is the plan of the principal valve.

ABCD, Represents the bladder fastened in four places, and stretched over the seven holes IK, formed into an hexagonal grating, which may be called the honey-comb.

EFGH, Shew where the metal is a little prominent, to hinder the piston from striking against the bladder.

Fig. 5. Represents the pear gauge. It is open at A; BC is the graduated tube, hermetically closed at C, and suspended by the piece of brais DE, hollowed into a cylinder, and clasping the tube.

N. B. A pump of this kind, when clean and in order, has been found to rarefy the air above 2000 times; whereas the common ones, tried by this gauge, have not been found to exceed 150 times.

Theory of the Air Pump. Mr. Varignon in the *Memoires de Mathematique & de Physique*, for December 1693, gives a general theorem for finding the ratio of the density of the air in its natural state to that in the receiver, after a certain number of strokes of the piston in the barrel; which, if we put a = state of the natural air, x = the state after any number of strokes, c = the capacity of the receiver, b = the capacity of the receiver and barrel together; and d = number of strokes, we

shall have this proportion, $a : x :: \frac{d}{b} : \frac{d}{c}$. The truth

of which is evident, if we consider that each time the piston is thrust down to the bottom of the barrel and raised up again, that the air by its elastic spring will expand itself and fill up the cavity made by the piston; therefore, after each stroke of the piston in the barrel, the remaining air in the receiver and barrel will be to that in the receiver before, as the capacity of the receiver alone, to the capacity of the receiver and barrel together.

Suppose e, f, g, h , to be the logarithms of a, x, b, c . Then as $e : f :: gd : bd$, $\therefore e + bd = f + gd$, or $e - f = gd - bd$; where $gd - bd$ is the logarithm of the ratio of the air sought. In words, the logarithm of the ratio of the density of the air in its natural state to that in the receiver after the operation, is always equal to the product of the number of strokes of the piston, multiplied by the logarithm of the ratio between the capacity of the barrel and receiver together and the receiver alone.

Thus if the capacity of the receiver be 10, that of the barrel 1, and the number of strokes 30; then will the primitive air be found to the remaining, as 1 to $\frac{1}{10}$ nearly. — If the capacity of receiver and barrel were given, and it were required to find the number of strokes of the piston to rarefy the air to a certain degree; then from the theorem above, $e - f = gd - bd$, we get $\frac{e - f}{g - b} = d$ = the number of strokes required; which is in words, Subtract the logarithm of the remaining air from the logarithm of the primitive air; likewise the logarithm of the capacity of the receiver, from the logarithm of the sum of the capacity of the receiver and barrel together, and then dividing the first difference by the latter, the quotient will be the number of strokes required. Thus suppose the content of the receiver be equal to 600 cubic inches, and the content of the barrel be equal to 30 cubic inches, what number of strokes, or turns of the pump will rarefy the air under the receiver 800 times more than in its natural state? The answer will be, 137,007, which is the strokes and part of a turn, required to rarefy the air 800 times more than when in its natural state. If the content of the receiver be required, the other things being given, we shall find, from the above theorem, the expression will be $\frac{e - f}{d} + b = g$.

AIR-SHAFTS, among miners, are holes made from the open air to meet the adits, and supply them with fresh air.

These air-shafts, when the adits are thirty or forty fathoms in length, become absolutely necessary, in order to let in fresh air, and at the same give vent to the damps and noxious vapours.

AIR-THREADS, in natural history, a name given to the long filaments, so frequently seen in autumn floating about in the air.

These threads are the work of spiders, especially of that species called the long-legged field-spider; which, having mounted to the summit of a bush or tree, darts from its tail several of these threads, till one is produced capable of supporting the creature in the air; on this it mounts in quest of prey, and frequently rises to a very considerable height.

Nor does the spider that has thus raised itself descend always by the same thread ; it often winds that up, and darts out another, more or less long, as the creature intends a higher or lower flight.

AIR-VESSELS, in plants, are certain vessels or ducts for imbibing or conveying air to the several parts of the plant.

ARIANI, in ecclesiastical history, a branch of the Arians, who, besides the common tenets of that sect, denied the constantiability of the Holy Ghost with the Father and Son.

AIRING, in horsemanship, implies the exercising a horse in the open air ; a practice that cannot be too much commended.

AIRY, or **AERY**, among sportsmen, implies the nest of a hawk or eagle.

AIRY Triplicity, among astrologers, denotes the three signs Gemini, Libra, and Aquarius.

AISIAMENTA, in law, the same with easement. See the article **EASEMENT**.

AIVS LOCUTIUS, the name of a deity to whom the Romans erected an altar.

The words are Latin, and signify, "A speaking voice."

The following accident gave occasion to the Romans erecting an altar to the Aivus Locutius. One M. Beditius, a plebeian, acquainted the tribunes, that, in walking the streets by night, he had heard a voice over the temple of Vesta, giving the Romans notice that the Gauls were coming against them. This intimation was however neglected ; but after the truth was confirmed by the event, Camillus acknowledged this voice to be a new deity, and erected an altar to it, under the name of the Aivus Locutius.

AJUTAGE, or **ADJUTAGE**, in hydraulics, a small pipe fitted to the aperture of a jet-d'eau, or fountain. See **ADJUTAGE** and **FOUNTAIN**.

AJUTANT, in military affairs. See the article **ADJUTANT**.

AIZOON, in botany, a name given by Linnaeus to the ficoidea, and by some writers to the sedums, aloes, &c. It is also called sempervive.

ALA, or **ALÆ**, in botany, a term used in different senses ; sometimes it denotes the hollow between the stalk of a plant and its leaves ; also it is used for leaves which consist of many lobes, or wings ; sometimes it is applied to signify those petals of papilionaceous flowers between the vexillum and carina ; it is likewise used for the slender membranaceous parts of some seeds, and for those foliaceous membranes which in some plants run the whole length of the stem, whence it is called *caulis alatus*, i. e. a winged stalk, *ala* in Latin signifying a wing.

ALABASTRA, in botany, a term given to the calyx of flowers before they are expanded, particularly to the rose-bud.

ALABASTER, *Alabastrites*, in natural history,

the name of a genus of fossils, nearly allied to that of marble. It is an elegant stone of great brightness, but brittle, tho' it will receive a fine polish.

Naturalists enumerate several species of alabaster ; as, the snow-white shining alabaster, or that called the lygdine by the ancients. Boet informs us, that this stone is extremely white, and found only in Taurus ; but it was formerly brought from Arabia. It is not very compact, but heavy, and consists of a multitude of broad flat large particles, which are very bright and perfectly white. It cuts very freely, and is capable of a fine polish. There are very large strata of it in Arabia, Egypt, and many parts of Italy ; but it is seldom brought over to England.

Whitish yellow alabaster is of a soft consistence, and differs in nothing from common marble but in hardness, and in its shining when polished. It is of a loose open texture, considerably heavy, and nearly of the colour of honey, but more deep in some places than others. It consists of irregular pieces lying in tables one over another, and altogether compose a remarkable bright and very brittle mass. Besides the places above-mentioned, it has been found in Germany, France, and Derbyshire.

Yellow and reddish variegated alabaster is the common alabaster of the ancients. It is so soft that it may be cut with a knife ; and has the same name in all languages. It is remarkably bright, glittering, and almost transparent ; and its texture very loose and open, though it is moderately heavy. The ground is of a clear pale yellow, between that of honey and amber, and beautifully variegated with crooked undulated veins, some of which are broad, and others narrow ; some of a pale red, others whitish, and others again of a very agreeable pale brown. It will bear a very fine polish, and consists of large angular sparry concretions. It was formerly found only in Egypt, but is now met with in many parts of England.

A-LA-MI-RE, among musicians, is the name of a note in the modern scale of music. See **GAMUT**.

ALAMODE, in commerce, the name of a very thin, glossy, black silk, chiefly used for women's hoods and men's mourning scarfs.

ALARES Musculi, in anatomy, the Latin name of the muscles generally called pterygoidei. See the article **PTERYGOIDEUS**.

ALARM, in military affairs, implies either the apprehension of being suddenly attacked, or the notice of such an attack, signified by the firing of a cannon, musket, &c.

False alarms are frequently made use of to harass the enemy, by keeping them continually under arms.

ALARM-BELL, the bell rung upon any sudden

emergency, as a fire, mutiny, approach of an enemy, or the like.

ALARM-POST, the place appointed for drawing up a regiment in case of an alarm.

ALARM, the name of a kind of clock, contrived for waking people at a certain hour, by making an uncommon noise, &c.

ALATED Leaves, in botany, are those composed of several pinnated ones. See **PINNATED**.

ALATERNUS, in botany, the ever green privet, a plant that produces male and female flowers; the male are composed of a monophylous funnel shaped cup, cut in five segments at the brim, surrounding five small petals with the same number of filaments; the female flowers have the appearance of the male, but when examined, are without any stamina, having a trifid style placed on the germen, which afterwards becomes a round, soft berry containing three seeds.—This plant is very common in England, and vulgarly called phillyrea; the most distinguished difference between them is, that the leaves of the true phillyrea are placed opposite in pairs on the branches, whereas the leaves of the alaternus are situated alternately, whence the name is supposed to be derived.—The variegated fort, (commonly called the striped phillyrea) which is a beautiful plant, is increased by layers, and the other species by layers or seeds; this genus of plants are classed by Linnaeus with the rhamnus. See the article **RHAMNUS**.

ALBANENSES, the name of certain heretics, who troubled the peace of the church in the seventh century. They revived in a great measure the errors of the Manicheans, and other sectaries, which had been dropt for near three hundred years. Their first reverie consisted in establishing two principles, the one good and the other evil; to the latter they attributed all the books of the Old Testament, which they rejected with abhorrence; the former they said was the father of Jesus Christ, the fountain of good, and author of the New Testament. They affirmed that the world had existed from eternity; denied any resurrection of the body; and held with Pythagoras, the transmigration of souls. They asserted, that a man has a power of giving himself the holy spirit; and that the accounts we read of hell are all fable and fiction; with other tenets equally unchristian, wild, and ridiculous.

ALBANI, in antiquity, a college of the Salii, or the priests of Mars, so called from Mount Albanus, the place of their residence.

ALBATI, a sort of Christian hermits, who flourished in the year 1399, during the pontificate of Boniface IX. They were so called from the white linen which they wore. They came down from the Alps into several provinces of Italy, under the conduct of a priest clothed in white, and holding a crucifix in his hand. The follow-

ers of this priest, whose great zeal made him looked upon as a saint, multiplied so fast, that it alarmed the pope, who, sending foldiers, apprehended and put him to death; upon which his followers immediately dispersed. These monks professed sorrow and weeping for the sins and calamities of the times: they eat together in the highways, and slept promiscuously.

ALBE, a small piece of money, current in Germany, worth about three halfpence.

ALBERTUS, a gold coin, worth about fourteen shillings; it was coined during the administration of Albertus, archduke of Austria.

ALBIGENSES, a sect of heretics who sprung up in the twelfth century: they were so called from one Oliver, a disciple of Peter de Valdo, or Waldius, who first spread his errors at Albi, a city of Languedoc, on the banks of the Tarn.

If we believe the catholic writers, this sect was the very hodge-podge, or scum of all the heretics, that have started up since the first propagation of christianity. It contained the essence of all the errors which had been advanced by the Basilidians, Arians, Manicheans, &c. mixed up with a thousand absurd ingredients of their own invention. Yet bad as it was, it gained so considerable a ground against the corruptions of the Romish church, and the profligacy of their clergy, that it was not suppressed without great bloodshed and murders. They were at first supported by Raymond, count of Toulouse, when the catholics agreed upon a holy league, or crusade against them. He was joined by the king of Arragon, but was defeated at the siege of Muret, where he was killed, and the defeat followed by the surrender of the city of Toulouse, and the conquest of the greatest part of Languedoc and Provence. His successor agreed with the pope to set up the inquisition in his state, and to extirpate the Albigenes. In an assembly held at Milan, the archbishop of Toulouse drew up articles, agreeable to which the count made a most ample declaration against them, which he published at Toulouse in 1253. This completed the ruin of the Albigenes.

ALBITROSSE, the name of a bird, very common in several parts of the West-Indies; but not reduced to any certain genus.

ALBORAK, among Mahometan writers, the beast on which Mahomet rode in his journey to heaven.

ALBUGINEA Tunica, in anatomy, the third or innermost coat of the testicles, so called from its white colour.

ALBUGINEA is also a name given by some anatomists to one of the coats of the eye, called also adnata. See the article **EYE**.

ALBUGO, among physicians, denotes a distemper of the eye, caused by a white, dense, and opaque spot, growing on the tunica cornea.

The

The word is formed from the Latin *albus*, white.

This is a troublesome disease, which is more or less offensive to the sight, according to the greater or less portion of the transparent part of the cornea affected by it: for sometimes it fixes on the exterior surface only of this membrane, sometimes on the interior, and sometimes it runs more or less deep into it.

It is most commonly the consequence of inflammations, by the extravasation of humours between the membranes of this tunicle, and particularly in the small-pox, by the suppuration of pustules upon this part.

I have, says the learned Dr. Mead, made use of two methods of cure for this disorder of the sight; the one in the outward fort, the other in the inward. In the former case I ordered the following powder:

Take of common glass any quantity; pound it in a mortar, into a very fine powder; then add an equal quantity of white sugar-candy, and levigate the mixture on a marble with great labour, till it becomes quite impalpable.

A little of this powder, put into the eye with a quill every day, gradually absterges and wears off the spot by its inciding quality. The other method above-mentioned of removing this speck is, to order a dexterous surgeon to pare it cautiously every day with a knife; for this tunicle is composed of several lamellæ one over another, and has thickness enough to bear paring off some of its parts. I have seen several instances of cures by the eye-powder, but the paring of the coat has not succeeded with me above once or twice. However, it is better to try a doubtful remedy than none. *Mead's Monita & Præcepta.*

ALBUM *Græcum*, in the old materia medica, the white dung of dogs, said to be good for inflammations of the throat; but it is little regarded at present.

ALBUMEN, a term used by medical writers for the white of an egg.

It is used in collyriums, on account of its cooling and agglutinating quality: it is also often an ingredient in ointments for burns.

ALBURN, the English name for a sort of compound colour, formed by mixing red and white.

ALCAICS, a name given to several different kinds of metre, which were made use of by the Greeks and Latins: they are so called from the inventor of them Alcæus, a famous Lyric poet, born at Mitylene, in the island of Lesbos, about the 44th Olympiad. He was coteremporary with the celebrated Sappho; and left several works behind him, of which only a few fragments are now remaining. He was an inveterate enemy to tyrants, and particularly to Pittacus and Periander; for

which reason, Horace mentions him thus:

— *Alcæi minaces*

Stesichorique graves cœmœne.

The first species of Alcaic verse is of four feet, and consists of a spondee or trochee, a bacchius, and two dactyles, as thus:

Jūstūm ēt | tēnācē | prōpōsī | tī vīrūm.

In every stanza, where this kind of metre is used, the two first verses are of this sort; the other two verses differ, the third being an iambic dimeter hypercatalectic, i. e. with a long syllable over and above, as

Nōn vūl | tūs īn | stāntīs | tyrān | nī.

And the fourth verse an alcaic, which consists of two dactyles and two trochees, or a trochee and a spondee, as,

Mentē quā | tū sōlid | ā, nec | Aūster.

The following is a complete alcaic stanza,

Vēstīr | cœmœnæ, | Vēstīr īn | ārdūos.

Tōllīr | Sābīnōs; | sēu mībī | frīgīdum.

Præfēs | tē, sēu | Tībīr | sūpī | num,

Sēu līquī | dāe plācū | erē Bāiæ!

Besides these two sorts of alcaic verse, which are called dactylic, there is another called simply alcaic, which consists of an epitritus secundus, two choriambuses, and a bacchius; as thus,

Fīlīūm dī | cīnt Thētīdīs | sub lācrīmō | sū Trōjāē.

ALCAIC Ode, a kind of manly ode, composed of several strophes, each consisting of four verses; the two first of which are always alcaics of the first kind; the third verse is a dimeter hypercatalectic, or consisting of four feet and a long syllable; and the fourth verse is an alcaic of the second kind. The following strophe is of this species, which Horace calls *minaces Alcæi cœmœne*.

Non possidentem multa vocaveris

Reclite beatum: rectius occupat

Nomen beati, qui deorum

Muneribus sapienter uti, &c. Hor.

ALCAID, ALCAÏDE, or ALCALDE, among the Spaniards and Portuguese, is a magistrate, or officer of justice, answering nearly to our justice of peace. The alcaid is properly a Moorish officer, where he is invested with supreme jurisdiction, both in civil and criminal cases.

ALCALI, or ALKALI, a general appellation given by physicians and chemists to all substances, which, on being mixed with acids, excite an effervescence.

The word originally signified the salt extracted from the ashes of *kali*, or glasswort: but was afterwards applied to all salts that effervesced with acids.

Alcalies are generally divided into two kinds, and distinguished by the epithets of *fixed* and *volatile*.

Fixed ALKALIES are distinguished from saline substances not alkaline, by their effervescing with all acids, forming with them neutral salts, precipitating

pitating' solutions made in acids, and changing syrup of violets green.

They are distinguished from volatile alcalics by their fixity and fusibility in the fire, by their deliquiating in the air, and never assuming a crystalline form, changing solution of mercury sublimate not white, but of an orange yellow, producing no blue colour with copper or its solutions, raising no visible cloud when placed near an unstopt bottle of nitre, occasioning no coldness but rather heat on being dissolved in water. Pure fixed alcalies, dissolved in water, mingle with a solution of any other pure alkali, without the least precipitation, turbidness, or sensible change.

They form, with acids, different neutral salts, according to the nature of the acid employed; with the vitriolic, a bitterish salt, very difficult of solution in water, and not fusible in the fire, commonly called vitriolated tartar, the alkaline salt made from tartar being that which has chiefly been employed for these purposes; with the nitrous acid, they form a perfect nitre; with the marine, a salt greatly resembling sea-salt, being in some respects different from the common vegetable alkalies. They readily crystallize with any of the mineral acids, and with tartar; with which last they compose a neutral salt, much easier of solution than the tartar itself, and hence called soluble tartar. They do not easily crystallize with the acid of vinegar or lemon juice; these mixtures, if by careful management reduced to a crystalline form, soon deliquesce again in the air.

Preparation of fixed ALCALIES. The most commodious method of preparing fixed alkaline salts in the large way, seems to be that directed by Kunckel in his Art of Glass. The ashes of wood, or the woody part of vegetables, either burnt on purpose or as common fuel, are to be put into a large tub or vat, whose bottom is covered with pieces of split wood and straw, to prevent the ashes from stopping up the cock. So much water is to be poured on the ashes as may totally cover them: after standing for a night, the liquor, impregnated with their saline part, is to be let off by the cock at the bottom into another vessel; and the elixation repeated with fresh water so long as the ley has any saline taste. The elixated ashes may be used, like common wood-ashes, for manure; and the weak leys may be rendered stronger, by pouring them, instead of plain water, upon a fresh quantity of ashes. Thus from every parcel of ashes we obtain a strong ley, with a weaker one to be returned on the next. Where the ley is to be kept in its liquid state, wooden vessels (according to him) are more commodious than earthen ones, however glazed; these last being sooner corroded and penetrated by the acrid liquor.

In procuring a solid salt, the ley is to be evaporated in an iron pan, fixed in brick-work; fresh

ley being continually supplied during the evaporation, in a very slender stream, from a cask placed on the brick-work, till the quantity of salt is as large as can be conveniently dried in the vessel. This impure brown or blackish salt is to be calcined in a furnace built for that use, with a red heat just not strong enough to melt it, and every now and then turned up and stirred for six or seven hours, or till some of the larger pieces, taken out and broke, appear internally white. Thus we obtain an alkali sufficiently pure for all the businesses in which these kinds of salts are employed: if, for particular purposes, a further purification should be required, it may be dissolved, inspissated, and calcined afresh. The rough salt loses, in the first calcination, commonly about one tenth of its weight.

Some soak in the ley a quantity of straw, bean-stalks, or other like substances, sufficient to imbibe it; and, by drying and burning these, obtain the salt of the ley, without the trouble of boiling it down. The earthy matter left by the straw is, in quantity, inconsiderable, and, for many purposes, of no injury to the salt, particularly for soap-boiling, bleaching, &c. where the salt is dissolved, and consequently purified from indissoluble earthy admixtures before it is used. There is nevertheless one great inconvenience in the process; the straw, when loaded with the alkali, being very difficultly made to burn. Vegetable substances in general, when fully impregnated with fixed alkaline salts, never flame; and do not burn at all without a continuance of external heat, inasmuch that some have proposed the impregnating of wood for buildings; with salts, as an effectual means for preventing its receiving or communicating fire.

The strength of leys, or the quantity of salt dissolved in them, may be estimated by the weight of a certain measure of them, compared to the weight of an equal measure of water; or more commodiously, and perhaps as accurately, by means of an hydrometer graduated from actual trials with leys of known strength. *Neumann's Chemistry.*

Volatile ALCALIES, are salts formed by a new combination of the constituting particles of a natural body, by the operation of putrefaction.

Volatile alkalies from whatever substance obtained, are all alike, and have the same properties; differing only according to their degrees of purity. The volatile alkali, as well as the fixed, consists of a certain quantity of acid, combined with and entangled by a portion of the earth of the mixed body from which it was obtained; and on that account it has many properties like those of a fixed alkali. But there is, moreover, in its composition, a considerable quantity of a fat or oily matter, of which there is none in a fixed alkali;

alkali; and, by this means, there is a great difference between them. Thus the volatility of the alkali produced by putrefaction, which is the principal difference between it and the other kind of alkali, whose nature it is to be fixed, must be attributed to the portion of oil which it contains: for there is a certain method of volatilizing fixed alkalies, by means of a fatty substance.

Volatile alkalies have a great affinity with acids, unite therewith rapidly and with ebullition, and form with them neutral salts, which shoot into crystals, but differ from one another according to the kind of acid employed in the combination.

The neutral salts which have a volatile alkali for their basis are in general called ammoniacal salts. That whose acid is the acid of sea-salt, is called sal ammoniac. As this was the first known, it gave name to all the rest. Great quantities of this salt are made in Egypt, and thence brought to us. They sublime it from the foot of cows-dung, which is the fewel of that country, and contains sea-salt, together with a volatile alkali, or at least the materials proper for forming it; and consequently all the ingredients that enter into the composition of sal ammoniac. See the Memoirs of the Academy of Sciences.

The neutral salts formed by combining the acids of nitre and of vitriol with a volatile alkali, are called after their acids, nitrous sal ammoniac and vitriolic sal ammoniac: the latter, from the name of its inventor, is called Glauber's secret sal ammoniac.

ALCANNA, in commerce, a powder prepared from the leaves of the Egyptian privet, in which the people of Cairo drive a considerable trade. It gives a yellow colour, when steeped in common water; and a red one when infused in vinegar or alum water. They also extract an oil of a very agreeable odour from the berries of the alcanna, and use it in medicine.

Knights of ALCANTARA, a military order in Spain. The knights of this order make a very considerable figure in the history of the Spanish expeditions against the Moors.

ALCE, in natural history, the name of an animal, generally called the elk. See the article ELK.

ALCEA, the hollyhock in botany, a biennial plant of the mallow kind; it grows to the height of eight or nine feet, ornamented with large rosaceous flowers, which are pentapetalous: those that are most esteemed produce double flowers of various colours, which make a magnificent appearance in July and August, the seeds of which should be sown in the spring, and in the succeeding autumn planted where they are designed to remain for flowering. The vervain mallow, called also

alcea, is not of this genus, but a species of the mallow. See the article MALLOW.

ALCHEMILLA, ladies mantle, in botany, a genus of tetandrious plants; the common sort, which grows in several parts of England, has roots that are composed of many thick fibres, which greatly spread in a proper soil; the leaves supported by long foot stalks, are roundish and scolloped about their extremities, arising immediately from the root, from between which the flower stems shoot forth about a foot high, divided into many branches; the cup of the flower is monophyllous and herbaceous, cut into eight segments: it is destitute of petals, but in the center of the empalement is situated an oval germen, into which is inserted a long style, crowned with a globular stigma, surrounded by four upright filaments, resting on the edge of the empalement, and topped with roundish summits: when the flower is decayed, the germen becomes a single compressed seed. This plant is recommended by some as an excellent vulnerary, and is said to consolidate, astringe, and thicken the blood, which makes it be prescribed in hæmorrhages and other fluxes.

ALCHEMIST, a person who professes, or practises the art of alchemy.

ALCHEMY, the sublimer, or more abstruse parts of chemistry. See the article CHEMISTRY.

The word is formed from the Arabic particle *al*, which signifies sublime, or excellent, and *chemy*, chemistry. The term therefore properly signifies the *sublime chemistry*, or the *chemistry*, by way of excellence.

ALCIS, in mythology, the name under which Minerva was worshipped by the Macedonians.

ALCMANIAN, in ancient lyric poetry, a species of verse consisting of two dactyls and two trochees. The following is of this kind:

Virgini | bus pue | risque | canto.

ALCOHOL, in chemistry, signifies spirit of wine rectified by repeated distillations, till it has acquired the utmost subtilty and perfection possible.

By these repeated rectifications, it is not only freed from its redundant phlegm, but also from some particles of acid and oil, which, though much less volatile than itself, ascend with it in the first distillation; nor is it possible wholly to avoid this inconvenience. See SPIRIT.

ALCOHOL also signifies a very fine impalpable powder. The oriental ladies use antimony, reduced to an impalpable powder, for blacking their eye-lids, and call this powder alcohol.

ALCOLA, a term used by some alchemists for the tartar of urine, found in small grains of a reddish colour.

ALCOR, in astronomy, the Arabic name of a star of the 5th magnitude, adjoining to the large

bright star in the middle of the tail of the great bear, or *ursa major*. We are told in Wolfe's *Lex Math.* page 34, that it is a proverb among the Arabians, "That thou can see alcor, and yet not see the full moon;" which they apply to such persons, who are apt to see small things, and overlook much greater.

ALCORON, AL-CORAN, or AL-KORAN, the scripture, or bible of the Mahometans.

The word is compounded of the Arabic particle *al*, and *coran*, or *koran*, derived from the verb *caraa*, or *karaa*, to read; the true sense therefore of the word is, *the reading*, or that which ought to be read.

The alcoran is divided into 114 large portions, of very unequal length, which we call chapters, but the Arabians *sawar*, which properly signifies a row, or series. These chapters, in the manuscript copies, are not distinguished by their numerical order, but by particular titles, which are sometimes taken from some principal matter treated of, but generally from the first word of note that occurs.

Every chapter is subdivided into smaller portions, which we usually call verses, but the Arabians, *aiat*, which signifies signs or wonders; such are the secrets of God, his attributes, works, &c. delivered in those verses.

The alcoran is universally allowed to be written in the purest language, and to be the standard of the Arabic tongue. The style is, in general, beautiful and fluent, especially where it imitates the prophetic manner, and Scripture phrases. It is concise, and often obscure, adorned with bold figures after the eastern manner, enlivened with florid and sententious expressions, and in many places, especially where the majesty and attributes of God are described, sublime and magnificent.

The general design of the alcoran was, to unite the professors of the three different religions then followed in the populous country of Arabia, who, for the most part, lived promiscuously, and wandered without guides, the far greater number being Pagans, and the rest Jews and Christians. In order to perform this, Mahomet pretended to be the ambassador of God, who, after the repeated admonitions, promises, and threatenings of former ages, had sent him to establish the true religion upon earth by force of arms, and appointed him chief pontiff in spiritual, and supreme prince in temporal affairs.

The great doctrine of the alcoran is the unity of God; and to restore that fundamental principle of true religion, Mahomet pretended was the chief end of his mission. But there are many occasional passages in it, relating to particular emergencies; for whenever any thing happened to perplex the false prophet, he always had recourse to a new

revelation: and hence there are several passages in the alcoran contradictory to one another. The Mahometan doctors, however, obviate any objection that might be raised on this subject, by saying, that God commanded several things in the alcoran, which for good reasons were afterwards revoked and abrogated.

That Mahomet was really the chief contriver of the alcoran is beyond dispute; though it is highly probable, that he had no small assistance in his design from others; particularly from one Sergius, a Nestorian monk, and a Jew named Abdallah Ebn Salam. The Mahomedans however absolutely deny that the alcoran was composed either by their prophet himself, or any other person; it being their general and orthodox belief, that it is not only of divine original, but even eternal and uncreated, remaining, as some of them express it, in the very essence of God; that the first transcript has been from everlasting by God's throne, written on a table of vast bigness; that a copy from this table, in one volume on paper, was, by the ministry of the angel Gabriel, sent down to the lowest heaven in the month of Ramadan, whence Gabriel revealed it by parcels, some at Mecca, and some at Medina, at different times during the space of twenty years, as the exigency of affairs required; giving Mahomet, however, the satisfaction of seeing the whole once a year. They add, that this original copy was bound in silk, and adorned with gold and precious stones of paradise.

Hence it is easy to conceive, that this book is held in the highest esteem and reverence among the Mahometans. They dare not so much as touch it without being legally purified. They read it with great attention and respect, never holding it below their girdles. They swear by it, consult it on the most weighty occasions, carry it with them to war, write sentences of it in their banners, adorn it with gold and precious stones, and, knowingly, do not suffer it to be in the possession of any of a different persuasion.

ALCOVE, among builders, signifies a recess, or part of a chamber, separated by an estrade, or partition of columns, and other corresponding ornaments, in which either a bed of state is placed, or seats to entertain company.

ALDEBARAN, in astronomy, a star of the first magnitude in the eye of Taurus, and in England is commonly called the bull's-eye; it is marked α by Bayer, and is the 87th in Mr. Flamsteed's catalogue. The place of this star has been settled with great accuracy at the Royal Observatory at Greenwich, in the late Dr. Bradley's time, from observations of the sun near the time of his passing the equinox. See the constellation or sign Taurus, for his right Ascension, Declination, Variation,

tion; &c. which has been determined from the mean of 2000 observations, and may be looked upon as one certain given point in the heavens, whereby astronomers may settle the theory of the planets, as well as navigators determine their longitude at sea, by observing his distance from the Moon. See **LONGITUDE**.

ALDER, *Alnus*, in botany, a genus of trees that produces male and female flowers; the male are digested into a long cylindrical loose catkin, and each contain four small stamina; the female flowers, which are connected into a scaly head, are without petals, but have each an oval germen, on which are affixed two styles, extended the length of the scales, crowned with a single stigma: when the flower is decayed, the germen becomes an oval seed inclosed in the scale of the fruit. The sort which is most common delights to grow in watery places, where few other trees will thrive; they are propagated by layers, or from branches cut about three feet long, and planted in February or March: this plant may also be raised from seeds. The alder is reckoned very proper to make hedges in moist places, and the wood is of great use to turners, &c. The different species of the alder are classed by Linnaeus with the betula or birch. See the article **BIRCH**.

ALDER bearing black berries. See **TRANGULA**.

ALDERMAN, the second degree of nobility among the Anglo-Saxons, and now the second degree in cities or corporations; the mayor being the head, the alderman the next, and the common-council the third, or lowest degree.

The word is derived from the Saxon earldeorman; that is, a senior, or alderman, which, by degrees, came to stand for persons of the greatest distinction, because such were chosen to discharge the highest offices, being those whose long experience rendered them most capable, and whose birth and fortune made them most conspicuous; and as they were generally intrusted with the government of the counties, instead of saying the governor, it was said the earldeorman of such a county; and by degrees this word came to signify the governor of a county, or city. While the heptarchy lasted, these officers were only during the king's pleasure; at last they were for life, at least for the most part. After the Danes were settled in England, the title of earldeorman was changed into that of earl, and the Normans introduced that of count, which, though different in its original signification, meant however the same dignity.

At this time aldermen are associates to the mayor, or civil magistrates of most of our municipal or corporate cities or towns, who form a kind of council, and regulate matters according to the policy of the place: sometimes they also take cognizance of civil and criminal matters, but very rarely, and in particular cases: their number is not

limited, being in some places six, and others twenty-six, out of which are annually chosen the mayors, or chief magistrates, who, at the expiration of their mayoralty, devolve again into aldermen.

An alderman ought to be an inhabitant of the place, and resident where he is chose; and if he removes, he is incapable of doing his duty in the government of the place, for which he may be disfranchised.

ALE, a fermented liquor obtained from an infusion of malt, and differing only from beer in having a less proportion of hops.

There are various sorts of ale known in England, particularly pale and brown; the former is brewed from malt slightly dried, and is esteemed more viscid than the latter, which is made from malt more highly dried or roasted.

Medicated ALES, those wherein medicinal herbs have been infused, or added during the fermentation.

Gill ALE is that in which the dried leaves of gill or ground-ivy have been infused. It is esteemed absterfve and vulnerary, and consequently good in disorders of the breast and obstructions of the viscera.

ALE-CONNER, an officer in London, who inspects the measures used in public houses.

There are four ale-conners, who are all chosen by the common-council of the city.

ALE-SILVER, a tax paid annually to the Lord-mayor of London, by all who sell ale within the city.

ALEA, a surname given to Minerva by Aleus, king of Arcadia, who built a temple to that goddess in the city of Tegea, the capital of his kingdom. In that temple were preserved the hide and tusks of the wild boar Calydon.

ALECTO, one of the three furies of hell, the daughter of Acheron and Night. See **FURIES**.

The word is Greek, and signifies *envy*.

ALECTORIA, in natural history, a stone said to be formed in the stomach, liver, or rather gall-bladder of old cocks; and to which the antients attributed many fabulous virtues.

The word is Greek, and derived from αλεχτρον, a cock.

ALECTROMANCIA, in antiquity, a species of divination performed by means of a cock, in the following manner: a circle being described on the ground, and divided into twenty-four equal portions, in each of which was written one of the letters of the alphabet, and a grain of wheat placed on each of the letters; this being finished, a cock was turned loose in the circle, and particular notice taken of the grains picked up by the bird; because the letters under them being formed into a word, gave an answer to the question.

The word is Greek, and compounded of αλεχτρον, a cock, and μαντεια, divination.

A-LEE, in navigation, when a ship leans over to one side more than the other, by the wind thwarting the line of her course, and pressing upon her masts and sails, which act upon her hull with the power of a lever, the side pressed down is called the lee-side; hence when the helm is moved close to it, it is said to be a-lee, or hard a-lee: the other side is then called the weather-side, and the helm being moved over to it, is said to be hard a-weather.

ALEGAR, a kind of vinegar made of ale.

ALEMBIC, a chemical vessel usually made of glass, or copper, for condensing the vapours that rise in distillation; for the alembic is properly the head or upper part of the apparatus used in distilling; though it is often used to signify the whole. See the articles STILL, and DISTILLATION.

ALEPH, the name of the first letter in the Hebrew alphabet, from which the *alpha* of the Syrians and Greeks was formed.

The word properly signifies chief, prince, or thousand. There are some of the Psalms and other parts of scripture which begin with Aleph, and the other verses of them are continued with the other letters of the alphabet. The modern Jews use their letters as cyphers. Aleph stands for one; Beth for two; Gimel for three, &c.

ALESANDERS, or ALEXANDERS, in botany, the English name of a plant that produces umbelliferous pentandrious flowers, with leaves resembling smallage. It was formerly used in cookery, with the same intention as celery; it is reckoned a balsamic, but at present is little used either in the shops or kitchen. There are different species of this plant, all classed by botanists under the general name SMYRNIUM.

ALEXANDRINE, the name of a kind of verse, which consists of twelve syllables. It was so called from a poem written in French, in this metre, stiled the Alexandriad. It was frequently made use of by our old poets, even in whole poems: Spenser constantly ends every stanza of his *Fairy Queen* with one of these verses. Dryden was of opinion, that it might be introduced with great propriety, at the close of a sentence, to give an air of solemnity and majesty to the thought; and accordingly we frequently meet with it in his works. It is now very much disused, which might be owing, in some measure, to the following censure passed upon it by Pope, in his *Essay on Criticism*:

Then, at the last, and only couplet, fraught
With some unmeaning thing they call a thought,
A needless *Alexandrine* ends the song,
That, like a wounded snake, drags its slow
length along.

Our Alexandrine verse answers exactly to the

Trimeter Iambic of the ancients, as may be seen from the two following lines,

Quid is tē fert | tumultus? cū | quid omnium. Hor.
And all the day | in doing good, | and godly deeds.
Spens.

ALEXIPHARMICS, in medicine, are properly remedies for expelling or preventing the ill effects of poison: but some of the moderns having imagined that the animal spirits, in acute distempers, were affected by a malignant poison, the term has been understood to mean medicines adapted to expel this poison by the cutaneous pores, in the form of sweat. In this sense, alexipharmics are the same as sudorifics.

The word is formed from the Greek, *αλεξω*, to expel, and *φάρμακον*, a poison.

ALEXITERIAL, among physicians, a term of much the same import with alexipharmic; though sometimes used in a synonymous sense with amulet.

ALFAQUES, among the Moors, the name generally used for their clergy, or those who teach the Mahometan religion, in opposition to the Morabites, who answer to the Monks among the Christians.

ALFET, in our old customs, denotes a cauldron full of boiling water, wherein an accused person, by way of trial or purgation, plunged his arm up to the elbow.

ALGA, in botany, a genus of submarine plants, called in English glass-wreck, composed of long slender leaves of a dusky-green colour, very much resembling some kinds of grass.

Authors enumerate several species of alga, the most considerable of which is the *alga-marina*, the salt of which is so much used in the glass trade.

ALGAROT, or ALGARET, in chemistry, an emetic powder prepared from regulus of antimony.

ALGEBRA, an universal arithmetic, or general method of computation by certain signs, symbols, or characters; or the method of solving problems and raising theorems by means of equations.

The word *algebra* is certainly derived from the *Arabic*, but there have been some mistakes as to its meaning. When it was first introduced in Europe, it was understood to be the invention of the famous philosopher Geber; and by some authors is sometimes called *regula algebrae*, and sometimes *regula Gebro*, which signifies nothing more than Geber's rule. But since the Arabic language has become more familiar in those parts, it is well known that the Arabians called this art *al-gjabr w'al-makabala*, which is literally the art of resolution and equation; from hence we may infer, that the true derivation of the word *algebra*, is from the Arabic name of the art; and not from the supposed inventor

inventor Geber. Whether the Oriental philosophers or the Greeks were the first inventors of algebra, is yet disputed; but it is very certain, that it was handed to us by the Moors, who had it from the Arabians; but whether they are indebted to the Persians and Indians, or to the Greeks, is yet a dispute. However, it must be allowed that the algebra taught us by the Arabians differs very much from that contained in the works of Diophantus, the oldest Greek author on this art which is now extant. But all these difficulties, which have given great men so much trouble, may be easily surmounted, if we suppose that the invention was originally taken from the Greeks, and new-modelled by the Arabians in the same manner as we know common arithmetic was: for this, which is extremely probable, makes the whole plain and clear, and leaves us the liberty to pursue the progress of this art; which, when it became better known to the Europeans, received different names. The Italians styled it *ars magna*, which in their own language is *Parte maggiore*, opposing to it common arithmetic as the common or lesser art. It was also called *Regula Cosæ*, the Rule of Cos; because the Italians make use of the word *Cosa*, to signify what we call root, and from thence this kind of learning being derived from them to us, the root, the square, and the cube, were called Cosmic numbers, and this science the Rule of Cos.

Lucas de Burgo Sancti Sepulchri published at Venice, under the title of, *A compleat treatise of arithmetic and geometry, proportions and equations*, the first book which is now extant on this subject. It was printed so early as 1494, and is a very correct treatise: he ascribes the invention of algebra to the Arabians, uses their method, and treats very clearly of quadratic equations.

After him several authors in Germany and Italy wrote on the same subject; but still the art advanced very little, till the famous Jerom Cardan printed at Nuremberg, in 1545, in folio, a treatise with this title, *Artis magna sive de regulis algebraicis, liber unus*; and soon after a smaller piece, with the title of *Sermo de plus & minus*, wherein were rules contained for resolving cubic equations, which have since been called Cardan's rules, tho' they were not invented by him, but as himself owns, by Scipio Ferreus of Bononia and Tartagila. The next celebrated writer was a French monk, whose name was Boteon, better known to the learned by the Latin appellation of Buteo. He published in 1559, his *Logistica*, in which there was a treatise of algebra, which gained him great reputation: yet his excellency lay in a clear and copious manner of writing; nor does it appear that he added any thing to what had already been discovered, except some corrections as to Tartagila's method of managing cubic equations. Hitherto nothing was known of the Greek Analy-

sis; but in 1575, Xilander published Diophantus, or at least a part of his works, which are still remaining, and this quickly changed the face of things; for it presently appeared, that his was a neater and more easy method, and withal opened a path to much greater discoveries, which was the reason that the succeeding algebraists quitted the terms made use of by Arabic writers, and adopted his. The time which Diophantus flourished is not thoroughly settled. Vossius thinks he lived in the second century, but others place him in the fourth; his works were known to the Arabians, and translated by them; nay it is said, they have still those seven books of arithmetic of his which are lost to us. The famous Arabian historian Abul-Pharajus, whose works were published by the learned Pocock, not only mentions him, but ascribes to him the invention of algebra; but in this he is to be understood as writing according to the lights he had; for though it be true that Diophantus Alexandrinus is the oldest author we have which treats expressly of the analytic art, yet the footsteps thereof are visible in much older writers. Theo, who is thought to have explained the five first propositions in the thirteenth book of Euclid in the analytic way, gives the honour of the invention to Plato, and indeed it seems very agreeable to his genius and method of reasoning on mathematical subjects. By the junction of both lights, and a proper connection of the Arabic method of investigation with the Greek terms, which were much shorter and easier, algebra quickly became a much more useful as well as considerable science than it was before.—In our own country, the first writer on algebra that was known of, was Dr. Robert Record, a physician, who distinguished himself in the reign of queen Mary, by his skill in the mathematics. He first published a book of arithmetic, which continued the standard for that branch of learning for many years; and in 1557 he sent abroad a second part, under the title of *Cos ingenii*, or the *Whetstone of wit*, which is a treatise of algebra; the word *Cos* alluding to Cosmic numbers, or the Rule of Cos, by which name, as has been before shewn, this art was known. This treatise is really a great curiosity, considering the time in which it was published, and, together with his other works, must give us a high idea of the man's industry and application.

But notwithstanding the early publication of this piece, and that some English gentlemen in their travels acquired some knowledge of this kind, as appears by a Spanish treatise of algebra, published by Pedro Nunnez, in 1567, yet it continued to be so little cultivated in England, that John Dee, in his mathematical preface, prefixed to Sir Henry Billingsley's translation of Euclid, printed at London in 1570, speaks of it in very high terms, and as a mystery scarce heard of by the studious in the

mathematics here: however, it is plain from some of his annotations on Euclid, that he was tolerably versed therein, and was even acquainted with the manner of applying it to geometry. In 1579, Leonard Digges, a great mathematician for those times, printed a treatise of algebra in his *Stratagemas*, after which it came to be better known, and more studied, to which contributed not a little the improvements made by the author we shall next mention.

Franciscus Vieta, who for his attachment to the mathematics, and especially this part of it, is well known.

About the year 1590, he published a treatise of algebra in quite a new method; and by a judicious mixture of the Greek and Arabian rules, with some improvements of his own, introduced the mode of calculation which is still in use under the title of *Specious Arithmetic*. Before this time, only unknown quantities were marked by letters, but such as were known were set down in figures, according to the usual notation. He made use of letters for both, only with this distinction, that the known quantities he represented by consonants, and the unknown by vowels.—By this contrivance he greatly extended the science, and, which was more, shewed its capacity of being farther extended: for, whereas former algebraists had confined their investigations to the particular questions proposed to them, he by this means produced theorems capable of resolving all demands of a like nature, instead of particular solutions.—The learned Dr. Wallis has accounted very clearly for the new title that Vieta gave to his algebra.

The Romans had a method of stating law questions under general names, such as Titius and Sempionius, Caius and Mævius, whence we derive our way of using ABCD on such occasions, which methods of stating the civilians stile *species*, in opposition to the stating of real cases by true names.

Vieta having made a change of the same nature in algebra, and being a lawyer by profession, he borrowed from that science the title of his new invention, which was received with universal applause: we have likewise many of his works under the name of Apollonius Gallus, which he assumed on account of his first attempting to restore the works of Apollonius Pergæus.—About the same time flourished Raphael Bombelli, an Italian, who published at Florence a treatise of algebra, wherein he first taught how to reduce a bi-quadratic equation to two quadratics, by the help of a cubic.—Our own countryman, Mr. William Oughtred, was the next great improver of algebra. Building however on what Vieta had already performed, he introduced such a conciseness, and withal so plain and perspicuous a method of inves-

tigating geometrical problems, as acquired him immortal reputation. His *Clavis Mathematicæ*, or Key of the Mathematics, was first published in 1631, and is perhaps the clearest, and most compendious system hitherto extant.

In this work he contented himself with the solution of quadratic equations, reserving those of a higher power for another work, which was the *Exegetis Numerosa*, which in later editions is joined to his *Clavis*.

In both pieces there were abundance of additions and improvements, and the doctrine of proportions more fully and clearly stated than it hitherto had been; but the greatest excellency of Mr. Oughtred's book was the application of the analytic method to geometry, which he did in a variety of cases, and enabled his disciples to proceed still farther than he had done.—Contemporary with him was Mr. Thomas Harriot, an excellent mathematician, and who made still greater improvements in this science. He is placed after Oughtred, though he died long before him, because his book was not published till some time after the first edition of Oughtred's *Clavis*. It was then printed in a thin folio, by the care of Mr. Walter Warner, under the title of, *Artis analyticae praxis ad æquationes algebraicas, nova, expedita & generali methodo, resolvendas, tractatus posthumus, &c.* that is, A treatise of the analytic art, containing a new, expeditious, and general method of resolving equations; a posthumous tract, by the late learned Mr. Thomas Harriot. The publisher Mr. Warner prefixed a preface of his own, containing a very judicious, though concise, representation of the several parts of algebra, their nature and dependence on each other, the extent and usefulness of this art, and the progress thereof to this time. In Mr. Harriot's book, algebra takes a new form, and from him alone it met with more improvements than it had done from all who had studied, or at least all who had written upon it before him.—It is divided into two parts, and the author begins his improvement by removing every thing that was useless, superfluous, or inelegant in other methods: thus, instead of capitals, he introduced small letters; instead of the terms squares, cubes, sursolidis, &c. and their contractions, he brought in the powers themselves, which made the operations much more easy, natural, and perspicuous, than they were before. Having thus established a plain and accurate notation, he proceeds to a multitude of new discoveries, of which, to the number of twenty-three, the reader may find a full, distinct, and very judicious account, in the celebrated treatise of Dr. Wallis.

From this admirable piece of Mr. Harriot's, Des Cartes took all the improvements he pretended to make, as the Doctor justly observes, and of which

which we shall furnish the reader with some concise, and we think conclusive proofs. First, It appears from the accounts we have of the life of Des Cartes, that he was here in England when Harriot's book was published, which being written in Latin, in a branch of learning about which that great man was then very sedulous, it is easy to conceive that he was one of his first perusers: Secondly, It is certain that he did not publish any thing on the subject before that year: Thirdly, His treatise of geometry, wherein these new improvements first appeared, was printed in French in 1637, without his name; which, in all probability, was to try what opinion the world would have of them, and whether any one of the French mathematicians could discern whence they were taken: Fourthly, Though he suffered the two first parts of his book to be published in Latin, with his name, in 1644; yet the third part relating to geometry, did not appear till 1649, when it was published by Francis Van Schooten. These are probable reasons only: but then, Fifthly, He follows Harriot distinctly in nineteen several discoveries; which, that they should be made in the same method and manner, (except a few mistakes) without consulting Mr. Harriot, is altogether incredible, and was so held to be even by his own countrymen, when, through the information of the honourable Mr. Cavendish, they were made acquainted with Mr. Harriot's book: Sixthly, There are some little changes, particularly in the marks made use of by Des Cartes, and which were never followed by any body, that plainly intimate he only introduced them in order to disguise: Seventhly, It appears that Des Cartes himself was acquainted with the charge brought against him on this head, and yet he never thought fit to justify himself, nor ever so much as declared, that he never had seen the book he was said to have copied.

On the whole, therefore, there is all the reason in the world to believe, that the honour due to the great improvement of this science, which fitted it for all that it has received since from foreigners or Englishmen, belongs to our author Harriot, and not to Des Cartes, who only accommodated these discoveries to geometrical subjects.

After him Dr. John Pell published some new discoveries, while he was resident for the commonwealth of England in Switzerland. The method he took of doing it was this; he recommended to Mr. Thomas Brancker a Treatise of Algebra, written in the German language by Rhonius, which when he had translated, the Doctor revised, altered, and added to it. In this piece there are a great many curious things, relating especially to Diophantine algebra, but delivered very obscurely, in such a manner that Dr. Wallis seems to be in a doubt, whether himself had reached Dr. Pell's true meaning. Yet to this gentleman, who wrote in so per-

plexed a way, we stand indebted for the invention of the register; a method of great use, especially to beginners, the practice of which chiefly recommended Kersey's Algebra. As for the rules of John Van Hudde, Mr. Mërry, Erasmus Bartholine, Mr. Huygens, and others, we shall not take notice of them, because, in reality, they are no more than improvements and deductions from Harriot. The same thing may be said of what has been written by Messieurs Fermat, De Billy, Fernelle, and other French mathematicians, who only proposed problems for other people to resolve, and reserved their own method of solutions as impenetrable secrets. Dr. Wallis has made some considerable improvements in this science; especially in respect to impossible roots in superior equations; and what he left imperfect has been supplied by the ingenious Mr. Abraham de Moivre, whose accurate performances on that subject have lately been published in the Algebra of Dr. Saunderson.

In 1655, Dr. Wallis published his *Arithmetica Infinitorum*, in which he squared a series of curves, and shewed, that if this series could be interpolated in the middle spaces, the interpolation would give the quadrature of the circle.

This treatise fell into the hands of the ingenious Sir Isaac, then Mr. Newton, in the year 1664, when that gentleman was about twenty-two years of age; and he, by a sagacity peculiar to himself, derived from this hint his celebrated method of infinite or converging series. In 1665, he computed the area of the hyperbola by this series, to 52 figures; which having communicated to Dr. Barrow, he prevented Mr. Nicholas Mercator's running away with the reputation of this discovery, who in 1668 published the quadrature of the hyperbola by an infinite series. This was received with universal applause; and yet Mr. Newton far exceeded him, since, without stopping at the hyperbola, he extended this method by general forms to all sorts of curves, even such as are mechanical, to their quadratures, rectifications, and centers of gravity, to the solids formed by their rotations, and to the superficies of those solids; so that supposing their determinations to be possible, this series stopped at a certain point, or at least their sums were given by stated rules. But if the absolute determinations were impossible, they could yet be infinitely approximated, as he likewise shewed; and which, as a French writer justly observes, is the happiest and most refined contrivance for supplying the defects of human knowledge, that man's imagination could possibly invent. It is also certain, that he attained his invention of fluxions by the time he was four and twenty; but his modesty was so great, that he forbore to publish his discovery; which was the sole reason that the honour of it was ever disputed with him. In

1707, he first published a system of algebra, under the title of Universal Arithmetic; and in 1722, gave another edition of it, wherein are contained all his improvements in that art. From the rules laid down by him, still farther lights were struck out by succeeding mathematicians, such as Dr. Edmund Halley, who published in the Philosophical Transactions a method of finding the roots of equations without any previous reduction, and the construction of equations to the third and fourth power, by the help of the circle and parabola. Mr. John Colson, who obliged the world with an universal resolution, geometrical and mechanical, of cubic and biquadratic equations; Mr. Colin MacLaurin in his treatise of Impossible Roots; Mr. Simon of Woolwich, Mr. Clark, and some others, have applied algebra likewise to the laws of chance and gaming, as may be seen in the excellent treatises they have written on that subject.

NUMERAL ALGEBRA is that wherein the unknown quantities are represented by letters, or symbols, and the known quantities by numbers.

This kind of algebra is what was used by the ancients, till the time of Franciscus Vieta, (who was the first that invented literal or specious algebra) and is sometimes now used by young students in the science, who cannot without some difficulty and practice make themselves familiar with the algebraic language; and therefore, by this mixture of numbers and letters, they gradually become acquainted with the true value of letters, which may represent either known or unknown quantities.

LITERAL or SPECIOUS ALGEBRA, is that wherein both the known and unknown quantities are represented by letters or symbols, by which means we have general solutions instead of particular ones, as well as raise theorems, and demonstrate all kind of problems, whether arithmetical or geometrical.

For the method of working the several rules in algebra, they will be treated of under their respective articles. See ADDITION, SUBTRACTION, MULTIPLICATION, DIVISION, &c.

ALGEBRAICAL, any thing that belongs or relates to algebra; thus we say, algebraic curves, solutions, characters, symbols, &c. See CURVE, &c.

ALGEBRAIST, one who understands and is well acquainted with algebra.

ALGENEB, a star of the 3d magnitude, on the right side of Perseus. It is the 33d in that constellation, according to Flamsteed's order, and marked α by Bayer. This star, by most astronomers, is said to be of the second magnitude, but by observation, it is found to be only of the third. For its right ascension, declination, &c. see the constellation PERSEUS.

ALGOIDES, a name used by Vaillant for a

genus of plants, called, by Linnæus, zannichellia. See ZANNICHELLIA.

ALGOL, a fixed star of the 3d magnitude, called also Medusa's head; it is the 26th of Perseus, according to Flamsteed's order, and marked β by Bayer. See the constellation PERSEUS.

ALGORAB, in astronomy, a star of the 3d magnitude, in the right wing of Corvi; it is the 7th according to Flamsteed's order, and marked γ by Bayer. See the constellation CORVUS.

ALGORITHM, sometimes called *logistica numeralis*, is an Arabic term frequently used to signify the practical rules in algebra, but more commonly, the five principal rules in arithmetic, namely numeration, addition, subtraction, multiplication, and division.

ALGUAZIL, in the Spanish police, an officer whose business it is to carry the decrees of the judges into execution.

ALHEAL, in botany. See PANAX.

ALHIDADE, or **ALIDADE**, an Arabic name for a label, index, ruler, &c. which is moveable about the center of any arch; especially in mathematical instruments, used in taking heights and distances. These alidades are of different kinds; thus the plumb-line of a Gunter's quadrant, the index of a Hadley's quadrant, and the eight feet refracting telescope on the mural arch at Greenwich, &c. are what the Arabian writers of mathematics called alidades; but it is a term seldom made use of at present.

ALIAS, a second or further writ issued from the courts of Westminster, after a capias, &c. sued out without effect.

ALIBI, in law, implies the absence of the accused party; or his being at a distance from the place where the fact was committed, at the very time mentioned in the indictment.

The word is Latin, and properly signifies elsewhere.

ALIEN, in law, implies a person born in a strange country, not within the king's allegiance, in contradistinction to a denizen, or natural subject.

The word is formed from the Latin, *alius*, another; q.d. one born in another country.

An alien is incapable of inheriting lands in England, till naturalized by an act of parliament. No alien is entitled to vote at the election of members of parliament; nor can he enjoy any office, or be returned on any jury, unless where an alien is party in a cause, when the inquest is composed of an equal number of denizens and aliens.

Some have thought that the laws against aliens were introduced in the time of Henry II. when a law was made at the parliament of Wallingford, for the expulsion of strangers, in order to drive away the Flemings and Picards, introduced into the kingdom by the wars of king Stephen. Others

have

have thought that the original of this law was more ancient; and that it is an original branch of the feudal law; for by that law no man can purchase any lands, but he must be obliged to do fealty to the lords of whom the lands are holden; so that an alien that owned a previous faith to another prince, could not take an oath of fidelity in another sovereign's dominions.

ALIEN-DUTY, an impost laid on all goods imported by aliens, over and above the duty for such goods imported by British subjects, and on British bottoms.

ALIEN-PRIORIES, a kind of inferior monasteries, formerly very numerous in England, and so called from their belonging to foreign abbies.

ALIENATION, in law, implies the act of making over a person's property in lands, tenements, &c. to another.

ALIFORMIS, in anatomy, the name of a pair of muscles arising from the pterygoide bones, the process of the os cuneiforme, with a beginning partly nervous, and partly fleshy, and ending in the neck of the lower jaw.

ALIFORMIS PROCESSUS, a name sometimes given to the prominence of the os cuneiforme.

ALIMENT, in a general sense, implies whatever contributes to the nourishment of an animal or vegetable body.

ALIMENT, among physicians, whatever is capable of nourishing an animal body.

The loss we sustain daily makes it necessary that it should be repaired by substances analogous to those of our body, such as aliment and drink, the stimulus to which is hunger and thirst.

Experience has sufficiently demonstrated, that the best method of preserving health is to live upon plain simple aliment, lightly seasoned, and in quantity agreeable to the age, strength of the stomach, season of the year, sex, constitution, and chiefly to what nature has found by experience to require: for it is as great a fault to take too much as too little. Perfect digestion is the best rule for regulating a meal, especially if the person is more brisk and lively after a repast than before.

We have examples of many persons, who by their temperance have lived to a very advanced age; wherefore, those that are fond of life and health should imitate their regimen. Excesses in eating and drinking are extremely pernicious.

Persons of a delicate constitution, or who are just recovered from a disease, should use soft light aliments agreeable to the stomach; for they make the best chyle.

Acid, tenacious, viscous aliment, pies of all kinds, things that are fat, and of a blackish substance, are generally unfit for chylification, or render the chyle bad.

Strong, robust, young persons, who use much exercise, ought to eat more than others; and may

be more free with the grosser kind of aliment; for their stomachs being strong, the lighter kind of food would digest too easy, and be dissipated too soon.

Children whose stomachs are weak, and vessels fine, ought to use a light, slender, thin, soft aliment, easy of digestion; wherefore infants should be fed with fluid milk, to avoid causing obstructions in their fine and delicate vessels. Consequently, the milk of a nurse newly brought to bed is more agreeable to infants, than that of one who has been delivered five or six months, and whose milk begins to have too great a consistence. Nurses should observe an exact regimen, and shun all sorts of violent passions; for they disturb digestion, and communicate their bad effects to their children. When infants are weaned, they should not be accustomed to spirituous liquors and strong food, especially the salt and smoke-dried, which are hard of digestion, and yield bad nourishment. The best method is to eat little at a time and often.

In old age the fluids are more thick, the secretions slow, and the solids more stiff than in youth; wherefore they require less food, and in a more soft, nourishing, moistening kind, easy of digestion, and not too much at a time, especially in the evening.

At all times of life, but especially in old age, the constant and immoderate use of salt and smoke-dried meat, acid and aromatic vegetables, as well as spirituous liquors, tend to harden and stiffen the parts of the body, instead of affording good nourishment; besides, the digestion of these aliments is difficult, and render the blood so acrid, as to hurt the capillary vessels.

However, an acquired habit is hard to be left off, and we find many persons enjoy a good state of health when their meat and drink are very indifferent, because they are become customary, and they are apt to fall sick when they attempt to change their manner of life; for custom is a second nature: all great changes ought to be brought about insensibly.

For this reason, it is good not to contract a habit of any kind; wherefore, persons of a good constitution should live in a various manner, and refuse no kind of aliment; and should sometimes be in town, and sometimes in the country; should use much exercise, and should even now and then exceed the exact bounds of moderation, and at other times omit a meal now and then.

Hunger shews the best time of eating, but custom confines us to certain hours. Persons who find no inconvenience from dining and supping every day, need not change their manner of life. In youth, wherein there is a great dissipation, and in age, where strength is wanting, and when little is eaten at a time, something taken between meals

is not amiss. However, it is necessary to observe, that when the stomach is bad, persons should not begin to eat again till the last meal is digested.

When a person is greatly fatigued, and his spirits dissipated, it will be necessary to rest before eating. In cases of distress and sorrow, the aliment should be very light, and small in quantity, because the stomach is weak at those times.

In the summer, when the spirits and fluid parts are apt to evaporate, the aliment should be light, moist, fluid, and easy of digestion, to repair the loss with greater speed; whereas in winter the stomach will admit of grosser food.

ALIMENTARY, an epithet applied to whatever belongs to aliment or food.

ALIMENTARY Duct, in anatomy, a name given by some to the intestines, on account of the aliments passing through them.

ALIMENTARY Duct is also sometimes used for the thoracic duct. See **THORACIC Duct**.

ALIMONY in law, implies that allowance which a married woman sues for, and is entitled to, upon any occasional separation from her husband.

The word is Latin, *alimonia*, and properly signifies nourishment or maintenance.

ALIQUNT Part, in arithmetic, is a number that cannot measure a given number, or cannot divide a given number without leaving a remainder; thus, 5 is an aliquant part of 17; 4 of 9: 3 of 5, &c. but that these aliquant numbers cannot measure any numbers, (as is said in some books of this kind) is absurd, for 5 will measure 10, 15, 20, &c.

ALIQUNT Parts, in arithmetic, are such as will measure or divide a given number, without any remainder; as 5 will divide 10, 20, 25, &c. 7 will divide 14, 21, 28, 35, &c. these therefore are called aliquot parts of the above numbers.

The aliquot parts of a pound are the following:

10s.	make one	half	of	20s.
5	-	-	fourth	- - -
4	-	-	fifth	- - -
2	-	-	tenth	- - -
1	-	-	twentieth	- - -
6s. 8d.	- -	-	third	- - -
3 4	- -	-	sixth	- - -
2 6	- -	-	eighth	- - -
1 8	- -	-	twelfth	- - -
1 4	- -	-	fifteenth	- - -
1 3	- -	-	sixteenth	- - -
0 10	- -	-	twenty-fourth	- - -
0 5	- -	-	a forty-eighth	- - -

The rule for finding all the aliquot parts of any number, is, Divide the given number by its least divisor, and that quotient by its least divisor, until you get a quotient that is not divisible, and you will have all the prime divisors, or aliquot parts of that number; then if every two, three,

four, &c. be multiplied into themselves, the products will be the several conjoined divisors, or aliquot parts of that number. For multiplication and division of aliquot parts, see **MULTIPLICATION and DIVISION of Aliquot Parts**.

ALKAHEST, or **ALCAHEST**, among chemists, implies an universal solvent, or a menstruum that will dissolve all bodies without exception.

The word seems to have been coined by Paracelsus, it being derived from no language, and was unknown before the time of that author.

Paracelsus, and the elder Van Helmont, have expressly declared in their writings, that there is a certain fluid in nature, capable of reducing all sub-lunary bodies, as well homogeneous as mixed, into their ens primum, or original matter whereof they are composed; or into an uniform, equable, and potable liquor, that will unite with water, and the juices of our bodies, yet retain its feminal virtues; and if mixed with itself again, will thereby be converted into pure elementary water: whence they imagined this menstruum could at length reduce all things to water, whilst, itself, was incapable of any farther change. Such a declaration as this, seconded by the asseveration or oath of Helmont, who religiously swears himself possessed of the secret, caused all the succeeding chemists solicitously to turn their thoughts and labours to find out such a noble menstruum. And the famous Mr. Boyle was so fond of it, that he frankly acknowledges he had rather have been master thereof than of the philosopher's stone; as indeed, it were a thing more to be wished for than the power of transmuting metals. That great philosopher, however, ingeniously tells us, he had not the good fortune to possess it.

Now it is easy to conceive, that all bodies might originally grow from some first matter, which was once in a fluid form. Thus the primitive matter of gold is, perhaps, nothing more than a ponderous fluid; which, from its own nature, or a strong attraction between its parts, afterwards acquires a solid form. The assertion, therefore, of Paracelsus and Helmont carries a shew of probability with it, when they say there is some universal ens, or original matter, that resolves all bodies into their ens genitale, or the primitive substance whereof they were at first created. So many are the authors who have treated of this subject, that a library might almost be collected of the books written upon the alkahest. Weiderfelt, in his treatise *De Secretis Adeptorum*, has made a collection of all the opinions that have been entertained about it; but it is manifest from his writings, that he himself never saw the thing. Pantaloon also, with Philalethes, Tachenius, Ludovicus, and a thousand others, treat of the same subject. But none of them speak to the purpose, nor declare themselves possessed of the secret, except Paracelsus and Helmont, who are the

the original authors, and upon whose writings the rest have made idle comments, or fallen into some whimsical conceit as to this grand solvent.

But notwithstanding their pretensions, the principal chemists are now persuaded that no such solvent ever existed in nature: at least, that no mortal was ever possessed of the secret. This, indeed, seems sufficiently evident from the very nature of the alkahest; for if it will dissolve all bodies, it will be impossible to be kept in any vessel. Van Helmont therefore cannot be believed, when he asserts that he had a bottle filled with alkahest lent him; because it could not be contained in any bottle, as it would dissolve the vessel and be lost.

ALKALI. See the article **ALCALI**.

ALKANET, in botany, the English name of a genus of plants called anchusa. See **ANCHUSA**.

ALKEKENGI, the winter cherry, in botany, a plant with perennial roots, from which in the spring, the stalk arises to about a foot high, furnished with heart-shaped leaves standing in pairs; the flower produced from the wings of the stalk is monopetalous, divided at the extremity into five segments; in the center is placed a round germin, supporting a slender style, accompanied by five filaments, topped with oblong upright anthers, which join together; this is succeeded by a globular berry, covered by an inflated empalement, containing a number of kidney-shaped seeds. The fruit ripens in autumn, and in colour and shape much like a cherry; if the season is mild, will continue to the latter end of the year, afterwards the plant dies to the ground.

The fruit of this plant is by some much celebrated for their lithontriptic qualities, and are said powerfully to cleanse the urinary passages of all gravel, and whatever is apt to obstruct them, and likewise by their detensive qualities, to be good in the jaundice, and other affections of the viscera. The berries boiled in milk, and sweetened with sugar, cure the heat of urine, the making bloody water, and ulcers in the kidneys or bladder.

There are various sorts of the alkekengi, which are all called by Linnæus *physalis*.

ALKERMES, a compound cordial medicine, formerly much in use, the principal ingredient of which is kermes. See **KERMES**.

ALKORAN. See **ALCORAN**.

ALLA, or **ALLAH**, the name of God among the professors of the Mahometan religion. It properly signifies the adorable Being.

The word is Arabic, and derived from *alah*, to adore.

ALLANTOIS, or **ALLANTOIDES**, in anatomy, a vesicle investing the fetus of several animals, and containing an urinous liquor, supposed to be conveyed thither from the urachus.

The word is Greek, and compounded of *αλλαν*, a gut, and *ειδης*, resemblance.

Anatomists are not agreed whether the allantois has or has not any existence in the human species.

ALLAY. See the article **ALLOY**.

ALLEGATION, in law, implies the producing instruments, or deeds, for proving the truth of something litigated before the court.

ALLEGIANCE, in law, signifies the obedience which every subject owes to his lawful sovereign.

The word is formed from the Latin *allegiantia*, and derived from *allego*, to admit.

Allegiance is either natural, acquired, or local.

Natural **ALLEGIANCE** is that which every subject born ought to pay immediately upon his birth.

Acquired **ALLEGIANCE** is that which a person naturalized, or made a denizen, owes to the king.

Local **ALLEGIANCE** is that which a person, on his entering the dominions of another prince, ought to pay for his protection.

Oath of **ALLEGIANCE** is that taken by the subject, and in which he acknowledges the king a temporal prince.

ALLEGORICAL, something belonging to, or partaking of, the nature of an allegory. See **ALLEGORY**.

ALLEGORICAL Poetry is that where some useful moral is conveyed under the veil of fiction and allegory. The most beautiful poem of this kind in ours, or perhaps in any other language, is Spenser's *Fairy Queen*.

This species of poetry allows the largest scope and latitude to the genius: the fancy of the poet, winged with the wildest enthusiasm, may fly out beyond the bounds of space and time; it may give to airy nothing a local habitation and a name. Not contented with *bodying forth* the virtues, vices, passions, and all natural and moral qualities; it may dart into the fairy-land of fiction; and with more than magic power conjure up a new creation of monstrous dragons, enchanted castles, and tremendous giants. Yet *rolling in this fine frenzy* the eye of the poet must still watch the moral: however wild and romantic his inventions are, the mystical meaning of his fable must appear under the veil distinct and intelligible. It is this, and this only, which can justify him, when he transports us, beyond the bounds of nature, into that ideal country, whose inhabitants are all apparitions, whose very rocks have voice and language, and whose trees drop tears of blood.

Having thus given the reader a short sketch of the general meaning of allegorical poetry, it may not be amiss to mention four qualifications, which appear to be necessary to this sort of composition.

The first is, that the fable must be lively and surprising, in order to raise and engage our curiosity.

curiosity. As there is more invention therefore employed in a work of this kind than in mere narration, or description, or indeed than in general amplifications on any subject whatever, it consequently requires a more than ordinary heat of fancy, when the subject is first struck off the anvil. If the fable is flat, spiritless, and uninteresting, the reader's imagination is not affected, nor his attention engaged, though the instruction conveyed under it be ever so useful or important.

The second qualification is a beautiful propriety or aptness in the fable to the subject on which it is employed. The invention of the poet should never lose itself in a confusion of ill-sorted ideas, nor, aiming only to surprize the imagination, offend the judgment. As it requires a heat of fancy to raise images or resemblances; so it requires a good taste to distinguish and range them, and to chuse the most proper and beautiful, where there appears an almost distracting variety.

Another essential property is, that the fable be every where consistent with itself. As licentious as allegorical poetry may seem in some respects, it is nevertheless subject to this restraint. The poet is indeed at liberty in chusing his story, and inventing his persons; but after he has introduced them, he is obliged to sustain them in their proper characters. *Sibi consent*, is a rule that ought never to be violated: for however extravagant his characters may be, they should never be absurd.

The three qualifications mentioned above, respect the fable of the poem; the last property relates to the moral, and is, that the allegory should be clear and intelligible; for the fable is designed only to clothe and adorn the moral, not to hide it. The poet should in this respect imitate the art and skill which is shewn by the old and celebrated masters of statuary; who in composing an animated figure, considered the situation of every limb, muscle, and vein, which they finished with the utmost exactness; and then afterwards put on the drapery in such an easy and natural manner, that instead of hiding, it contributed to discover the beautiful symmetry of the parts over which it was thrown.

ALLEGORIST, one who writes in, or has recourse to allegories.

ALLEGORY, is the name given to a fable or story, in which, under imaginary persons or things, is shadowed some real action, or instructive moral: it is, according to Plutarch's definition, that in which one thing is related, and another understood. Every allegory therefore must be considered as having two meanings, the literal and the mystical: the literal sense is like a dream or vision, of which the mystical sense is the true interpretation.

If we pursue this point still further, we shall find, that as a simile is nothing but a continued metaphor, so an allegory is only a continued

simile. It may not be amiss to illustrate this by an example: "The *helm* of state was under the management of Cato." This is simply a metaphorical expression, by which the state is in one word compared to a ship: if we say further that, "As the wary pilot steers the ship secure from all the rocks and shelves, that lie in wait to destroy it; so Cato preserved the state from every intricate and plot that threatened its destruction;" we then continue the metaphor into a simile; which if pursued still further will become an allegory, as we see in that excellent ode of Horace,

*O novis referent in mare te novi
Fluctus!*

We meet with nothing in the whole ode, that is not strictly applicable to a ship; and yet it is universally agreed, that the thing signified is the Roman state. Considered in this light, tides and tempests are wars and civil broils; the port is peace and concord; the sails are the laws; the magistrates are the mariners; and the rocks and shallows are those dissensions that may tear and distract it.

The more immediate uses of allegory seem to be these; to render Virtue more amiable, by cloathing her in the gay and ornamental robes of Fiction, and Truth more engaging, by making her fly from before us, and raising a strong curiosity in us to pursue and overtake her. The Virtues, in allegory, are personified, and employed in great and interesting adventures; they present themselves to us in the most alluring manner, adorned not only in native loveliness, but in all the graces of action; we are charmed with their beauty, and cannot help interesting ourselves in their welfare; they enlist the passions on their side, and we follow them through all their difficulties, till at last they arrive at the end that was proposed, and are crowned with success. It does not signify that we know it is all a fiction; we enter willingly into the deceit, when an air of probability runs through the story, and event follows event in a regular and natural succession. Rules of morality are dull and uninteresting; they may indeed instruct, but seldom entertain us: nay, even truth itself is more engaging when pursued, than when possessed; like eager sportsmen we follow the chace with unwearied pleasure, but when once the game is hunted down, we trouble ourselves little further about it. It was for this reason that *parables* are frequently interspersed in the New as well as Old Testament. Composed of probable, yet at the same time of fictitious events, they raise our curiosity, and engage our imagination; by which means the moral that they are intended to convey, steals upon us imperceptibly, and we find either our hearts improved, or our understandings enlightened. When Nathan the Prophet was sent

ALL

to reprove David for the murder of Uriah, and his adultery with Bathsheba; we cannot help admiring the art and address with which he executed his commission. He did not attack the king with old canting saws and lessons of morality; did not expatiate on the heinousness of the crimes which he had committed, and the necessity there was for a hearty and sincere repentance: no; he took a more effectual method, by concealing his design under the veil of an allegory or parable. He began a simple and pathetic story, that awakened the attention and curiosity of the king; he touched the secret springs and movements of his soul; called up on one hand his tenderness and pity, and on the other his anger and indignation: "As the Lord liveth, said David, the man that hath done this thing shall surely die!" Before he was convicted, he was self-condemned; and when Nathan retorted upon him, "Thou art the man," could not fail of being overwhelmed with remorse and confusion.

ALLEGRO, in music; an Italian word, signifying that the part is to be played in a brisk, gay, and sprightly manner.

ALLELUJAH is an expression of joy or praise, made use of in several parts of the holy scripture. It is compounded of the two Hebrew words, הללו *hallelu*, and יהוה *jab*, which is an abbreviation of יהוה *Jeheboah*: its literal meaning is, *Praise the Lord*.

ALLERION, in heraldry, a sort of eagle, without beak or feet, having nothing perfect but the wings.

ALLEVEURE, a small brass Swedish coin, worth about $2\frac{1}{2}$ d. English.

ALLEY, in gardening, a straight walk bounded on both sides with trees or shrubs, and commonly covered with gravel or grass. An alley is distinguished from a path, by being broad enough to admit two persons to walk a-breast, whereas a path is supposed to admit of but one at a time; but if an alley is wider than ten or twelve feet, it may, with more propriety, be called a walk.

Covered ALLEY, is where the trees on each side meet at the top, so as to form a shade.

ALL-HEAL, in botany. See **PANAX**.

ALLIANCE, in the civil and canon law, implies the relation between two persons, or two families contracted by marriage.

ALLIANCE is also used to signify a treaty entered into by sovereign princes or states, for their mutual safety or defence.

Defensive ALLIANCE is that whereby the contracting parties engage to stand by and assist each other against any power that shall attack either.

Offensive ALLIANCE implies an agreement between powers, whereby they engage themselves to attack jointly some other prince or state.

ALL

ALLIGATION, in arithmetic, is that rule by which we resolve questions that concern the mixing or uniting divers simples or particulars into one mass or sum, according to any price or sum required.

The word is formed from the Latin, *alligare*, which signifies to tie together; perhaps from a sort of vincula or curve, commonly used to connect or join the several quantities or numbers together.

Alligation is either *medial* or *alternate*.

ALLIGATION medial, is, when having the several quantities and rates of divers simples proposed, we discover the rate of a mixture compounded of those simples. All questions in this may be solved by the following rule.

Having the quantity of the ingredients and the particular prices, to find the price of some part of the mixture.

RULE.

Multiply the ingredients severally by their own prices, and divide the sum of those products by the sum of the ingredients, and the quotient answers the question.

EXAMPLE.

A Tobacconist would mix 20 lb. of tobacco, at 9 pence the pound, with 60 lb. at 12 d. with 40 lb. at 18 d. and with 12 lb. at 2 s. the pound. Place the numbers of their value as follows:

lb.	s.	d.	£.	s.	d.
20	at	0 9	per lb.	will cost	0 15 0
60	at	1 0	- - - -	- - -	3 0 0
40	at	1 6	- - - -	- - -	3 0 0
12	at	2 0	- - - -	- - -	1 4 0

Sum simple 132 Total value 7 19 0

Therefore $7l. 19s. \div 132 = 1s. 2\frac{1}{2}d.$ = the value of one pound.

ALLIGATION alternate, is when the rates or qualities of divers simples are given, and the quantity of each is required, necessary to make a mixture of the given rate or quality; it likewise shews the proportion of several ingredients, and counterchanges the places of such excesses or differences as arise between the mean price and the extremes; ascribing that to the greater extreme which comes from the lesser, and contrarily. To resolve questions in alligation alternate, observe the following rules.

First, when the prices of the simples are expressed, but no quantity given, and it is required how much of each simple we must take to sell one quantity or measure at a mean rate propounded;

RULE.

Link the extremes together, and take the difference between each number and the mean rate propounded,

ALL

ALL

pounded, and place that difference against its yoke-fellow, which will be the quantity required of that yoke-fellow in this mixture.

EXAMPLE.

A Merchant hath spices, some at 9 d. per pound, some at 12 d. some at 24 d. and some at 30 d. per pound; how much of each sort must he take, that he may sell a pound for 20 d.

Link the numbers together in the following manner:

Price proposed 20 d.	$\left\{ \begin{array}{l} 9 \\ 12 \\ 24 \\ 30 \end{array} \right\}$	$\begin{array}{l} 10 \\ 4 \\ 8 \\ 11 \end{array}$
----------------------	---	---

The difference between 9 and 20 = 11, which is placed against its yoke-fellow 30, which denotes that 11 pounds is to be taken off that at 30 d. per pound, to make the mixture: the difference between 12 and 20 is 8, which place against its yoke-fellow; likewise between 24 and 20 is 4, and 30 and 20 is 10, which place in their proper places, as in the example above, and the work is done; for the numbers 10, 4, 8, and 11, are the quantities of each required.

Note, That as many different ways as the numbers can be linked together, so many different answers will be given, and yet all true.

Second, when the price of all the simples, and the quantity of one is given, to find the quantity of all the rest, so as one measure or quantity may bear a mean rate or price propounded.

RULE.

As the difference standing against the quantity given:
To the rest of the differences besides : :
So is the quantity given :
To the quantity sought: each to its respective difference.

EXAMPLE.

A Tobacconist hath 30 lb. of tobacco at 24 d. per pound, which he would mix with some at 12 d. per pound, some at 9 d. and some at 7 d. per pound; and he would know how much of each sort of the said less prices, must be mixed with the 30 lb. of the best, that he may sell it at a penny the ounce, or for 16 d. per pound.

First, set down the numbers, link them together, and take the differences, as in the last example. Thus,

$\left\{ \begin{array}{l} 24 \\ 12 \\ 9 \\ 7 \end{array} \right\}$	$\begin{array}{l} 4, 7, 9, \\ 8 \\ 8 \\ 6 \\ 8 \end{array}$	$\begin{array}{l} 20, 30 \\ 8 \\ 6 \\ 8 \end{array}$
--	---	--

Then say, As 20, the difference against the quantity given : to 8 the next difference : : so 30 : to 12, the quantity required at 12 d. per pound.

And seeing the other differences are equal, it will require 12 lb. of each.

Third, When the prices of each simple is given, and the mean rate or price, and it is required to find how much of each sort must be taken, to make a certain quantity propounded, agreeable to the mean rate given.

RULE.

As the total sum of the differences :
Is to the total quantity given : :
So is any particular difference :
To its particular quantity sought.

EXAMPLE.

A Grocer hath four sorts of currants, one at 4 d. the lb. one at 6 d. one at 9 d. and the best at 11 d. the lb; he would mix 240 lb. and to have so much of each sort in this mixture, as to sell a pound for 8 d; how much of each sort must he take?

Place your numbers with the mean price, linking them, and take their difference as follows:

$\left\{ \begin{array}{l} 4 \\ 6 \\ 9 \\ 11 \end{array} \right\}$	$\begin{array}{l} 3 \\ 1 \\ 2 \\ 4 \end{array}$	$\begin{array}{l} 72 \\ 24 \\ 34 \\ 96 \end{array}$
		10 240

Then say,

As 10 : 240 :: 3 : 72 the quantity at 4 d. per lb.
10 : 240 :: 1 : 24 D^o. - - - 6 d. D^o
10 : 240 :: 2 : 48 D^o. - - - 9 d. D^o
10 : 240 :: 4 : 96 D^o. - - - 11 d. D^o

ALLIGATOR, in natural history, an amphibious creature common in South-America, supposed by some authors to be the same with the crocodile found in Asia and Africa. Its head is long, and slender towards the extremity, gradually forming a snout like that of a hog. Both the upper and lower jaws have a row of very strong and pointed teeth.

ALLIOTH, in astronomy, a fixed star of the second magnitude, in the tail of the great bear. For its right ascension, declination, &c. see the constellation **URSA MAJOR**.

ALLIUM, garlick, in botany. See **GARLICK**.

ALLOCATION, an allowance made upon account in the Exchequer.

ALLOCATIOE Facienda, a writ for allowing to an accountant such sums of money as he has lawfully expended in his office; directed to the lord-treasurer, and barons of the Exchequer.

ALLOCATO Comitatu, a new writ of exigent allowed before any other county-court, held on the former not being fully served or complied with.

ALLO-

ALM

ALLODIAL, an epithet applied to an inheritance held without paying any acknowledgment to either lord or superior.

The word is formed from the Saxon, *a* privative, and *loef*, lord; *q. d.* held without a superior.

Allodial lands are what we term free lands, which a person enjoys without paying any fine, rent, or service.

ALLODIUM, free lands, or such as are the absolute property of their owner, without his being obliged to pay any acknowledgment whatsoever.

ALLOM. See the article **ALUM**.

ALL-SAINTS, a festival celebrated by the Christian church on the first of November, in commemoration of all the saints in general.

ALL-SOULS, a Christian festival kept on the second of November, in commemoration of all the faithful deceased.

ALLOY, or **ALLAY**, a proportion of a baser metal with one that is finer.

All gold coin has an alloy of silver, and silver coin an alloy of copper. A pound weight of standard gold, by the present standard of the mint, is two and twenty carats fine, and two carats alloy; and a pound weight of standard silver consists of eleven ounces two penny weights of fine silver, and eighteen penny weights of alloy. And in proportion as gold or silver has more or less alloy than that above-mentioned, it is said to be coarser or finer than the standard.

ALLUMINOR, a person who colours or paints upon paper or parchment.

The word is derived from the French *allumer*, to lighten.

ALLUSION, in rhetoric, a figure by which something is applied to, or understood of another, on account of some similitude between them.

ALLUVION, among civilians, denotes the gradual increase of land along the sea-shore, or on the banks of rivers.

ALMACANTERS, **ALMACANTARAS**, or **ALMACANTARATHS**, in astronomy, are circles of the sphere parallel to the horizon, imagined to pass through all the degrees of the meridian, and are the same thing with regard to the azimuths and horizon, that the parallels are with regard to the meridian and horizon.

ALMACANTER-Staff, an instrument formerly used at sea to observe the sun's amplitude; it was usually made of wood, and had an arch containing 15 degrees.

This instrument is never used at present, as much better are introduced in its place.

ALMAGEST, an Arabic name for a celebrated book of Ptolemy's composing, being a collection of many curious observations and problems of the ancients in geometry and astronomy.

Ricciolus also published a body of astronomy, which, after Ptolemy, he called the New Alma-

ALM

gest, being a collection of the ancient and modern observations and discoveries in that science.

ALMANAC, a book or sheet of paper, usually containing the months, the days of the month, the festivals, rising and setting of the sun and moon, length of days and nights, equation of time, high-water, and age of the moon, as well as the visible and invisible eclipses of the sun and moon.

Authors differ greatly both with regard to the inventor of almanacs, as well as the etymology of the word, some deriving it from *al* and *manab*, to count; while others think it comes from *almanah*, New-Years gifts, because the Arabian astrologers made presents of their ephemerides the first day in the year. For the method of constructing almanacs, See **CALENDAR**, **EPHEMERIDES**, &c.

Herely of **ALMARIC**, a tenet broached in France by one Almaric, in the year 1209. It consisted in affirming, that every Christian was actually a member of Christ; and that without this faith no one could be saved.

His followers went farther, and affirmed, that the power of the Father lasted only during the continuance of the Mosaic law; that the coming of Christ introduced a new law; that at the end of this began the reign of the Holy Ghost; and that now confession and the sacraments were at an end, and that every one is to be saved by the internal operations of the Holy Spirit alone, without any external act of religion.

ALMENE, in commerce, a weight of two pounds, used in weighing saffron in several parts of the continent of the East-Indies.

ALMOND-TREE, *Amygdalus*, in botany, a genus of trees with rosaceous flowers, producing a large oval compressed fruit, which opened, discovers a nut containing a seed of the same form, the common almond-tree being cultivated in gardens more for ornament than use, it making a beautiful appearance early in the spring when few other trees are out. Every good shrubbery should have a few of these plants interperfed with the others: they are propagated by inoculation on plum suckers, or stocks of almonds raised from the seeds, and are to be met with in every nursery garden.

ALMONDS, the fruit of the almond-tree. There are two kinds, bitter and sweet, of which considerable quantities are imported from Spain, Italy, Turkey, and other places up the Mediterranean, and are much used in confectionary and medicine. The bitter almonds are reckoned aperient, detestive and diuretic, they are therefore recommended in obstructions of the liver, spleen, mesentery, &c. Their expressed oil is much used to soften and deterge the wax out of the ears when stopped up, and some use them as a substitute in making ratifia, they being more easily procured than apricot kernels.

Sweet Almonds are of a soft grateful taste, and are.

are cooling, healing, and nutrimental: in the common medical practice they are much prescribed in emulsions, and are good in all disorders arising from choleric and acrimonious humours; they cool and cleanse the kidneys, giving ease in cholic pains and all irritations of the bowels.—The expressed oil, which is so frequently used, is a safe and good remedy in nephritic pains, and may be given in large quantities, for it not only blunts the sharp points which irritate the membranes, but also relaxes the passages so as very much to favour the expulsion of all such matter; it is also much in esteem with nurses for coliciveness and the gripes in children, and is sometimes used in glysters.

ALMONDS, among lapidaries, signify pieces of rock-crystal, used in adorning branch-candlesticks, &c. on account of the resemblance they bear to the fruit of that name.

ALMONER, an officer appointed to distribute alms to the poor.

Lord ALMONER, or *Lord-high ALMONER of England*, is an ecclesiastical officer, generally a bishop, who has the forfeiture of all deadlands, and the goods of felos de se, which he is to distribute among the poor.

He has also, by virtue of an ancient custom, the power of giving the first dish from the king's table to whatever poor person he pleases, or, instead of it, an alms in money.

ALMUCANTARS. See ALMACANTARS.

ALNAGE, or AULNAGE, the measuring of woollen manufactures with an ell.

It was at first intended as a proof of the goodness of the commodity, and accordingly a seal was invented as a mark that the commodity was made according to the statute; but it being now possible to purchase these seals, they are affixed, whenever the vender pleases, to all cloths indiscriminately, to the great prejudice of our woollen manufactures.

ALNAGER, a public officer, whose duty it is to examine into the assize of all woollen cloth, fix seals upon the various pieces, and collect the alnage-duty for the king.

ALNUS, in botany, the alder-tree. See ALDER-TREE.

ALOOF, at a distance. This is generally supposed to be a term of the marine, and thence to have been transferred into common discourse; but this seems matter of doubt: the reason of this conjecture is probably the resemblance of the phrases, keep aloof, and keep the luff, which is the command of the officer who superintends the ship's course to the man who steers, to direct her stem nearer the wind, or nearer that point of the compass from which the wind blows. If it was really a sea phrase, it appears to have regarded the dangers of a lee-shore, where the pilot might apply it

in the sense commonly understood, that is, “keep aloof,” or keep off!

ALOE, in botany, a genus of plants producing liliaceous flowers, which are each destitute of an empalement, but are composed of a tubulous single corolla, spread open and divided into six segments; at the extremity in the center is placed an oval germen, supporting a single style surrounded by six filaments; its fruit is contained in an oblong capsule, divided into three cells, filled with a number of angulated seeds. There are great variety of aloes, the major part of which are natives of Africa, and of all the different classes of succulent plants, are the greatest ornament to our green-houses. Some sorts produce but trifling flowers, but there is ample amends made in the beauty and singularity of their leaves, which are so very different, that if contrasted together, they appear as though they did not belong to the same genus. These plants are increased from off-sets, which on some sorts grow very plentifully, and should be planted in a poor soil, such as brick, rubbish, &c. in the summer months, and must have but little water till they are well rooted. Where there is convenience to suit, if plunged in a tan-bed in the stove it will facilitate their growth; or they may be stuck in the bark till they are rooted and then potted.—Some sorts that do not so freely increase, it may be necessary to multiply them by cutting the top off, except in some particular sorts, which will not admit of it, which will be a means of producing several young plants around the place of incision, which at a proper season, may be taken off and planted, observing to let them dry a few days to heal their wounds which were caused by separation from their mother-plant; for planting them immediately may be a means of their rotting.—These plants, though most of them will bear being out in the air in summer, yet in cool weather, which sometimes happens, they are apt to have their colour changed, from a fine diversified green to a dusky colour, which makes them appear unsightly; therefore to have them in their greatest beauty, which in most sorts consists in their foliage, they should be under shelter all the year; and though many sorts may be kept in a common green-house, yet if placed on the flue of a stove, or hot-house, they will keep growing all the winter, and several will shew their flowers at a time of year when few plants produce their blossoms; likewise there is not the danger of rotting so much as when placed where there is no fire, for in such a situation they must be kept extremely dry on account of their succulence, and consequently are in a state of inaction during the winter. Botanists enumerate between thirty and forty sorts of aloes, among whom was formerly classed the large American aloë, commonly called so; but as there is a very considerable difference, both in the compo-

nent parts of the flower, as also in the plants themselves, Dr. Linnæus has thought proper to class it as a distinct genus, by the name of agave. This plant is to flow a grower in this climate, that it may, and has been kept sixty, seventy, or eighty years before it produces its blossoms; but when it is arrived to a state for blowing, the flower-stem arises from the center of the plant, and advances with such rapidity in its growth, that in six or seven weeks it will be eighteen or twenty feet high, ornamented with large bunches of flowers of a yellow colour, connected to foot-stalks, in form of an S, which are affixed alternately on the main stem, diminishing in size from about a third upward of the stem to the top. There have several of the common aloes blown in England, which are looked upon as great curiosities: when the flower is gone, the decay of the plant follows, but leaves a number of small plants or suckers to succeed. There are different sorts of these aloes, but the most beautiful is a variety of the common sort, having striped leaves; when this plant is grown to a large size, it makes a most grand appearance.

ALOES, in the materia medica, a bitter, gummy, resinous, inspissated juice, prepared from the leaves of the above species of plants. There are three different sorts of aloes found in the shops, distinguished by the names of *socotorine*, *hepatic*, and *caballine*.

ALOE Socotorina. Socotorine aloes are brought from the island Socotora, in the Indian ocean, wrapt in skins; and obtained from the *aloe socotorina angustifolia spinosa flore purpureo*. This sort of aloes is of a bright surface, and in some degree pellucid, in the lump; of a yellowish red colour, with a purplish cast: when reduced into powder, of a golden colour: It is hard and friable in the winter; somewhat pliable in the summer, and softens betwixt the fingers. Its bitter taste is accompanied with aromatic flavour, but not sufficient to prevent its being disagreeable: the smell is not very unpleasant, and somewhat resembles that of myrrh.

ALOE Hepatica. Hepatic, Barbadoes, or common aloes, are usually brought from Barbadoes; the best sort in large gourd shells; an inferior kind in pots; and a still worse in casks; and extracted from the *aloe diecoridis et alorum*, of Sloan. This is darker coloured than the foregoing, and not so clear or bright. It is generally drier and more compact; though sometimes, especially the cask sort, quite soft and clammy. Its smell is much stronger and more disagreeable; the taste intensely bitter and nauseous, with little or nothing of the aromatic flavour of the socotorine.

ALOE Caballina. Caballine, or horse aloes, are prepared, probably, from the *aloe guineensis caballina vulgari similis sed tota maculata*, and not, as is generally supposed, from the feces of the hepatic; the difference not being in purity, but in quality. It

is easily distinguished from both the foregoing by its strong rank smell: in other respects it agrees pretty much with the hepatic; and is, not unfrequently, sold in its place. Sometimes it is prepared to pure and bright as scarce to be distinguishable by the eye, even from the socotorine; but its offensive smell readily betrays it: and if this alo should be dissipated by art, its wanting the aromatic flavour of the finer aloes will be a sufficient criterion.

Aloes is a stimulating cathartic bitter: taken in sufficient doses to purge effectually, as two scruples or a dram, it occasions commonly a great irritation about the anus, and sometimes a discharge of blood. In smaller doses, as ten or twelve grains, repeated once or twice a day, it not only evacuates the first passages, but attenuates and dissolves viscid humours in the remoter parts; warms the habit, quickens the circulation, and promotes the menstrual and hæmorrhoidal fluxes: its continued use renders the blood sensibly more fluid, as appears on venesection. For a time, in these small doses, it does not act by stool; but at length it produces a gentle looseness, of longer continuance than that occasioned by most other purgatives: hence its utility in habitual costiveness. This stimulating cathartic is particularly adapted to persons of a phlegmatic temperament and sedentary life, to cachectic indispositions, and oppressions of the stomach by viscid crudities contracted from irregularity: in dry bilious habits it is often injurious, immoderately heating the blood, or inflaming the bowels.

This bitter juice is accounted destructive to worms (or to the matter which favours their production) whether taken internally, or applied in plaisters to the umbilical region. It is powerfully antiseptic; and commonly made an ingredient in tinctures and balsams for cleansing and healing wounds or putrid fæces.

Aloes is sometimes taken by itself, sometimes mixed with saponaceous medicines, warmed with aromatics, acuated with pungent materials, combined with the decostruent gums, &c. Many of these kinds of compositions have been received as officinals: a pill, for example, composed of equal parts of aloes and soap, with a proper quantity of thin honey: a powder, of eight parts of aloes, with two of canella alba, or with one of virginian snake root, and one of ginger: a tincture made by digesting five ounces of these powders in five or six pints of mountain wine: pills of four parts of aloes, two of myrrh, and two or one of saffron, made up with syrup of saffron, or of orange peel: vinous and spirituous tinctures of the aloes, with different proportions of the myrrh and saffron, &c.

Among different aromatic materials made trial of, cloves seemed the best adapted for alleviating the offensiveness of the aloes: the committee ap-

pointed by the London college for reforming their pharmacopœia, made choice of canella alba, on account of its not rendering the medicine so hot as the necessary quantity of the clove itself would do, and yet having so much of the clove flavour, as to cover the aloes in a sufficient degree: some commend the casia caryophyllata, or clove bark, as having more of the clove flavour than canella alba, and yet not being very hot. Where volatile spirits are to be joined, a solution of the aloes, in dulcified spirit of sal ammoniac, or in spirit of sal ammoniac made with quick-lime, are very elegant preparations, and require little assistance from aromatics to render them supportable to the palate; the offensiveness of the aloes being greatly abated by the spirit, and the pungency of the spirit sheathed by the aloes; the spirit of sal ammoniac made fixed with alkaline salt, does not dissolve near so much of the aloes as the two abovementioned.

ALOES *Wood*. See XYLOALOE.

ALOEICS, a general name for all medicines, whose basis or principal ingredient is aloes.

ALOGIANS, in ecclesiastical history, a sect of ancient heretics, who denied that Jesus Christ is the logos, or eternal word; and therefore they rejected the gospel of St. John as a spurious production.

The word is Greek, and compounded of α , priv. and $\lambda\omicron\gamma\omicron$, the word.

ALOIDES, in botany. See STRATIOTES.

ALOPECIA, in medicine, implies a falling off of the hair, occasioned either by a defect of nourishment, or a bad state of the humours.

ALOPECURUS, fox-tail grass, in botany, a distinct genus of plants; it produces a triandrous flower, consisting of one hollow valve with a long awn or beard inserted on its back part; near the base the germen is round, supporting two styles, and contains a single round seed in a cover.

ALP, a name given to the bullfinch, in several parts of England. See BULLFINCH.

ALPHA, the name of the first letter of the Greek alphabet, answering to our A.

As a numeral it stands for one, or the first of any thing; hence alpha and omega, being the first and last letters in the Greek alphabet, are used to signify the eternity of God.

ALPHABET, the natural or customary series of the several letters of a language.

The word is formed from *alpha*, and *beta*, the first and second letters of the Greek alphabet.

The number of letters is different in the alphabets of different languages. The English alphabet contains 24 letters, to which if we add *j* and *v* consonant, the sum will be 26; the French 23; the Hebrew, Chaldee, Syriac, and Samaritan, 22 each; the Arabic 28; the Persian 31; the Turkish 33; the Georgian 36; the Coptic 32; the Mus-

covite 43; the Greek 24; the Latin 22; the Slavonic 27; the Dutch 26; the Spanish 27; the Italian 20; the Ethiopic and Tartarian, each 202; the Indians of Bengal 21; the Barabese 19. The Chinese have, properly speaking, no alphabet, except we call their whole language by that name: their letters are words, or rather hieroglyphics, amounting to about 80,000.

ALPHABET is also used for a cypher, or table of the usual letters of the alphabet, with the correspondent secret characters, and other blank symbols intended to render the writing more difficult to be decyphered.

ALPHABET, among merchants, a kind of index, with the twenty-four letters in their natural order, in which are set down the names of those who have open accounts, referring to the folios of the ledger.

ALPHABETICAL, something belonging to, or placed in the order of, the alphabet.

ALPHETA, in astronomy, the name of a fixed star of the second magnitude in the northern crown, and generally called *lucida coronis*. See the constellation CORONA septentrionale.

ALPHONSIN, in surgery, an instrument for extracting bullets out of gun-shot wounds.

This instrument derives its name from the inventor Alphonfus Ferrier, a physician of Naples. It consists of three branches, which are closed by a ring. When closed and introduced into the wound, the operator draws back the ring towards the handle, upon which the branches opening take hold of the ball; and then the ring is pushed from the haft, by which means the branches grasp the ball so firmly as to extract it from the wound.

ALPHONSINE *Tables*, astronomical tables computed by order of Alphonfus, king of Castile: that prince is even supposed to have assisted in the construction.

ALPHOS, among physicians, a disease of the skin, otherwise called *vittigo*, when that membrane is sprinkled, or, as it were covered with white spots. Several authors consider it as a symptom of the leprosy. See the article LEPROSY.

The word is Greek $\alpha\lambda\phi\omicron\varsigma$, a radix in that language, and signifies white.

ALRAMECH, in astronomy, the Arabic name of a star of the first magnitude, commonly called ARCTURUS. See ARCTURUS.

ALSINE, chickweed, in botany, a genus of pentandrous plants. The middle kind called *alsine media*, by C. Bauhine, is the chickweed of the shops, and grows wild in most gardens, and often on dunghills. The flowers which are small and roseaceous, are produced in great plenty from early in the spring till Midsummer. The whole plant may be used medicinally, and is accounted cooling.

ing, and therefore good in fevers, and in consumptions arising from hectic disorders.

ALT in music, a term applied to the high notes in the scale. See GAMUT.

ALTAR, a kind of table of wood, or stone, or metal, elevated above the ground, upon which sacrifices were offered to some deity.

Amongst the Romans the altar was a sort of pedestal, either square or round, or triangular, adorned with sculpture, bas-relievos, and inscriptions, whereon the victims were burnt which they sacrificed to their idols.

The Greeks distinguished two different kinds of altars, one they called *ευσας*, which was the real altar, on which they sacrificed to their gods; the other was termed *εσχατα*, being much smaller, and only a sort of hearth, on which they offered up sacrifices to their heroes.

The heathens had a custom, when they made any solemn vow, to lay hold on the altar; to which Pericles alludes, when he says, "*You may be a friend as far as to the altar*;" as if he had said, you may love your friend so well, as to do any thing but forswear yourself for him. Their altars could not be touched, nor even approached, without sacrilege, by persons who had committed murder, or women who had been defiled. They were the most sacred asylums, as well to the innocent as the guilty, none being forced from them, but those who had committed the most enormous villainies.

Altars are of great antiquity amongst the Jewish nation: Noah when he came out of the ark built an altar, and offered up sacrifices to the Lord: Abraham erected another in Sichem, and one in the plain of Mamre. The altars, which God commanded Moses to make, were of be earth, or rough stones; it being expressly forbidden that they should be hewn. In the tabernacle were two altars; one the brazen altar, which was for burnt-offerings, and the other the altar of incense, made of gold.

ALTAR of Burnt-offerings, was a kind of coffer, made of Shittim-wood, covered with plates of brass: its height was three cubits, and its breadth five cubits. It was placed by Moses to the east, before the entrance of the tabernacle, in the open air, that the fire which was kept upon it continually, might not fully the inside of the tabernacle. At each of the four corners of this altar, there was a spire in the appearance of a horn, wrought out of the same piece of wood with the altar itself, and covered with brass: within the altar was a grate of brass, on which the fire was made; and through this grate fell the ashes, in proportion as they increased upon the altar, and were received below, within a pan, which was placed under it. At the four corners of this grate were four rings and four chains, which kept it up at the four horns of the altar. This altar was portable, and was

carried on the shoulders of the priests, by staves of Shittim-wood, overlaid with brass, and put into rings fastened to the sides of the altar. Such was the altar of burnt-offerings belonging to the tabernacle, erected by Moses in the wilderness: but the altar of burnt-offerings, erected in Solomon's temple, was much larger, being twenty cubits square, and ten high. It was covered with thick plates of brass, and filled with rough stones; and on the east side there was an easy ascent leading up to it.

After the return of the Jews from captivity, and the building of the second temple by Zerubbabel, their altars were in some respects different from those in use before the captivity, being composed of large piles of unhewn stones, thirty-two cubits square at the bottom, and twenty-four cubits at the top. The ascent to this altar was by a gentle rising, thirty-two cubits in length, and sixteen in breadth. See Plate IV. fig. 1.

ALTAR of Incense, was a small table of Shittim-wood, covered with plates of pure gold, one cubit square and two high. At each of the four corners thereof was a horn; round it was a small border, and over it a crown of gold. Every morning and evening the officiating priest offered incense upon this altar: for which end he entered with the smoking censer, filled with fire from the altar of burnt-offerings, into the sanctuary, or holy place, where this altar was fixed over-against the table of shew-bread. The priest, having placed the censer upon it, retired out of the sanctuary. This was the altar which was hidden by Jeremiah before the captivity. See Plate IV. fig. 2.

ALTAR, or Table for the shew-bread, was of Shittim-wood, covered with plates of gold: it had a little border round it, adorned with sculpture, and was two cubits in length, one in breadth, and one and a half in height. It was placed in the sanctuary to hold the shew-bread; which were twelve cakes, made in a square form, having, as it were four faces or sides. The Hebrew term for this sort of bread, signifies literally *bread of faces*. It was called the shew-bread, because it was exposed to public view before the ark: none but the priests could lawfully eat of this bread, which was served up hot on the Sabbath-day; and at the same time the stale ones, which had been exposed during the whole week before, were taken away. The offering of the shew-bread was accompanied with salt and frankincense, which was burnt upon the table, at the time when they set on fresh cakes. Authors are not agreed as to the manner of ranging the cakes of shew-bread upon the table. Some think they were placed in three piles, containing four cakes each; others say, there were but two piles of six cakes. The rabbins tell us, that between every two cakes, there were two golden pipes, supported by forks of the same metal, whose end

rested upon the ground to convey air to the loaves, and hinder them from growing mouldy.

THE ALTAR, which was observed by St. Paul at Athens, dedicated *αγίων θέν, to the unknown God*, has puzzled the most learned commentators, to determine precisely what it was: because it was usual among the heathens to engrave upon their altars the name or proper ensign of the deity, to whom they were dedicated. Some follow the opinion of St. Jerom, who informs us, that the inscription was not exactly as St. Paul relates, but that the words were, "To the Gods of Asia, Europe, and Africa; to the unknown and "strange Gods." Others think that St. Paul proposed to speak of those altars, which were to be seen in several parts of Attica, without any particular inscription, and erected after a solemn expiation of the country, made by the philosopher Epimenides. But it seems to us unnecessary to go in search of foreign and difficult interpretations of this passage, as it may be taken in its plain and literal meaning. Lucian in his *Dialogue*, entitled, *Philopatris*, swears by the *unknown God* of Athens; and adds, "Being come to Athens, and "finding there the *unknown God*, we worshipped "him, and gave thanks to him, with hands lifted "up to heaven." This single authority proves incontrovertibly, that there was an altar at Athens erected to the unknown God, with the very inscription mentioned by the Apostle.

ALTAR, in the modern use of the word, signifies the communion table.

ALTAR, or ARA, in astronomy, a constellation of the southern hemisphere, containing seven stars, whereof five are of the fourth magnitude, and two of the fifth; this constellation is not visible in our climate.

ALTARAGE, the profits which the priest receives on account of the altar.

ALTERANTS, in medicine. See the article ALTERNATIVES.

ALTERATE, in music and geometry. See SESQUIALTERATE.

ALTERATIVES, or ALTERNATIVE medicines, in the healing art, are such medicines as correct the bad qualities of the animal fluids, without occasioning any sensible evacuation.

ALTERCUM, in botany, a name given by some old writers to a plant now called *hyoscyamus*. See the article *HYOSCYAMUS*.

ALTERN-BASE, in trigonometry, is a term used in contradistinction to the true base. Thus, in oblique triangles, when the true base is the sum of the sides, then the difference of the sides is the altern-base; but when the difference of the sides is the true base, then the sum of the sides is called the altern-base.

ALTERNATE, in a general sense, signifies a

term applied to such persons or things, as succeed each other by turns.

ALTERNATE, in botany, is such a disposition of the leaves of some plants, that the first leaf on one side of a branch stands higher than the first on the other side, the second leaf the same, and so continued to the top.

ALTERNATE, in heraldry, is said with regard to the situation of the quarters. Thus the first and fourth quarters, and the second and third, are usually of the same nature, and are thence called alternate quarters.

ALTERNATE *Angles*, in geometry. See ANGLES.

ALTERNATE *Ratio*, is the ratio of antecedent to antecedent, and consequent to consequent, in any proportion. Thus if $A : B :: C : D$. then will the ratio of A to C, be as the ratio of B to D, which is alternate; hence this kind of proportion can only take place when the quantities are of the same kind.

ALTERNATION properly signifies a succession by turns.

ALTERNATION of *Quantities* is a term used to express the different ways, that any particular number of things may be varied, changed, or combined. See COMBINATION.

ALTERNATIVE, in a general sense, implies nearly the same as alternate. See ALTERNATE.

ALTHÆA, marshmallow, in botany, a genus of plants producing a flower with a double empalement; the outer one is monophyllous, irregularly divided at the extremity into nine narrow parts, the interior empalement is also composed of one leaf, cut at the top into five broad segments, and are both permanent, the flower contains five heart-shaped petals, which join together at the base; the filaments are numerous, joined below in a cylindrical form, but loose at the tops, and are inserted in the corollæ; in the center is placed an orbiculated germen, supporting a short cylindrical style, topped with a numerous stigma; the empalement becomes afterward a round depressed capsulæ, divided into several cells, each containing a single compressed kidney-shaped seed.

The common althæa grows in moist places in divers parts of England, the root is perennial, but the stalk is annual, and dies to the ground every autumn; the stalk is upright, with a few small side branches, and furnished with hoary soft angulated leaves; the flower blows in July and August, and comes out from the wings of the leaves shaped like the common mallow, but less, and of a paler colour.

In medicine the leaves of this plant afford a very soft mucilaginous substance in decoction, which is therefore good in all complaints arising from acrimony; thus it is of great service in dysenteries,

The right ascension and declination of the above catalogue is settled to the year 1770.

ANDROMEDA, in botany, a genus of plants, bearing a monopetalous flower, of an oval and

campanulated form, divided into five segments at the brim, which are reflexed: it contains ten tubulated filaments, which are shorter than the corolla; and affixed to it in the center is placed a roundish germen, which becomes a pentagonal capsule, containing five cells, which are filled with many small round seeds: most of the species of this genus are natives of North America; one of which is the chamedaphne of J. Buxbaume.

ANDROSACE, in botany, a genus of umbelliferous plants, whose flowers consist of a five cornered monophyllous cup; the corolla is a monopetalous oval tube, inclosed in the empalement, divided at the brim into five parts, in which is inserted five short filaments, crowned with oblong erect antheræ; the germen is round, supporting a short filiform style, topped with a globose stigma; the calyx afterwards becomes a globose capsule of one cell, opening in five parts, containing several roundish seeds. This genus are all natives of foreign countries.

ANDROSÆMUM, tuffan, in botany, constituting a distinct genus of plants, according to Tournefort; but is comprehended by Linnæus among the hypericums. See the article **HYPERICUM**.

ANDRYALA, in botany, a genus of plants, called by Vaillant eriphorus, and in English downy sow thistle; the cup of the flower is short, hairy, and round, cut in many parts; the flower is composed of many equal hermaphrodite florets, which are monopetalous, and contain five short hairy filaments, topped with cylindrical tubulous antheræ; the ovary, which is situated at the bottom of each floret, supports a filiform style, the length of the filaments, crowned with two reflexed stigma; the ovary becomes afterward an oval seed, topped with down. The species of this genus are natives of France, Spain, and Italy.

ANECDOTE, among historians, implies some fact not formerly published to the world, or very little known.

The word is Greek, ἀνεκδοτὸν, and compounded of ἀν, priv. and εκδοτὸν, published.

ANEMUS, in some chemical authors, implies a wind-furnace used in making strong fires for fluxing metals, &c.

The word is formed from the Greek, ἀνεμῶν, the wind.

ANEMOMETER, an instrument to measure the force or power of the wind, first invented by Wolfius, and mentioned in his Areometer published in the year 1709; and likewise in his Elem. Matheos. as well as in his Mathematical Dictionary. He tells us, the structure is such that it may be preserved even to measure the force of running water, or that of men, horses, &c. when they draw. In the Memoirs of the Academy of Sciences, there is given the description of a new anemometer,

anemometer, which not only expresses on paper the several winds that have blown for twenty-four hours, but also the power and velocity of each. See the articles *WIND* and *VELOCITY*, for the description, construction, &c. of this instrument.

ANEMONIE, the wind-flower, in botany, a genus of polyandrious plants: the flower consists of two or three orders of petals, which are oblong, and disposed in three series over each other; the filaments are capillary and numerous, topped with double upright anthers; the germina are many, and collected in the head of the flower, each crowned with an obtuse stigma. It is destitute both of calyx and pericarpium, but the receptacle is globose or oblong, attenuated and punctuated, and produces numerous and acuminate seeds, inclosed with a down, having the styles affixed to them. There are two sorts of species in this genus, the cultivated and the wild. Those that are raised in gardens, produce a fine variety of beautiful flowers, which blossom in April: the root is tuberous and irregular, of a darkish brown on the outside, whitish within, and hung with many thick fibres, dividing itself in time into numerous heads. The leaves, supported by footstalks, arise from the root, and are divided into a number of segments, and these are again subdivided into others: the flower stalk is round, and tolerably upright; it is not divided or branched, and is bare of leaves except at one place is situated a foliaceous involucre, which is divided at the leaf, and on the summit of the stalk is placed the single flower. These flowers have of late years been cultivated with care, and as they are very beautiful, deserve a place in every curious garden.

The season to plant their roots is in October, observing to cover them in severe weather, and in the succeeding spring they produce their flowers: when the flower and leaves are decayed, the roots should be taken out of the ground, and washed clean, dried, and put in a dry place, till the season of planting. To have new varieties the seeds should be saved, and as their down makes them adhere together, they should be mixed with sand, and well rubbed in the hand, to make them separate and proper for sowing: the time to do which is in the month of August, in light rich earth, observing to shade them from the sun, and properly watered, where they should remain till they blow, which will be in two or three years, when the goodness of them may be judged of, and selected accordingly.

ANEMOSCOPE, an instrument for shewing the velocity of the wind, and also the point of the compass from which it blows, by means of a hand or index to an upright dial, or circular plate, on which the said points are delineated.

The index is turned by a horizontal axis, which axis is turned about by an upright staff, at the top

of which is the vane, and at the lower part is a cog-wheel, which puts the horizontal axis in motion, by means of a trundle-head fixed at its internal extremity. This instrument is extremely simple in its construction, and requires nothing more than that the number of rounds in the trundle-head and cogs or teeth in the wheel be equal. The anemoscope, as described in Plate IV. *fig. 4.* is what was invented by Mr. Pickering, and published in the Philosophical Transactions, N^o 473. The explanation, as given by the inventor, is as follows:

This anemoscope is a machine four feet and a quarter high, consisting of a broad and weighty pedestal, a pillar fastened into it, and an iron-axis, of about half an inch diameter, fastened into the pillar. Upon this axis turns a wooden tube, at the top of which is placed a vane, of the same materials, 21 inches long, consisting of a quadrant, graduated and shod with an iron-rim, notched to each degree; and a counterpoise of wood, as in the figure, on the other. Through the centre of the quadrant runs an iron-pin, upon which are fastened two small round pieces of wood, which serve as moveable radii to describe the degrees upon the quadrant, and as handles to a velum or sail, whose plane is one foot square, made of canvas, stretched upon four battens, and painted. On the upper batten, next to the shod rim of the quadrant, is a small spring, which catches at every notch corresponding to each degree, as the wind shall, by pressing against the sail, raise it up; and prevents the falling back of the sail, upon lessening of the force of the wind. At the bottom of the wooden tube is an iron index, which moves round a circular piece of wood fastened to the top of the pillar on the pedestal, on which are described the thirty-two points of the compass. The figure of this machine may be seen, (Plate IV. *fig. 4.*) where *a* is the pedestal; *b*, the pillar in which the iron axis is fitted; *c*, the circle of wood, on which are described the 32 points of the compass; *d*, the wooden tube upon its axis; *e*, the velum; *f*, the graduated quadrant; *h*, the counterpoise of the vane.

Fig. 5. The velum takes off: *a*, the plane of the velum; *b*, the spring; *c, c*, the wooden radii; *d, d*, the holes through which the pin in the center of the quadrant goes. Its uses are the following:

1. Having a circular motion round the iron axis, and being furnished with a vane at top, and index at the bottom, when once you have fixed the artificial cardinal points, described on the round piece of wood on the pillar, to the same quarters of the heavens, it gives a faithful account of that quarter from which the wind blows.

2. By having a velum or sail elevated by the wind along the arch of the quadrant, to an height proportionable to the power of the column of wind pressing

pressing against it, the relative force of the wind, and its comparative power, at any two times of examination, may accurately be taken.

3. By having a spring fitted to the notches of the iron with which the quadrant is shod, the velum is prevented from returning back upon the fall of the wind; and the machine gives the force to the highest blast since the last time of examination, without the trouble of watching it.

The ingenious contriver of this machine tells us, that he carefully examined what dependence may be had upon it, during the storms of February, 1743-4, and found that it answered exceeding well; for that, in such winds as the sailors call violent storms, the machine had six degrees to spare for a more violent gust, before it comes to a horizontal position.

It is certainly to be depended upon in ordinary weather, the velum being hung so tenderly as to feel the most gentle breeze. There is however reason to fear, that the exposing the anemoscope to all winds for a continuance, must disorder it, especially irregular blasts and squalls. It may not therefore be amiss, in violent weather, for the observer to take the tube with its vane and velum in his hand; in order to know the force of the wind; and, when he has finished his observations, to carry the machine into the house, till the violence of the storm is abated, when it may be replaced in its former situation.

ANETHUM, dill, in botany, an annual umbelliferous plant, with very finely divided leaves, and yellow flowers; producing pale yellowish oval seeds, flattened on one side, marked with three longitudinal striæ on the other, and surrounded about the edges with a leafy margin. It is a native of the warmer climates, cultivated with us in gardens, flowers in July, and in September sheds its seeds, by which the plant is plentifully propagated.

The seeds of dill have a moderately warm pungent taste, and an aromatic smell, but not of the most agreeable kind; they are given as carminatives, to the quantity of a dram at a time, in flatulent colics, and indigestion from a laxity of the organs and visciduity of the humours. The leaves are weaker and less grateful than the seeds; the roots have nothing of their flavour.

Water extracts very little of the virtues of dill seeds by infusion or digestion for some hours. In boiling, their whole flavour exhales along with the watery vapour, and may be collected by distillation: the distilled water, drawn off to the quantity of a gallon from a pound of the seeds, is kept in the shops, and occasionally made the basis of carminative draughts and juleps. Along with the water arises a considerable portion of essential oil, in taste moderately pungent, and smelling strongly of the dill; this is given from one to three

or four drops, or more, as a carminative, and in hiccups.

Rectified spirit, digested on dill seeds, readily extracts both their smell and taste: the colour of the tincture is a bright yellow. The spirit, gently distilled off from the filtered liquor, brings over very little of its flavour, leaving in the extract nearly all the active parts of the dill.

ANEURISM, in surgery, a tumour arising from the dilatation or rupture of the coats of an artery. Aneurisms usually proceed from an artery being accidentally cut or pricked in bleeding, or from preternatural distention, or a corrosion of its coats, &c.

When an artery happens to be cut off by a lancet, the blood gushes out impetuously by starts, and is not easily stopped; an inflammation and change of colour in the part about the vessel succeed, with a tumour and inability to move the arm, if the lancet were used there, from a collection of extravasated blood lodged between the integuments and the interstices of the muscles. If the coats of the artery have been corroded, the symptoms are nearly the same, but come on more slowly, and prove less violent, without any hæmorrhage. The signs of a true aneurism, that is, when the dilatation of the coats of the artery happens, are a pulsation easy to be felt, and sometimes visible to the eye, the tumour generally appearing of the natural colour of the skin. This tumour varies in magnitude, being sometimes as large as an orange, and at others, as big as a child's head; and, when pressed with the finger, generally gives way, but presently restores itself upon removal thereof.

An aneurism happening upon some error in venæsection, is dangerous; but if the blood ceases to flow from the wounded artery, and parts itself between the interstices of the muscles, the surgical operation is necessary; or if that be delayed for a few days, the extirpation of the limb becomes indispensable. It is also dangerous if it proceeds from a corrosion of the coats of the artery; and the more so, when it happens in a part where the operation cannot be performed: but an aneurism from a distention of the canal, without any rupture, is seldom fatal; though reckoned, when large, incurable; the chief inconveniences being the magnitude of the tumour, and pulsation. The diet in all these cases should be slender and balsamic, and the exercise gentle.

ANGARIA, in antiquity, a kind of public service imposed upon the provinces, which consisted in providing horses and carriages for the conveyance of military stores from one place to another.

ANGARIA also signified any kind of oppression or service performed by compulsion.

ANGIOGRAPHY, among anatomists, signifies

sies a description of the several vessels of the human body; as the arteries, veins, lymphatics, nerves, &c.

The word is formed from the Greek, *αγγειον*, a vessel, and *γραφω*, to describe.

ANGEIOTOMY, in surgery, implies the opening a vein or artery, as in bleeding; and consequently includes both arteriotomy and phlebotomy.

The word is formed from the Greek, *αγγελος*, a vessel, and *τινω*, to cut.

ANGEL, a name given to the first and most exalted of all created beings; to those pure, æthereal, intelligent spirits, who are employed by the Almighty to declare his will, or execute his commands, being for this reason called *αγγελος*, (from *αγγελλω*, I send) that is messengers.

Angels have been distributed by ancient writers into three hierarchies, and these divided again into three classes. As thus:

1st Hierarchy.	2d Hierarchy.	3d Hierarchy.
Seraphim,	Dominations,	Principalities,
Cherubim,	Virtues,	Archangels,
Thrones,	Powers,	Angels.

The Seraphim are the most of all other spirits inflamed with holy love: the cherubim are the most enlightened, and communicate their rays and science to the other orders: the Thrones are those that encircle the majesty of God: the Virtues are mighty to work wonders and miracles: the Powers counteract and prevent the malevolence of evil demons: the Dominations have the government of man: the Principalities have the charge of states and kingdoms: Archangels are commissioned only on extraordinary occasions; and Angels are the common heralds and messengers of heaven.

Whatever grounds there may be for this particular arrangement of spiritual beings into so many different classes, allotting to each their peculiar departments, it is not our present purpose to enquire: certain it is that there must be angels, or ministering spirits, since there has been no age or nation so blind or barbarous, as to have doubted of their existence. The Greeks and Romans had their genii or demons, whom the Platonists in particular thought to have part in the government of the world. The Mahometans and Jews have always admitted them; and our Saviour and his Apostles bear testimony to their existence. We find them in the holy scriptures commissioned by the Almighty to correct, improve, exhort; to declare his will, or manifest his anger; to assist the good, to comfort the afflicted, and to appal and punish the evil.

It is generally agreed by divines, that angels are pure and incorporeal substances, created by the great Author of Nature before the world, or at the same period. They are the ministers of hea-

ven, sent down to superintend human affairs: they have the charge not only of kingdoms and provinces, but of particular persons, over whom they are perpetually watching, as so many faithful and affectionate guardians. This is a consideration, which, if duly attended to, would not fail to make us cautious in what manner we conduct ourselves; since there is no action so silent and secret, that is not immediately known to these attendant spirits.

It is impossible for us to know any thing certain of the nature of angels; but we may believe, that though of an order highly superior to that of men, they are not compleat and perfect: for if they had been created thus originally, they could not have sinned; which the holy scriptures inform us some of them did, in rebelling against the Almighty. For this reason, as they are themselves imperfect beings, they cannot properly be the objects of our adoration; which should be paid alone to that ONE SUPREME, who is omnipotent, immortal, infinite, the source and centre of every thing that is great, and good, and perfect.

ANGEL, in commerce, the name of a gold coin formerly current in England. It has its name from the figure of an angel represented upon it, weighed four pennyweights, and was twenty-three and a half carats fine. It had different values in different reigns; but is at present only an imaginary sum, or money of account, implying ten shillings.

ANGELICA, in botany, a large umbelliferous plant, with hollow jointed stalks, and indented oval, pointed leaves, set in pairs along the middle rib, and having an odd one at the end, containing a milky juice, which on drying contracts a yellowish colour; the ribs of the leaves are channelled on the upper side, and joined to the stocks by large membranous bases or sheaths. The seeds are of a pale whitish colour, somewhat oval, flat on one side; and convex, with three longitudinal ridges on the other, surrounded about the edges with a leafy margin. The roots are long and thick, of a dark brown colour on the surface, but the internal white and juicy; and, when dry, of a spongy texture.

There are two species of angelica, the wild and the garden, distinguished by the epithets *silvestris* and *sativa*. The former grows wild, in moist grounds, in several parts of England; is perennial, and flowers in July: the latter is cultivated in gardens. They are similar in quality; but the latter is supposed to be the stronger.

The garden angelica is naturally a biennial plant; but if the stalks are cut down before they run to flower, the roots will send forth new heads, and may by this means be continued for many years. The roots are in their greatest perfection in the second spring: they should be thoroughly dried, kept in a dry place, and frequently aired, otherwise they will grow mouldy, and be eaten by worms.

The roots of angelica are one of the principal aromatics of European growth, though not much regarded in the present practice. They have a fragrant agreeable smell, and a bitterish pungent, mixed with a pleasant sweetish taste. On wounding the fresh roots early in the spring, it yields from the inner part of the bark, an unctuous and odorous juice, of a yellowish colour; and which, being gently exsiccated, retains its fragrancy, and proves an elegant aromatic gummy resin. On cutting the fresh root longitudinally, the yellowish matter, in which the virtue and flavour of the angelica resides, appears concreted into little veins. In this state it readily and totally dissolves by rectified spirit of wine, and tinges the menstruum of a bright golden colour. On distilling off the spirit from this solution, very little of the flavour of the angelica rises with it, nearly all the active matter of the root remaining concentrated in the extract. Water also gains from this root a pretty deep yellow colour, but extracts little of its taste or smell. In distillation with water, there arises a small portion of essential oil, of a highly pungent taste, and smelling strongly of the angelica: the remaining decoction, thus divested of the aromatic matter of the root, is nauseously sweetish and subacid.

The other parts of the plant have the same taste and flavour with the roots; but their active principles are far more perishable. The seeds, which come nearest to the roots, can scarcely be kept till the spring after they have been gathered, without losing their vegetative power, as well as diminishing their medicinal virtues; and, with regard to the leaves, they lose the greater part of their virtues on being barely dried: for some purposes, however, they are well adapted; the fresh leaves, as well as the seeds, being distilled with water, give over to the liquor the whole of their aromatic matter, which in this form proves sufficiently durable. The virtues of the seeds, like that of the roots, is very imperfectly extracted by water, and completely by spirit; and though it rises totally by distillation with water, is left by the spirit almost entire in the inspissated extract. The spirituous tincture is of a bright straw colour; the watery infusion of a dark brown.

The stalks, candied with sugar, make a very agreeable sweetmeat.

ANGELICA, in antiquity, the name of a celebrated dance performed at the pagan feasts of Greece; and so called from the dancers being dressed in the habit of messengers.

ANGELICS, *Angelici*, in ecclesiastical history, an ancient sect of heretics, supposed to have obtained this appellation from their excessive veneration for angels.

ANGELICS is also the name of a congregation of nuns, founded at Milan in 1534, by Louisa Torelli,

countess of Guastalla. They observe the rule of St. Augustine.

ANGELICS is likewise the name of an order of knights instituted in 1197, by Angelus Flavius Comnenus, emperor of Constantinople.

Some will have this order, which still subsists in Italy, to have been much more ancient, and at Constantinople the Great was its founder.

ANGELITES, a sect of heretics, so named from a certain place in Alexandria, called Agellus, or Angellius, where they first of all assembled. They followed the errors of Sabellius.

ANGELOT, the name of a gold coin struck at Paris while subject to the English; and so called from the figure of an angel, supporting the arms of England and France.

ANGER, a violent passion of the mind, consisting in a propensity to take vengeance on the author of some real or supposed injury done the offended party.

ANGERONA, in mythology, the name of a pagan deity whom the Romans prayed to for the cure of a distemper, called the quinzey, in Latin, *angina*; Pliny calls her the goddess of silence and calmness of mind; who banishes all uneasiness and melancholy. She is represented with her mouth covered, to denote patience and refraining from complaints. Her statue was set up, and sacrificed to in the temple of the goddess Voluptas, to shew that a patient enduring of affliction leads to pleasure.

ANGERONALIA, feasts instituted at Rome in honour of the goddess Angerona. They were celebrated on the 21st of December.

ANGINA, in physic, a violent inflammation of the throat, generally called quinzey. See the article QUINZEY.

ANGINA *Liniz*, in botany, a name by which some call the dodder growing on flax, from its choking that plant.

ANGIOSPERMA, in the Linnæan system of botany, implies those plants of the didynamia class, which have their seeds inclosed in a capsule or seed vessel.

ANGLE, in geometry, is the mutual inclination of two lines, or of one line to another, which meet in a point; as the lines BA, CA, (plate VII. fig. 7.) meeting together in the point A. The lines AB and AC are called the legs of the angle, and the point of intersection A, the vertex.

Angles, either denoted by a single letter affixed to the vertex as A, or by three letters, whereof the middle one denotes the angular point, as the angle formed by the lines AB and AC, is sometimes called the angle BAC, or CAB.

ANGLE *acute*, is one which is less than a right angle, or angle of 90°, as the angle DBC (plate VIII. fig. 2.)

ANGLES Adjacent, are such as have their vertexes in one point, being formed by one, two, or more right lines falling on another right line; or, by two or more circles intersecting another circle in the same point. Thus the angles ADC, CDB (plate VII. fig. 6.) are adjacent angles; and in plane geometry, their sum is always equal to two right angles; and therefore, if one of them be acute, the other must be obtuse, and the contrary: whence, also, if one of them be given, the other will be had, it being always the supplement to the other. See **ANGLE Obtuse**.

ANGLES Alternate are those, whether acute or obtuse, formed by a right line intersecting two parallel right lines. So, if AB and CD. (plate VII. fig. 5.) are parallel the one to the other, and GH cuts them in E and F, the angles CEG, BFH, and AFE, DEF, are alternate angles.

The alternate angles are always equal to each other, *per* Simpson's Geom. 8. 1. 1st edit.

ANGLES in Astrology signify certain houses in a figure, or scheme of the heavens, constructed for any given time. Thus the horoscope of the first house is termed, the Angle of the East.

ANGLES of a Battalion, in the military art, are those soldiers who are placed where the ranks and files terminate. See **BATTALION**. The angles of a battalion are said to be blunted, when by any accident, or violent charge of the enemy, those soldiers are broken or killed. It was very common amongst the ancients to remove those parts of the battalion, and by that means form the square battalion into an octagonal one, and charge the enemy in that form; but this is now disused.

ANGLE of a Bastion, in fortification, is the angle ABC, formed by the two faces of the bastion AB and BC (plate X. fig. 4.)

ANGLE at the Center of a Circle, is an angle described in a circle, whose vertex, or angular point, is in the center of that circle.

ANGLE at the Center, in fortification, is the angle BOD (plate X. fig. 4.) formed at the center of the polygon, by lines drawn from thence to the points of the two adjacent bastions.

ANGLES of the Circumference, in fortification, is the angle made by the arc drawn from one gorge to another.

ANGLE, at the Circumference of a Circle, is an angle formed by two chords meeting in the circumference of a circle. Thus AD, DC (plate VIII. fig. 5.) are two chords of the circle ABC, making an angle D at the circumference, and is also called, an angle in a segment.

Per Simp. Geom. 11. 3. 2d edit. all angles at the circumference, standing on the same arc, are equal. Thus the angles ADC, and AGC, are equal to each other; and *per* 10. 3. of the same book, each equal half the angle at the center AEC.

If the arc ABC (fig. 10.) be a semi-circle, then the angle B will be a right angle: if it be greater than a semi-circle, as CDE (fig. 9.) the angle D will be an acute angle; but when less, as EFG, (fig. 8.) it will be an obtuse angle, *per* 11. 3. of Simp. Geom.

ANGLE of Commutation, in astronomy, is the angle comprehended between the true place of the sun, seen from the earth, and that of a planet, reduced to the ecliptic. Thus, let ATBG (plate VIII. fig. 7.) be the orbit of the earth, APG that of any planet, S the sun, and B the planet's place reduced to the ecliptic; then will the angle TSB be the angle of commutation; which is thus found: subtract the planet's heliocentric place from that of the sun, and the remainder shall be the angle of commutation.

Note, As the sine of the angle of commutation is to the sine of the angle of elongation, so is the tangent of the heliocentric latitude of a planet to that of its geocentric.

ANGLE of the Complement of the Line of Defence, in fortification, is an angle made by the intersection of the two complements one with another.

ANGLE of Contact, is the angle ABK, (plate IX. fig. 3.) formed by the tangent AB and curve KB, at the point of contact B. Euclid, prop. 16. b. 3. demonstrates a very remarkable property in the circular angle of contact, viz. That it is less than any assignable right-lined angle; which, notwithstanding it is there demonstrated as clearly as any proposition in the whole book, has given rise to many disputes amongst the mathematicians of almost every age since Euclid. Peletarius, a French mathematician, asserts, that what Euclid calls the angle of contact is no angle at all: in answer to whom, old Clavius says, and perhaps rightly, that angles of contact are true angles; but of a different kind from a right-lined angle: but may be compared to it in the same manner as a line to a surface; and he gives this reason, "Because, if it be ever so often multiplied, it will never be equal to, or exceed a right-lined angle." Tacquet also, and our Dr. Wallis, seem to have fallen into the same error with Peletarius: the latter of which, in his discourse upon this subject, published in his Arithmetic of Infinites, says with Peletarius, that it is no angle; and the former, in a scholium to Prop. 16. l. 3. of his edition of Euclid, denies that any angle whatsoever can be compared to a finite quantity, being, he says, modes of quantities only; from whence it follows that angles cannot be compared to equality and inequality, but to likeness and unlikeness; which, if true, must overthrow every other proposition he has attempted to demonstrate throughout the whole book.

Upon the whole, angles of contact are certainly true angles, and may be compared with one another, though not with right-lined angles, as being infinitely

infinitely smaller. The circular angles of contact ABE, ABG, are to each other in the reciprocal, subduplicate ratio, of the diameters B.D., and B.E.; parabolic ones in the same ratio to their respective parameters; but elliptical and hyperbolic angles of contact are reciprocally in the subduplicate ratio of the ratio compounded of the ratios of their parameters and transverse axes; and Sir Isaac Newton says in his *Principia*, that if the curve HAE, (plate VIII. fig. 1.) be a cubic parabola, the angle of contact BAF will be infinitely greater than the circular one; also, that if there be a series of parabolas of the higher kinds, described to the same axis and vertex, whose abscissas AD, are as the ordinates DE^4 , DF^5 , DE^6 , DF^7 , DE^8 , &c. there will arise a series of angles of contact, every one of which will be infinitely greater than that immediately preceding it. It is to be regretted that this ingenious author proceeded no farther in this affair than he has done, as no doubt his penetrating genius would have discovered, and set this matter in the clearest light; whereas, without a demonstration; it may almost be classed amongst the marvellous. Mr. Stone has attempted to account for it in the following manner. It is known, says he, that if x be put for the abscissa, and supposed infinitely small quantity, that x , x^2 , x^3 , x^4 , &c. and $x^{\frac{1}{2}}$, $x^{\frac{3}{2}}$, $x^{\frac{5}{2}}$, will be each a series of quantities continually decreasing; also, that x , $x^{\frac{1}{2}}$, $x^{\frac{3}{2}}$, $x^{\frac{5}{2}}$, &c. and $x^{\frac{1}{3}}$, $x^{\frac{2}{3}}$, $x^{\frac{4}{3}}$, will be each a series of quantities continually increasing; now as x is supposed infinitely small, every one of these terms must be infinitely greater than that which preceded it; between which progression, and the subject we have been treating of, he apprehends some analogy.

ANGLE of the *Course*, in navigation; see COURSE and RUMB.

ANGLE of the *Counterscarp*, in fortification, is that made by the two sides of the counterscarp meeting before the middle of the curtain.

ANGLE of the *Curtain*; see ANGLE of the flank.

ANGLE, *Curve lined*; see SPHERICAL ANGLE.

ANGLE *Diminished*, in fortification, is that which is made by the meeting of the outermost side of the polygon with the face of the bastion.

ANGLE of the *Ecliptic*; see PARALLACTIC ANGLE.

ANGLE of *Elevation*, in gunnery, is that which the axis of the hollow cylinder, or barrel of the gun, makes with a horizontal line; see ELEVATION.

ANGLE of *Emergence*, is that which any body, &c. projected from one fluid, or medium, into another, makes at its quitting the latter with a perpendicular to its surface. Thus let ab , and cd , (plate IX. fig. 7.) be the parallel surfaces, or boundaries of any medium whatsoever, suppose Bc the direction of any projected body, entering it at c , and going out of it at F, or f , in the direction FD, or fH ; also CF, and fG be perpendicular to ab ,

to cd , then will the angle CFD, or GfH be the angle of emergence.

If the projected body pass through the medium as AEs, the sine of the angle of emergence GfH will not always be equal to that of incidence, but in a constant ratio thereto. But when the direction of the projected body is such, the points of incidence and emergence happen both on the same side of the fluid, or medium, as BcFD, then will the angle of emergence CFD always be equal to the angle of incidence. This is the case if a flat stone be thrown obliquely into the water, which will sometimes dip and emerge several times, according to the velocity with which it is thrown, the figure of the stone, or the obliquity of its incidence.

Sir Isaac Newton, in the XIVth Sect. of the first Chapter of his *Principia*, has given very elegant demonstrations of the two preceding useful propositions, by considering the emerging mediums to consist of particles that uniformly attract the emerged body in its passage through it, and from thence concludes the curve cF to be a parabola; he then shews how the first proposition follows from the nature of that curve; and the second he gathers from a proposition founded upon the first, which is this. The velocity of the body before its incidence is to that after it has emerged, as the sine of the angle of emergence is to that of incidence. From this proposition he also deduces another, which is, that the motion before the emergency must be greater than after it, to cause the body to be reflected.

Hence the proposition on which the whole science of catoptrics is founded, viz. the equality of the angles of incidence and reflection, follows as a corollary, by supposing the depth, or way of emergence, to be infinitely small; or that the body, or ray of light, is reflected from the point of incidence without entering the medium.

ANGLE of the *Epaule*, or *Shoulder*, in fortification, is the angle formed by the flank and the face of the bastion; as the angle BCE (plate X. fig. 4.)

ANGLES *Equal* are such as are measured by the same, or equal arcs of equal circles.

ANGLE of *Evection*. See EVECTION.

ANGLES *External*, are those formed by any side of a right-lined figure, and its adjacent side produced. Thus the angle ABC (plate IX. fig. 9.) formed by the side AB, and its adjacent side DB, produced to C, is an external angle of the trapezium ABDE; per Euclid. B. I. Theo. 2. All the external angles of any right-lined figure taken together are equal to four right-angles; also per Prop. 32. B. I. the external angle in any triangle is equal to both the internal opposite ones.

ANGLE *Flanked*, the same with the angle of the bastion, which see.

ANGLE of the *Flank*, is the angle formed by the flank and the curtain.

ANGLE forming the Flank, is that consisting of one flank, and one demi-gorge.

ANGLE flanking Inward, is the angle made by the flanking line with the curtain.

ANGLE flanking Outward, the same with **ANGLE of the tenaille**, which see.

ANGLES Homologous, in similar figures, are such as retain the same order, reckoning from the first in both figures. Thus in the similar triangles, ABC , and abc , (plate X. fig. 2, and 3.) the angles A and a , B and b , C and c are homologous angles. See **SIMILAR FIGURES**.

ANGLE of Incidence, in optics, is that which is contained between a ray of light incident on any reflecting surface, and a line drawn perpendicular to that surface. Thus the angle ACB , (plate IX. fig. 4.) comprehended between the incident ray AC , and perpendicular CB , is an angle of incidence.

ANGLES Internal, are those made by the inclination of the two adjacent sides of any right-lined figure within it; and their sum, *per* Euclid. B. I. Theo. 1. in every right-lined figure whatsoever, is equal to twice as many right angles, abating four, as the figure hath sides.

ANGLE of Interval between two Places, is that formed by two lines directed from the eye to those places: such is the angle BAC (fig. 10.)

ANGLE of Longitude, in astronomy, is the angle comprehended between the meridian and circle of longitude of the sun, or a star, at the pole of the ecliptic.

ANGLE Lunular, is an angle formed by the intersection of two curves, the one concave, and the other convex.

ANGLE (the Measure of) is the arc of a circle intercepted between the legs of the angle, and whose centre is in the angular point. Thus the measure of the angle BAC is the arc DE (plate VII. fig. 7.) comprehended between the legs AB and BC , and the number of degrees and minutes, &c, contained in that arc, is said to be the measure or quantity of the angle BAC .

Hence it is very easy to measure the quantity of any angle geometrically; for, if you open the sector until the points marked 60 in the line of chords be equal to the radius of the circle, or AE , and then taking the distance DE in your compasses, and try it backward or forward on the sector, till the points of the compass fall both on the same number of degrees and minutes, you will have the true measure of the angle: or, it may be done otherwise, thus; apply the centre of a protractor to the angular point A , in such manner that the leg AC , and radius of the protractor, perfectly coincide; then the degree on the limb of the protractor which is cut by the other leg AB , will shew the quantity of the angle which was required.

ANGLE, mixed Line, is that formed by a right line and a curved one.

ANGLE of the Mote, in fortification, is that which is made before the curtain where it is intersected.

ANGLES Oblique, are all those which are either greater or less than a right angle.

ANGLES Obtuse, are those which are greater than a right angle.

ANGLE of the Polygon, is an angle formed by two lines drawn from the point of one bastion to another; such is the angle LBD (plate X. fig. 4.)

ANGLES Rectilinear, or right-lined, are those whose legs are both right-lined; such is the angle CAB , (plate VII. fig. 7.)

ANGLES Re-entering, in fortification, are those whose angular points turn inwards, and legs open towards the field.

ANGLE of Reflection, is the angle BCD , (plate IX. fig. 4.) comprehended between the line of direction CD , which a body moves in after it has been reflected from the surface of another body $EFGH$, and a line BC , drawn perpendicular to the surface of that body, from the point of contact, C .

ANGLE of Refraction, in dioptrics, is the angle ACB (plate IX. fig. 5.) which a ray of light, CA , after it has been refracted through the medium $DEFG$, makes with the incident ray, OC , produced to B .

ANGLE Refracted, is the angle which a ray of light makes after it has been refracted with a line drawn perpendicular to the surface of the refracted medium. Thus let $DEFG$ (fig. 5.) be the refracting medium contained between the parallel surfaces DE and FG , HC perpendicular thereto, and CA a ray of light after it has been refracted; then will the angle ACB be the refracted angle.

The ratio of the sine of the angle of incidence to that of the refracted angle, hath by numberless experiments been found to be invariable in the same medium; but in different mediums it differs greatly. Sir Isaac Newton, in his Optics, hath shewn that in glass it is nearly as 3 to 2; in rain-water nearly as 4 to 3; and in spirits of wine nearly as 10 to 7: it may likewise here be observed, that when the ray moves out of a rare into a denser medium, the refracted angle is always less than the angle of incidence; and the contrary.

There have been many methods invented whereby the quantity, or law of refraction, may be observed: the following one, as it is not only the most easy, but as it also determines the law of refraction from air into glass, which is what is most wanted, we shall give as an example. Let BEF (plate IX. fig. 11.) be a well polished glass cube, standing on a plain deal board, $abcd$; at the end of which there is another $bche$ fixed at right angles, having the same height with the side of the cube HF , and let their common breadth bc be greater than the side of the cube bH , and

and the length *d* much longer than either; then let those boards with the cube fixed on them close to the perpendicular one *d E H c*, be turned toward the sun at different altitudes, and at every time note the shadow of the top of the perpendicular board, both within the cube at *A*, and without it at *I*; now, since *FA* is the refracted ray, and *FI* the unrefracted one, *HFK* will be the refracted angle, and *HFI* the angle of incidence; and if *FH* be supposed the radius, then will *AH* be the tangent of the refracted angle, and *HI* a tangent to that of incidence; and if *HA* and *HI* be carefully measured on an exact scale of equal parts at every different altitude, you will have their several ratios in numbers, from whence those of their sines may easily be had by trigonometry.

ANGLE Right, is that made by two right lines, or the planes of two circles, drawn or described perpendicular to each other; and its measure is always a quarter of a circle, or 90° .

ANGLE Right-lined, is that whose legs are both right lines, as the angle *CAB* (plate VII. fig. 7.).

ANGLES Salient, in fortification, are such whose angular points turn outward; as the angles of the battions, &c.

ANGLE in a Segment. See **ANGLE at the Circumference**.

ANGLE of a Segment, is the angle which a tangent makes with a chord line, drawn from the point of contact to any other point in the circle's periphery. Thus, let the right line *AC* (plate VIII. fig. 4.) be a tangent to the circle *D B E* in *B*; then if a chord, as *D B*, be drawn from the point of contact, the angles *ABD* and *CBD* are angles of a segment; and the measures of those angles are half the arcs *BD* and *BED* respectively, *ABD* being equal to the angle *BED*, *per* Euclid 32. 3. and so of the other.

Note. The angle *ABD* is called the angle of the lesser segment, and *CBD* that of the greater.

ANGLE of a Semi-circle, is that which the diameter of a circle makes with the circumference. Euclid and several others have given us the following paradox concerning this angle, viz. That it is less than a right angle, and yet greater than any acute right-lined angle whatsoever; the truth is, it is of much the same nature with the angle of contact, and, indeed, of equal use; which is none at all.

ANGLES Similar. See **HOMOLOGOUS ANGLES**.

ANGLE Solid, is the meeting of three or more lines in the same point, but not in the same plane. Thus a solid angle is formed where the two sides and ceiling of a room meet, by the line which is the perpendicular or common section of the walls, and those lines which are the common sections of the two walls and the ceiling: these three lines form a solid angle, consisting of three plane angles; and *per* Euclid, 20. 11. the sum of any two of those angles, howsoever taken, is greater than

the remaining one; and *per* Prop. 21. the sum of the angles, how many soever they be, forming any solid angle, is less than four right angles, or 360° .

A perfect knowledge of the properties of solid angles will be found very useful by those who would form a right understanding of the nature of the five regular bodies.

ANGLE Spherical, is an angle formed on the surface of the sphere by the intersection of two great circles; or, as it is sometimes defined, the mutual inclinations of the planes of two great circles. Thus, let *AD B E* (plate IX. fig. 6.) represent a sphere; on the surface of which, let two arcs of great circles, as *A B*, and *D E*, be described, to intersect one another in *C*; then will *ACD*, *DCB*, *BCE*, and *EDA*, be spherical angles.

All spherical angles are measured on the arc of a great circle, described on the point of intersection *C*, as a pole, at the distance of 90° : and the sum of all the spherical angles which can be formed about a point are equal to four right angles, *per* Emerson's Trigonometry, b. 3. prop. 3.

ANGLE of the Tenaille, in fortification, is the angle made by the intersection of the two lines of defence before the curtain; such is the angle *BID* (plate X. fig. 4.)

ANGLES Vertical, are the opposite angles formed by the intersection of two right lines, or the planes of two great circles. Thus of the former kind are the angles *ADC*, *EDB* (plate VII. fig. 6.) and of the latter, the angles *ACD*, *ECB* (plate IX. fig. 6.) each pair being said to be vertical, with respect to each other.

ANGLE of Vision, or the *optic Angle*, is the angle *BAC*, (plate IX. fig. 10.) formed at the eye by two rays *A B*, *A C*, coming from the extreme points of an object.

ANGLING, the art of fishing with a rod, to which are fitted a line, hook, and bait.

The following rules are necessary to be observed in angling. 1. To place yourself so that your shadow do not at any time fall upon the water, especially if it be shallow. 2. To angle in a pond near the ford where cattle go to drink; and in rivers, in such places as the fish you angle for usually frequent; as, for breams in the deepest water; for eels under banks; for chub in deep-shaded holes; for perch and roach in sewers; for trouts in quick streams.

The best times for angling are from April to October; for in cold stormy weather, or bleak easterly winds, the fish will not bite. The time of the day, in warm months, is in the morning, about nine o'clock, and in the afternoon between three and four. In order to attract fish to the place intended for angling, it will be proper once in four or five days to throw in some corn boiled soft, garbage, worms chopped to pieces, or grains steeped in blood and dried; and, if you fish in a stream, it will be best to throw in the grains above the hook.

The best method of angling with a fly is down the stream; and, in order to make the fish bite freely, be sure to use such baits as you know they are naturally inclined to, and in such a manner as they are accustomed to receive them.

The several methods for angling for salmon, trout, carp, tench, perch, pike, dace, gudgeons, roach, flounders, &c. will be found under the articles *SALMON FISHING*, *TROUT FISHING*, &c.

ANGLO-SAXON, a name given to the language spoken by the English Saxons, in order to distinguish it from the true Saxon, and also from the modern English.

ANGONEÛS, in anatomy, a name given to a muscle of the arm inserted into the ancon, or extremity of the elbow.

ANGUILLA, in natural history, the name by which the writers in that science call the eel. See *EEL*.

ANGUINA, in botany, a name used by different authors for two very distinct genera of plants, called by Linnaeus *trichosanthes* and *calla*. See the articles *TRICHOSANTHES* and *CALLA*.

ANGUINEAL *Hyperbola*. See *HYPERBOLA*.

ANGULAR, in a general sense, signifies something belonging to, or that hath angles. See the article *ANGLE*.

ANGULAR Motion, in astronomy, is the increasing or decreasing angle made by two lines drawn from a central body, as the sun or earth, to the apparent places of two planets in motion. The angular motions of a planet and the sun made in the same time, are reciprocally proportionable to their periodical times.

SECTION.

ANGURIA, the water-melon, in botany, a genus of plants that produce male and female campaniform flowers; the male have three short filaments joined together; the female flowers rest upon an ovary supporting a cylindrical style, the ovary after becomes an oblong fleshy fruit, containing five cells filled with compressed seed. This plant is little raised in England, but cultivated greatly in the warm countries; and the fruit is much esteemed by the inhabitants for their cooling flavour: they are managed here like the musk melon, requiring more room to extend, and in some places produce tolerable fruit.

ANHELATIO, or **ANHELITUS**, among physicians, a shortness of breath, or a difficult and small, but quick, respiration, which happens to sound persons, especially to valetudinarians, after violent exercise.

The word is Latin, and derived from *anheles*, to part, and breathe with difficulty.

ANHIMA, in natural history, the name of a

bird, common in Brazil, resembling a crane in some particulars; but differing from that and all other birds by a slender horn of a bony substance, inserted a little above the origin of its beak: its wings too have each a horn of this kind growing out of the fore-part of the bone. It is larger than a swan, and mottled with black, grey, and white; in some parts are small spots of yellow.

ANHINGA, in natural history, an extremely beautiful water-fowl, found in the Brazils, about the size of our common duck. Its beak is about an inch and an half in length, and has a row of hooked prickles both above and below; its neck is long and slender, and together with its head, of a yellowish colour; the upper part of the back is brown, spotted with yellow; and the breast, belly, and thighs, are of a silvery white.

ANIL, in botany, the Indian name for the indigo plant, called by Linnaeus *indigofera*. See the article *INDIGO*.

ANIMA, the soul, or principle of life in animals. See the article *SOUL*.

ANIMA Mundi, the soul of the universe, is, according to some, a certain, pure, æthereal substance, which, being diffused through the whole mass of matter, informs, actuates, and unites the various parts of it into one great, perfect, organical body. Others define it to be an ignific virtue infused into the chaos, and disseminated through the whole frame for its conservation, nutrition, and vivification.

The moderns reject this notion of an *anima mundi*, as it is absolutely repugnant to experience.

ANIMADVERSION, a term sometimes used to signify correction, sometimes remarks, and sometimes serious consideration.

The word is Latin, *animadverso*, and compounded of *animus*, the mind, and *verso*, to turn.

ANIMAL, in natural history, an organized body, endowed with life and spontaneous motion.

Animals may be considered either as aerial, terrestrial, aquatic, or amphibious. We call those aerial which have wings, with which they can support themselves in the air.

Terrestrial are those whose only place of rest is upon earth. Aquatic are those whose constant abode is upon the water.

Those are called amphibious which live freely in the air, upon the earth, and yet are observed to live long on the water, as if they were natural inhabitants of that element.

Aerial animals may be subdivided into birds and flies. Fishes, which are the chief part of aquatic animals, may be divided into shell-fishes, scaly fishes, and those that have neither apparent scales nor shells.

And terrestrial animals may be divided into quadrupedes, or beasts; reptiles, which have many

many feet; and serpents, which have no feet at all.

Insects, which in their several changes belong to several of the before-mentioned divisions, may be considered together as one great tribe of animals. They are called insects, from a separation in the middle of their bodies, whereby they are as it were cut into two parts, which are joined together by a small ligature, as we see in wasps, common flies, and the like.

Besides all these, there are some animals that are not perfectly of these kinds, but placed as it were in the middle betwixt them, by having something of both; as beasts and birds in them.

The greatest part of animals have five senses, viz. seeing, hearing, smelling, tasting, and feeling. Some reptiles of the earth, and some of the aquatics, want one or more of the senses which are in perfect animals, as worms, oysters, cockles, &c.

One would wonder to hear sceptical men disputing for the reason of animals, and telling us it is only our pride and prejudices that will not allow them the use of that faculty. Reason shews itself in all occurrences of life: whereas the brute makes no discovery of such a talent, but in what immediately regards his own preservation or the continuance of his species. Animals, in their generation, are wiser than the sons of men; but their wisdom is confined to a few particulars, and lies in a very narrow compass. Take a brute out of his instinct, and you find him wholly deprived of understanding.

Animals consist of solids, or firm parts, as flesh, bones, membranes, &c. and fluids, as blood, &c.

The solids are mere earth, bound together by some oily humour; and accordingly are reducible by fire into such earth again.

Thus a bone, being perfectly purged of its moisture by calcination, is found a mere earth, which the least force will crumble into dust, for want of the natural gluten; yet the same bone, by immersing it in water or oil, becomes firm and strong again, and more so in oil than water. And thus cupels will sustain the utmost effects of fire.

The parts of animals are distinguished from those of vegetables by two circumstances: the first, that when burnt they are found perfectly insipid, all animal salts being volatile, and flying off with heat; the contrary of this is found in vegetables, which constantly retain some fixed salt in all their ashes.

The second, that no true acid is contained in any animal juice; nor can any acid salt be extracted from the same; the contrary of which is found in all vegetables.

Yet are animals reconverted into their vegetable nature by putrefaction.

Animals make the subject of that branch of natural history called zoology.

The structure of animals, with their disorders,

remedies, &c. make the subject of anatomy, medicine, &c.

As to the structure of animals, it is observed that the make of every kind of animal is different from every other kind; and yet there is not the least turn in the muscles or twist in the fibres of any one which does not render them more proper for that particular animal's way of life, than any other cast or texture of them would have been.

ANIMAL, used adjectively, signifies something belonging to, or partaking of, the nature of animals.

ANIMAL *Oeconomy*. See OECONOMY.

ANIMAL *Oil*. See the article OIL.

ANIMAL *Secretion*, the separation of the several juices of the body from the blood. See SECRETION.

ANIMAL *Spirits*, a very subtle fluid, supposed to be separated from the brain, and thence diffused into all parts of the body for the performance of all animal and vital functions. See the article SPIRIT.

ANIMALCULE, a minute animal, scarce, if at all, visible to the naked eye.

The word is Latin, *animalculum*, a diminutive of animal.

Animalcules, though so very minute as to be only seen by the assistance of the microscope, are vastly more numerous than any other part of the animal creation. They have been discovered in most liquors, in several of the chalybeate as well as in common water; in oats, barley, wheat, peas, &c. and in the pustules of the itch.

ANIMATED, something inspired with life, or that exhibits marks of being inspired by some spirit or soul.

ANIMATED *Mercury*, a term made use of by Mr. Boyle to denote mercury impregnated with spirituous particles, which when mixed with gold grows hot.

ANIMATED *Needle*, one that is touched with a magnet, or loadstone. See NEEDLE and MAGNET.

ANIMATED *Power*, in mechanics, signifies that the power made use of is a man, horse, or some animal, in opposition to weights, &c.

ANIME, or Gum ANIME, in natural history, is a kind of gum, or rather resin, of a friable substance, inflammable, and soluble in oil. There are two kinds of this gum-resin, distinguished by the epithets of oriental and occidental.

The oriental or Ethiopian anime, is a dry and solid resin, brought to us in large cakes or masses, of an irregular figure, and of a very uncertain colour; some of them are greenish, some reddish, some brown, and some of the colour of myrrh; they all agree in this, however, that they are moderately pellucid, of a tolerable compact texture,

tute, light and easily powdered, of a fragrant smell, very inflammable, and of a resinous and somewhat bitter taste. This, which is the genuine and true anise, is now very rare in the shops.

The occidental anise is a whitish, dry, and solid resin, somewhat resembling frankincense in colour. It is often of a fine yellowish white, between that of frankincense and mastic, and in the purest pieces is very clean and transparent; in general, however, it is much inferior to the oriental in these respects. It is moderately heavy, friable, and somewhat oleaginous to the touch. It is extremely fragrant, especially when burnt, and is of a resinous, acrid, and somewhat bitterish taste. It is brought to us from many parts of America, particularly from New Spain and the Brasilis. The natives call it *joticacia* and *jeticacia*. Our people, from their name of the tree, vulgarly call it resin of courbaril.

ANIME, in heraldry, a term used when the eyes of any rapacious creature are borne of a different tincture from that of the creature itself.

ANINGA, in commerce, the name of a root growing in the Antilles islands, nearly resembling the china root. It is used in the sugar works for refining the sugar.

ANISUM, or **ANISE**, in botany, a small annual umbelliferous herb, which produces flowers and seeds in July. It is cultivated in Germany; but the best feed, which is the smaller sort, comes from Spain. The seeds to be good should be fresh, plump, free from mouldiness, accompanied with a very strong aromatic smell; they are in common use as a warm carminative, and good to expel wind out of the bowels and stomach, and are used by confectioners in sugar-plumbs of various denominations. By distillation an oil may be extracted from aniseeds, which arises with the water in a considerable quantity: this oil is of a yellowish colour, and congeals into a butyraceous white concret; its smell, which exactly resembles that of the seeds, is extremely durable and diffusive, and its taste milder and less pungent than almost any other distilled vegetable oil.

Another sort of anise, called by some botanists *anise stellatum*, is the fruit, or seed-vessel, of a small tree, growing in Tartary, China, and the Philippine Islands, but is little, if at all used in pharmacy. The common anise in the Linnaean system is classed as a species of the *pimpinella*. See **PIMPINELLA**.

ANKER, a liquid measure at Amsterdam, containing about thirty-two gallons English.

ANNALES, a species of history, wherein events are related in the chronological order they happened.

It differs from a perfect history, in being only a meer relation of what passes every year, as a journal is of what passes every day; whereas history

relates not only the transactions themselves, but also the causes, motives, and springs of such actions. *Annales* require brevity only; history demands ornament.

Cicero informs us, that the pontifex maximus, in order to preserve the memory of events, wrote what passed each year on tablets, which were exposed to public inspection in his own house. These tablets were called *annales maximi*; and hence the writers who imitated this simple method of writing were styled *annalists*.

ANNATES, among ecclesiastical writers, implies the first-year's revenue of a spiritual living.

These annates were formerly given to the pope; but at the Reformation they were vested in the king. Queen Anne, however, restored them to the church, by appropriating them to the augmentation of small livings.

ANNEALING, or **NEALING**, an operation performed on glassy earthen-ware, &c. in a particular oven or furnace erected for that purpose. See the article **NEALING**.

ANNEALING OF GLASS, Iron, Steel, &c. See **GLASS, IRON, STEEL, &c.**

ANNE, or *St. ANNE's Day*, a festival observed in the Greek and Latin churches, in honour of Anne or Anna, mother of the Virgin Mary. It is celebrated by the former on the ninth of December, and by the latter on the twenty-sixth of July.

ANNEXATION, in law, implies the uniting lands or rents to the crown.

ANNI Nubiles, in law, signifies the marriageable age of a woman, viz. after she has reached her twelfth year.

ANNIENTED, in law, imports annulled or made void.

ANNIHILATION, the act of reducing any created being to nothing, and stands opposed to creation. The word is formed from the Latin, *ad*, to, and *nihilum*, nothing.

ANNIVERSARY, the annual return of any remarkable day.

The word is formed from the Latin, *annus*, a year, and *verto*, to turn.

Formerly anniversary days particularly denoted those days on which an office was performed for the souls of the deceased, or the martyrdom of the saints was celebrated in the church.

ANNO DOMINI, the year of our Lord, the computation of time from our Saviour's incarnation. See **EPOCHÆ**.

ANNOMINATION, in rhetoric; see **PARONOMASIA**.

ANNONA, in botany, the custard apple, a genus of trees that grows in several places of the West-Indies, whose fruit are in great esteem in those parts, either to please the palate, or by way of medicine: one of the sorts grows in plenty in the

the Bahama islands, which is called by the inhabitants papaw, and will thrive in the open air in England.

ANONIS, rest-harrow, in botany. See O-NONIS.

ANNOTATION, in matters of literature, a brief commentary, or remark on a book or writing, in order to clear up some passage, or draw some conclusion from it.

ANNOTATION, among physicians, implies the beginning of a febrile paroxysm, when the patient begins to shiver, yawn, and stretch.

ANNOTTO, in dying, an elegant red colour, formed from the pellicles of the seeds of a tree common in South-America. It is also called orlean, and roucou.

The manner of making annotto is as follows: The red seeds, cleared from the pods, are steeped in water for seven or eight days or longer, till the liquor begins to ferment; then strongly stirred, stamped with wooden paddles and beaters, to promote the separation of the red skins: this process is repeated several times till the seeds are left white. The liquor, passed through close cane sieves, is pretty thick, of a deep red colour, and a very ill smell: in boiling, it throws up its colouring matter to the surface in form of scum, which is afterwards boiled down by itself to a due consistence, and made up while soft into balls.

The annotto, commonly met with among us, is moderately hard and dry, of a brown colour on the outside, and a dull red within. It is with difficulty acted upon by water, and tinges the liquor only of a pale brownish yellow colour. In rectified spirit of wine, it very readily dissolves, and communicates a high orange or yellowish red. Hence it is used as an ingredient in varnishes, for giving more or less of an orange cast to the sample yellows. Alkaline salts render it perfectly soluble in boiling water, without altering its colour. Wool or silk boiled in the solution, acquires a deep, but not a very durable, orange dye. Its colour is not changed by alum or by acids, any more than by alkalies; but when imbibed in cloth, it is discharged by soap, and destroyed by exposure to the air.

ANNUA *Pensione*, in law, an old writ for granting an annual pension to one of the king's chaplains.

ANNUAL *Motion of the Earth*. See EARTH.

ANNUAL *Equation*, in astronomy. See EQUATION.

ANNUAL *Argument* of longitude. See ARGUMENT.

ANNUAL *Efact*. See EFACT.

ANNUITY, a yearly rent or revenue, paid either for term of life, or of years, or in fee, and for ever.

In common law, the difference between a rent

and an annuity consists in this, that rent is payable out of land; whereas an annuity charges only the person of the grantor; and that, for the recovery of a rent, an action lies: whereas for that of an annuity, there only lies a writ of annuity against the grantor, his heirs and successors. Add, that annuities are never taken for assets, as being no freeholds in law.

For the computation of the value of annuities in arrears on lives, in perpetuity, &c. See INTEREST and PROGRESSION.

ANNULAR, in a general sense, implies something in the form of a ring.

The word is formed from the Latin, *annularis*, and derived from *annulus*, a ring.

ANNULAR, in anatomy, is an epithet applied to several parts of the human body; thus the second cartilage of the larynx is called the annular cartilage; the ligament that encompasses the wrist, and ties the bones together, is termed the annular ligament; and a protuberance of the medulla oblongata is styled the annular process.

ANNULAR is also a peculiar name for the fourth finger.

ANNULETS, in architecture, a small square member in the Doric capital, under the quarter round, sometimes called a fillet, listel, or cincture, rabbit, square, eye-brow, and tinea. It is also a narrow, flat moulding, common to divers places of the columns, as in the base, capitals, &c.

ANNULET, in heraldry, is a mark of distinction proper to the fifth brother of a family.

ANNULLING, a term sometimes used for cancelling, or rendering a deed, sentence, &c. void, and of no effect.

ANNUNCIADA, an order of knighthood in Savoy, originally instituted by Amadeus I. in the year 1409, and called by the founder, the knot of love. The collar consisted of fifteen links interwoven with one another, in the form of a true lover's knot; and the motto F. E. R. T. *fortitudo ejus Rhodum tenuit*. But Amadeus VIII. changed the name to that of Annunciada, and instead of the image of St. Maurice, which was appended to the collar, placed that of the Virgin Mary. At the same time he substituted the words of the angel's salutation, instead of those in the above motto.

ANNUNCIADES, several religious orders instituted in honour of the annunciation.

The first order of this kind was founded by seven merchants at Florence, 1232. The second was a nunnery at Bourges, founded by Joan, queen of France, after her divorce from Lewis XII. The third was a nunnery founded by a Genoese lady in the year 1600. The fourth a friary, founded by cardinal Torrecremata, at Rome.

ANNUNCIATION, a festival celebrated by the church on the twenty-fifth of March, in memory of the annunciation, or tidings, brought by

the angel Gabriel to the Virgin Mary, of the incarnation of Christ.

The feast of this annunciation appears to be of very great antiquity. There is mention made of it in a sermon, which goes under the name of Athanasius. Others carry it up to the time of Gregory Thaumaturgus, because there is a sermon likewise attributed to him upon the same subject. But the best critics reject both these writings as spurious. However, it is certain, this festival was observed before the time of the council of Trullo, in which there is a canon forbidding the celebration of all festivals in Lent, excepting the Lord's-day, and the feast of the annunciation: so that we may date its original from the seventh century.

ANODYNE, among physicians, signifies a medicine that mitigates or removes pain.

The word is compounded of the Greek α , priv., and $\omega\delta\upsilon\nu$, pain.

There are two species of anodynes, distinguished by the epithets proper and improper. The former are such as mitigate the pain by removing the cause. The latter that alleviate it for a time by stupifying the senses. The proper anodynes are called paregorics; and the improper opiates, and narcotics. See the articles PAREGORICS, OPIATES, and NARCOTICS.

ANOMALISTICAL Year, in astronomy, is the time which the earth takes in passing through its orbit, and is mostly called the periodical year; for the space of time belonging to this year is greater than the tropical year, on account of the precession of the equinoxes. See PRECESSION.

ANOMALOUS, in a general sense, is applied to whatever is unequal, irregular, or that deviates from the rule observed by similar things in similar cases.

The word is formed from the Greek, α , priv., and $\omega\nu\alpha\lambda\omicron\varsigma$, equal.

ANOMALOUS Pulse, among physicians, implies a pulse whose strokes are unequal with regard to strength.

ANOMALOUS Verbs, in grammar, are such as are irregularly conjugated, or formed in a manner different from the general rules.

ANOMALY, in grammar, implies an irregularity or a deviation from the common rules.

ANOMALY in astronomy, is an irregularity in the motion of the planets, whereby they deviate from the aphelion or apogee, which irregularity or inequality is called either *mean*, *eccentric*, and *co-equate*, or *true anomaly*.

Eccentric ANOMALY, or *ANOMALY of the Centre*, in the new astronomy, is an arch of an eccentric circle, AEMGP (plate X. fig. 1.) terminated by AP, and by the line DpE drawn through the center of the planet p (which is supposed to be its place in the elliptic orbit A p H P) perpendicular to AP; but in the old astronomy is an arch of

the zodiac, terminated by the lines of the apsidæ, and the line of the mean motion of the center.

Mean ANOMALY, in the new elliptical astronomy, is the area contained under the line Sp, drawn from the sun, which is supposed to be in the focus of the ellipse A p H P to the planet in its orbit at p, and under the line AS and Ap; but in the old astronomy is an arc of the ecliptic, between its mean place and apogee.

True or co-equate ANOMALY, is the distance of the sun from its apogæum, or of a planet from its aphelium; or it is represented by the angle ASp, when the planet comes from A to p, but when the motion of the planet is reckoned from the vernal intersection of the equator and the ecliptic, or from the beginning of Aries, it is called the motion in longitude, which is either a mean motion, such as the planet would have, did it move uniformly in a circle round the sun; or else the true motion where-with the planet describes its orbit, and is reckoned by the arch of the ecliptic it is seen to describe; which true motion is sometimes accelerated and sometimes retarded, according to the distance of the planet from the sun in the various points of its orbit.

Therefore at any given time after the planet has left its aphelion, we find out its place in its orbit by dividing the area of the ellipse A p H P by the line Sp, so that the whole elliptic area may have the same proportion to the area ASp, as the whole periodical time wherein the planet describes its orbit is to the time given: there has been many methods given to divide an ellipse in this manner by Geometricians, which is finding the difference between the true and mean anomaly, or in other words to solve the famous Keplerean problem. Sir Isaac Newton having demonstrated that this problem cannot be solved in finite terms, recourse has therefore been had to approximations: the following method which we presume has the advantage of every other, as well in point of accuracy as expedition, was given by that ingenious astronomer and mathematician Mr. George Witchel, in the Mathematical Magazine, Numb. I.

SOLUTION.

Let the semi-circle AGP be described upon the transverse axis ACP, and through p, the place of the planet, let DpE be drawn, parallel to the semi-conjugate HC, meeting the semi-circle in the point E; join E, S, and the semi-circle will be divided by the line ES, in the same ratio, as the semi-ellipse AHP is by the line pS, as is demonstrated by the writers on conics; let E, C, be joined, upon which, produced if needful, let fall from S, the perpendicular SF; take the arc EM equal in length to the right-line SF, and join M, C: Then it is evident, that the area of the sector ECM, will be equal to the area of the triangle ECS,

Fig. 1. Anomaly.

Fig. 2. Angle.

Fig. 3. Angle.

Fig. 5. Antiparallels.

Fig. 4. Bastion.

Fig. 6. Antiparallels.

Fig. 7. Apotome.

Fig. 8. Apotome.

Fig. 9. Apotome.

ECS; and consequently, the area of the sector ACM, will be equal to the trilinear area ASE: Hence the sector AMC, or the angle ACM, will be proportional to the elliptic area Aps, which is called the mean anomaly of the planet, as the angle ACE, is denominated the excentric anomaly, and the angle Asp, the true, or co-equate anomaly.

In order to find the excentric anomaly, and from thence the true anomaly, let the angle ACM be taken equal to the given mean anomaly; join M, C, and M, S; and upon the right-line MS, let fall from C, the center of the semi-circle, the perpendicular CB, which will, when the excentricity CS is but small in respect to AC, be very nearly equal to the right-line SF, or the arc ME; that is, to the difference between the mean and excentric anomalies: Take the arc Me, equal in length to the right-line CB, join e, C, upon which produced, if necessary, let fall the perpendicular Sf; then if the arc Me be increased, and the right-line Sf diminished in the ratio of eC to Cf, until they become equal to each other, they will then become equal to ME and SF respectively, without sensible error, even in Mercury's orbit; whence the following method of solution is evident.

In the triangle MCS, there is given the two sides MC, the radius of the semi-circle, and CS, the excentricity, with the included angle MCS, the complement of the mean anomaly to two right-angles; whence the angle CMS will become known: Then, in the right angled triangle MCB, there will be given, the angle last found, together with, the side MC, whence, CB also becomes known; but CB, is equal to the arc Me, which measures the angle MCE: This angle being taken from the mean anomaly ACM, leaves the angle ACE, equal to the angle SCF; whence in the right-angled triangle CFS there are known, the side CS, and the angle SCF, by which, Sf and Cf will be found: Then is $Me + eC \times \frac{Sf - Me}{eC + Cf} = ME$ extremely near; but ME is the measure of the angle MCE, which is the difference of the mean and excentric anomalies; and, consequently, the excentric anomaly will become known.

The excentric anomaly being thus found, the true anomaly, or angle Asp, together with the line Sp, or the planets distance from the sun, may be easily obtained by the two analogies given by M. de la Caille, in his Elements of Astronomy; of which, it may not be improper to subjoin the following demonstrations, though somewhat different from his.

ANALOGY I.

As the square-root of the aphelial distance SA, is to the square-root of the perihelial distance SP, so is the tangent of half the excentric anomaly, to the tangent of half the true anomaly.

DEMONSTRATION.

Let the radius of the semi-circle AC = 1, CS = e, and the tangent of half the excentric anomaly = t; then, by trigonometry, we shall have $1 + e : 1 - e :: t :$

$$\frac{1 - e \times t}{1 + e}; \text{ and therefore } \frac{1 + e}{1 - e \times t^2} = \text{the tan-}$$

$$\text{gent of ASE} = \frac{2t}{1 + e - 1 - e \times t^2} : \text{And per conics,}$$

$$GC(1) : HC(\sqrt{1 - e^2}) :: ED : PD ::$$

$$\frac{2t}{1 + e - 1 - e \times t^2} : \frac{2t\sqrt{1 - e^2}}{1 + e - 1 - e \times t^2} = \text{the tangent of}$$

$$ASp = \frac{2\sqrt{1 + e} \times \sqrt{-e \times t}}{1 + e - 1 - e \times t^2} = \frac{2 \times \frac{\sqrt{1 - e \times t}}{\sqrt{1 + e}}}{1 - \frac{e \times t^2}{1 + e}} =$$

$$\text{the tangent of } \frac{1}{2} ASp + \frac{1}{2} ASp; \text{ and, therefore,}$$

$$\frac{\sqrt{1 - e \times t}}{\sqrt{1 + e}} = \text{the tangent of } \frac{1}{2} ASP, \text{ which resolv-}$$

ed into an analogy becomes $\sqrt{1 + e} : \sqrt{1 - e} :: t :$
tangent of $\frac{1}{2} ASP$.

Q. E. D.

ANALOGY II.

As the sine of half the true anomaly, is to the sine of half the excentric anomaly; so is the square-root of the perihelial distance SP, to the square-root of Sp, the distance of the planet from the sun.

DEMONSTRATION.

Let e represent the excentric anomaly, and a the true, the rest of the symbols denoting the same as before; then from what has been proved above, we

$$\text{have the tangent of } \frac{1}{2} a = \frac{\sqrt{1 - e \times t}}{\sqrt{1 + e}}$$

$$\frac{\sin. \frac{1}{2} a \times \sqrt{1 - e}}{\cos. \frac{1}{2} a \times \sqrt{1 + e}} = \frac{\sin. \frac{1}{2} e}{\cos. \frac{1}{2} e}; \text{ whence,}$$

$$\frac{\cos. \frac{1}{2} e \times \sqrt{1 + e}}{\cos. \frac{1}{2} a} = \frac{\sin. \frac{1}{2} e \times \sqrt{1 - e}}{\sin. \frac{1}{2} a}; \text{ and per con-}$$

$$\text{tics, } GC(1) : HC(\sqrt{1 - e^2}) :: ED(\sin. e) :$$

$$pD = \sin. e \times \sqrt{1 - e^2} = \sin. e \times \sqrt{1 + e} \times \sqrt{1 - e};$$

$$\text{but, by trigonometry, we have, } \sin. a : \sin. e \times$$

$$\sqrt{1 + e} \times \sqrt{1 - e} :: 1 : \frac{\sin. e \times \sqrt{1 + e} \times \sqrt{1 - e}}{\sin. a}$$

$$= Sp, \text{ in which expression, instead of } \sin. a \text{ and } \sin.$$

fin. ε , substituting their equals, $2 \times \text{fin. } \frac{1}{2} \varepsilon \times \text{co-f. } \frac{1}{2} \varepsilon$, and $2 \times \text{fin. } \frac{1}{2} \varepsilon \times \text{co-f. } \frac{1}{2} \varepsilon$, we get $S p = \frac{\text{fin. } \frac{1}{2} \varepsilon \times \text{co-f. } \frac{1}{2} \varepsilon \times \sqrt{1+\varepsilon} \times \sqrt{1-\varepsilon}}{\text{fin. } \frac{1}{2} \varepsilon \times \text{co-f. } \frac{1}{2} \varepsilon}$

$$= \frac{\text{fin. } \frac{1}{2} \varepsilon^2 \times 1 - \varepsilon}{\text{fin. } \frac{1}{2} \varepsilon^2} \left(\text{by writing for } \frac{\text{co-f. } \frac{1}{2} \varepsilon \times \sqrt{1+\varepsilon}}{\text{co-f. } \frac{1}{2} \varepsilon} \right)$$

its equal $\frac{\text{fin. } \frac{1}{2} \varepsilon \times \sqrt{1-\varepsilon}}{\text{fin. } \frac{1}{2} \varepsilon}$ and consequently

$$\frac{\text{fin. } \frac{1}{2} \varepsilon \times \sqrt{1-\varepsilon}}{\text{fin. } \frac{1}{2} \varepsilon} = \sqrt{S p}; \text{ therefore fin. } \frac{1}{2} \varepsilon : \text{fin. } \frac{1}{2} \varepsilon :: \sqrt{1-\varepsilon} : \sqrt{S p}.$$

Q. E. D.

I shall now reduce what has been said into the following practical rule, and then proceed to give some examples of its utility.

PRACTICAL RULE.

It will be most convenient to have the eccentricity expressed in decimal parts of the semi-transverse axis: that done, from the log. of the perihelial distance, subtract the log. of the aphelial distance, and let the remainder be called A; likewise to the log. of the eccentricity add the log. 1.758123 (being the log. of the number of degrees contained in an arc equal to the radius) and call the sum B; to the log. A, add the log. tangent of half the mean anomaly, and the sum will be the log. tangent of an arc; subtract this arc from half the mean anomaly, and to the log. sine of the remainder add the log. 1.758123, and the sum will be the log. of the difference of the mean and excentric anomalies, very nearly: then if the mean anomaly be less than 180° , subtract this difference therefrom, otherwise add it thereto, and it will give the first value of the excentric anomaly, which will be sufficiently exact in each of the planets, except Mars and Mercury: in the former the error, when greatest, will be about three-fourths of a second; but in the latter, it will amount to one-third of a minute: in order therefore, to correct it, let the log. sine of the excentric anomaly, as found above, be added to the log. B, and the sum will be the log. of the difference of the two anomalies to a still greater exactness: then, if to the log. co-sine of the excentric anomaly, there be added the log. of the eccentricity, the sum will be the log. of a fraction, which, if the excentric anomaly is more than 270° , or less than 90° , must be added to unity, otherwise subtracted therefrom, and the sum, or difference, will be a number, by which if the difference of the two values of the excentric anomaly be divided, the quotient will be the error of the first value of the excentric anomaly: then if the excentric anomaly is in the first or third quadrant, let the error be subtracted therefrom,

otherwise added thereto, and it will give the excentric anomaly to a very great degree of exactness: lastly, to the log. tangent of half the excentric anomaly add half the log. of A, and the sum is the log. tangent of half the true anomaly.

EXAMPLE I.

In the orbit of Mercury whose excentricity is 0.20589, when the mean distance is unity, it is required to find the excentric anomaly, and from thence the true, together with the distance of the planet from the sun, corresponding to the mean anomaly $130^\circ, 216' 18''$.

From the log. of the perihelial distance	0.79411	-	9.8998807
Subt. the log. of the aphelial distance	1.20589	-	0.0813077
And there remains the log. A.			9.8185730
Half the log. A.	-	-	9.9092865
To the log. of the excentricity	0.20589	-	9.3136353
Add the log. of the radial arc	-	-	1.7581226
And the sum is the log. B.	-	-	1.0717579
These logarithms, when once found, will be constant logarithms in each orbit.			
To the log. A.	-	-	9.8185730
Add the log. tang. of half the mean anom.	65.108090	-	10.3334699
And the sum is the long. tang. of	54.83575	-	10.1520429
The log. sine of the difference	10.277515	is	9.2514339
The log. of the radial arc, add	-	-	1.7581226
The log. of -	10.222486	-	1.0095565
Which, because the mean anom. $130^\circ, 216' 18''$ is less than 180° , is to be subtracted therefrom.			
Difference, or first value of the excentric anomaly	119.993695		
The log. sine of which is	-	-	9.9375582
The log. B, add	-	-	1.0717579
The log. of -	10.216830	-	1.0093161
Mean anomaly	130.216181		
Difference, or second value of the excentric anom.	119.999351		
The log. co-sine of the first value of the excentric anomaly	119.913695	is	9.6988872

Th:

The log. of the ex- } 0,20589 add 9.3136353
centricity
The log. of the } 0,102925 - 9.0125225
fraction

Which, because the excentric anomaly is more than 90° and less than 270°, must be subtracted from unity, and there remains 0,897075; the log. of which is } 9.9528288
Which taken from the log. of 0,005656 the difference of the two values of the excentric anomaly, which is } 7.7525094

There remains the log. of the error 0,006305 } 7.7996806

Which according to the rule being added to the first value of the excentric anomaly, will give the true value thereof, viz. 120°,000000.

Then to the log. tang. of half the excentric anomaly } 60,000000 - 10.2385606

Adding half the log. of A } - - - - 9.9092865

We have the log. tang. of half the true anomaly } 54,5695202 - 10.1478471

Therefore the true anomaly is } 109,1390404 = 109°8'20",55

To the log. sine of half the excentric anomaly } 60,0000 - - - 9.937530

Add the log. of the square-root of the perihelion distance } - - - - 9.949940

And from the sum of the logarithms } - - - - 9.887470

Subtract the log. sine of half the true anomaly } 54,5695 - - - 9.911061

And there remains the logarithm } - - - - 9.976409

Which multiplied by 2, gives the log. of the true distance of Mercury from the sun } 0,89705 - - - 9.952818

In the preceding example the error is a maximum in this orbit, and amounts to no more than $\frac{1}{1778}$ part of a second; but as there is no necessity for this great accuracy, we may abridge the operation in some measure, and yet obtain the conclusion sufficiently exact for real use: thus, if we proceeded no farther than the second value of the excentric anomaly, in this example we should not err above two seconds; but if this be thought too much, let the difference of the two values of the excentric anomaly 0,0057, taken only to four

places of decimals, be divided by 0,9, instead of 0,897075, and the error will be but $\frac{1}{10}$ of a second.

EXAMPLE II.

Let the excentric anomaly of Mars be required, when the mean anomaly is 64°,59175.

In this orbit the excentricity is 0,09254, and the log. thereof 8.996323; the log. A is 9.919391, and the log. B. 0.724446: Then

To the log. A } - - - - 9.919391
Add the log. tang. of half the mean anomaly } 32,2959 - - - 9.800767

And the sum is the log. tang. of } 27,6994 - - - 9.720158

Difference } - - - - 4.5965 sine 8.903833

Log. of the radical arc, add } - - - - 1.758123

The sum is the log. of } 4,5916 - - - 0.661961

Which, according to the rule, must be subtracted from the mean anomaly } 64,5917 $\frac{1}{2}$

And there remains the first value of the excent. anom. } 60,0001 $\frac{1}{2}$; which differs from the truth only by 0,0001 $\frac{1}{2}$, or half a second; but if the second value thereof be found, the error will become too inconsiderable to be regarded. As all the other planets have their excentricities much smaller, the first value of the excentric anomaly, in each of them, will be sufficiently exact, without further trouble.

I shall now conclude with the following Table, which exhibits all the constant logarithms for each of the planetary orbits:

Planets.	Excentricities, the mean dist. being unity	Logarithms of the excentricities	The logarithm A	The logarithm B.	Log. of the square-root of the perihelion dist.
Saturn	0,05700	8.755875	9.950434	0.514011	9.987256
Jupiter	0,04811	8.683157	9.958085	0.441280	9.989271
Mars	0,09254	8.966323	9.919391	0.724446	9.978914
Earth	0,01681	8.225568	9.985398	0.683691	9.996319
Venus	0,00698	7.843953	9.991936	0.602076	9.998479
Mercur.	0,20589	9.315635	9.818573	1.071758	9.949940
Moon	0,05505	8.740757	9.952136	0.498880	9.987704

ANOMOEANS, in ecclesiastical history, the name by which the pure Arians were distinguished in the fourth century, in contradistinction to the Semi-Arians.

The word is formed from the Greek, *ἀνομοῖος*, different, dissimilar: for the pure Arians asserted, that the son was of a nature different from, and in nothing like, that of the father: whereas the Semi-Arians acknowledged a likeness of nature

in the son; at the same time that they denied, with the pure Arians, the consubstantiality of the word.

The Semi-Arians condemned the Anomœans in the council of Seleucia, and the Anomœans in their turn condemned the Semi-Arians in the councils of Constantinople and Antioch, erasing the word *ἐκείνους*, like, out of the Formula of Rimini, and that of Constantinople.

ANONYMOUS, something without a name.

The word is Greek, *ἀνώνυμος*, and compounded of *α*, priv. and *ὄνομα*, a name.

It is generally applied to such books as are published without the name of the author; and to such authors whose names are unknown.

ANOREXY, among physicians, implies a want of appetite, or a loathing of food.

The word is Greek, *ἀνορέξια*, and compounded of *α*, priv. and *ορεγμαι*, to covet or desire.

The anorexy is either an essential disease, proceeding from a fault in the stomach, or derived from other disorders. When it is an original disease, it generally proceeds from voraciousness, and a hard diet; whence crude and undigested humours will arise and prevent digestion; which is often known from a sense of weight in the stomach, or from copious wind and eructations of various kinds, chiefly the nidorous and acid; or from a nausea and reaching to vomit. In old persons, when the whole body is feeble, it may proceed from want of spirits, or the fluids being defective, or from a debility of the contractive force and motions of the stomach, whence an universal decay proceeds.

This disorder is often a symptom of other diseases, particularly the acute, as inflammations, asthma, dropsy, hypochondriac passion, melancholy, the gout, vomiting, or dysentery; or when the humours are so corrupt, and the spirits so oppressed in malignant diseases, that the faculty of digestion is depraved, or nature may be so busied in expelling another disease, as to neglect this. In the last case it cannot be cured till the disease itself is vanquished.

In the spontaneous anorexy, when the stomach is loaded with crudities, which cause a reaching to vomit, a single emetic will often perform a cure, joined to a stomachic remedy: but if there is no reaching, the humours are to be incised and digested with bitter salts, such as the salts of bitter herbs, tartar vitriolated, *arcenum duplicatum*, or the like, given in powder from a scruple to half a dram, several times in a day; or terra foliata tartari dissolved, to sixty drops or more. After this the cathartic, composed of bitter ingredients, or Epsom salt, may be given.

When the stomach and intestines are purged, bitter elixirs and tinctures should be used, combined with aromatics, from fifty to sixty drops, or

upwards, to restore the tone of the stomach. Candied ginger, orange-peel, or elixir vitrioli, especially when the peccant humour is alkalious or bilious, may be properly added to the infusions of bitter-roots and herbs, with aromatics in wine, especially wormwood wine, and the like stomachic liquors.

When the crudities of the stomach are acid, absorbents are proper, such as crabs eyes, mother of pearl and coral, and then a suitable purge of aloetic pills or rhubarb, or a bitter cathartic salt. Magnesia alba is likewise useful on this account, being absorbent and useful in the hypochondriac passion. This should be taken for some days, from fifteen to twenty grains; if the dose be enlarged to a dram or two, it will purge pretty briskly. The crudities being evacuated, bitters and aromatics are proper, as well as chalybeates and tinctures of steel; spa waters, and other mineral waters of the same kind, together with exercise, and now then a draught of generous wine will be found very advantageous. Smoking tobacco frequently is hurtful, as well as drinking of drams; the diet should be regular, and the patient must avoid aliments that are hard of digestion, fat, or flatulent, and also intense studies.

ANSÆ, in astronomy, are two parts of Saturn's ring, which appear on each side that planet, when viewed through a telescope. These ansæ, or handles, sometimes appear open, and sometimes not; the reason of which see under the article SATURN.

ANSER, the goose, in natural history; see the article GOOSE.

ANSER, in astronomy, a small star of the fifth magnitude in the milky-way, between the eagle and swan. For its right ascension, declination, &c. see the constellation VULPECULA.

ANSES, in astronomy, the same with ansæ. See ANSÆ.

ANT, *Formica*, in natural history, the name of a well-known insect, celebrated both for its industry and œconomy.

The sight of ants is really very instructive. They are a little people united, like the bees, in a republic governed by its own laws and politics. They have a kind of oblong city, divided into various streets, that terminate at different magazines. Some of the ants consolidate the earth, and prevent its falling in, by a surface of glue with which they incrust it. Those which we commonly see, amass several splinters of wood, which they draw over the tops of their streets, and use them as rafters to sustain the roof; and across these they lay another rank of splinters, and cover them with a heap of dry rushes, grass, and straw, which they raise with a double slope, to turn the current of the water from their magazines; some of which are appropriated to receive their provisions, and in

the

the others they deposit their eggs, and the worms that proceed from them.

As to their provisions, they take up with every thing eatable, and are indefatigable in bringing home their supplies. You may see one loaded with the kernel of some fruit, another bends under the weight of a dead gnat. Sometimes several of them are at work on the carcase of a May-fly, or some other insect. What cannot be removed they eat on the spot, and carry home all that is capable of being preserved. The whole society is not permitted to make excursions at random: some are detached as scouts, to get intelligence; and, according to the tidings they bring, all the community are upon the march, either to attack a ripe pear, a cake of sugar, or a jar of sweet meats; and, in order to come to this jar, they leave the garden, and ascend the house; there they find this mine of sugar, this rich Peru of sweets, that opens all its treasures to their view. But their march to it, as well as their return from it, is under some regulation: the whole band is ordered to assemble and move in the same track; but the injunction is not executed with much severity, and they have liberty to expatiate when they have an opportunity to spring any game in the country. The green vermin that make an infinite waste among flowers, and cockle the leaves of the peach and pear trees, are surrounded with a glue, or kind of honey, which is sought for by the ants with great avidity; but they are not solicitous either for the flesh of these creatures, or for any part of the plant. These are the vermin who are the authors of all that destruction to our trees, which is falsely imputed to the ants, and draws upon them a very unjust and cruel persecution.

The ants, after they have passed the summer in a constant employment and fatigue, shut themselves up in the winter, and enjoy the fruits of their labour in peace; however, it is probable, they eat but little in that season, and are either benumbed, or buried in sleep, like a multitude of other insects; and therefore their industry in storing up provisions is not so much intended to guard against the winter, as to provide, during the harvest, a necessary sustenance for their young. They nourish them, as soon as they leave the egg, with an assiduity that employs the whole nation; and the care of their little progeny is esteemed a matter of importance to all the state.

When the young quit the egg, they are little worms, no longer than common grains of sand, and after they have for some time received their aliment, which is brought to them in common, and distributed in equal proportions, they spin a thread, and wrap themselves up in a white web, and sometimes in one that is yellow; at which period they cease to eat, and become aurelias. In this state, some people fancy they are the eggs of

ants, when in reality they are the nymphs, out of whole ruins the new pismires are to rise. Though the young discontinue their eating, their nurture still proves very fatiguing to their parents. These have generally several apartments, and remove their young from the nursery to some other mansion they intend to people. They either raise the aurelias toward the surface of the earth, or sink them to a distance from it, in proportion as the season is either warm or cold, rainy or dry. They raise them when the weather proves serene, or when a long drought is succeeded by gentle dews; but, at the approach of night and cold, or the appearance of showers, they clasp their beloved charge in their arms, and descend with them to such a depth, that one must then dig above a foot into the earth before those aurelias can be discovered.

If a mouse, frog, or other like animal, be placed in an ant-hill, he will be devoured, in a few days, to the bones and ligaments. Hence we are furnished with a method of obtaining skeletons of those animals, exquisitely beautiful and perfect, far surpassing any thing that can be executed by artificial anatomy. The subject is for this purpose to be inclosed in a wooden box, and properly distended, to prevent the parts from collapsing or being crushed together by the earth. The box is to be perforated with a number of holes, through which the insects will presently find their way.

ANT-EATER, in natural history, the name of an American quadruped that lives upon ants.

This creature is as long and as tall as a middle-sized dog; his hind legs resemble those of the bear; but his fore legs are more slender. His fore feet are flat, and divided into four toes, armed with long claws; but those behind have five toes. His head is long, with a sharp prominent snout, small round black eyes, and very black ears. Those that have measured the tongue, affirm, that they have found it upwards of two feet in length, but very slender: he is obliged to bend part of it back when he keeps it within his mouth, the jaws being too short to contain it without this artifice.

He lives upon ants, as was observed above, and when he has found out one of their nests, he opens the upper part of it with his claws, that he may have room to put in his snout and tongue. This is besmeared with a slimy liquor, and is soon covered with ants, when he draws it into his mouth and swallows them. He repeats this practice as long as they will run into the same snare.

The tail of this creature is very remarkable, and in some measure resembles that of the fox. It is generally two feet in length, almost flat, and covered on all sides with hair, from fifteen to twenty inches long: it is a little harsh, which gives it somewhat the appearance of a horse's tail; is very strong, and he can move it just as he pleases; when he turns it upon his back, it entirely covers it.

it, and defends the creature from the rain, which he greatly dislikes.

ANT-BEAR, the same with ant-eater described in the preceding article.

ANT-HILLS, in husbandry, are little hillocks of earth which the ants throw up for their habitation for the breeding their young. They are a very great mischief to dry pastures, not only by waiting so much land as they cover, but by hindering the scythe in mowing the grass, and yielding a poor hungry food pernicious to cattle.

The manner of destroying them is to cut them into four parts from the top, and then dig into them so deep as to take out the core below, so that, when the turf is laid down again, it may lie somewhat lower than the level of the rest of the land; and this will prevent ants from returning to the same place, which otherwise they would certainly do. The earth that is taken out must be scattered to as great a distance as may be, otherwise they will collect it together and make another hill just by.

The proper time for doing this is winter, and, if the places be left open, the frost and rains of that time of the year will destroy the rest; but in this case care must be taken that the holes are covered up early enough in the spring, otherwise they will be less fertile in grass than the other places.

In Hertfordshire they use a particular kind of spade for this purpose. It is very sharp, and formed at the top into the shape of a crescent; so that the whole edge makes up more than three fourths of a circle: this cuts in every part, and does the business very quickly and effectually: others use the same instruments that they do for mole-hills.

Human dung is a better remedy than all these, as is proved by experiment; for it will kill great numbers of them, and drive all the rest away, if only a small quantity of it be put into their hills.

ANTA, in ancient architecture, a square pilaster, placed at the corners of the buildings. Le Clerc uses the term to signify a kind of shaft of a pillar, without base or capital, and even without any moulding.

ANTAGONIST Muscles, in anatomy, are those which have opposite functions, as flexors and extensors; abductors and adductors, &c.

ANTARCTIC, or **ANTARTIC**, in a general sense, denotes something contrary or opposite to the northern or arctic pole; thus the antarctic pole is the southern end of the earth's axis; and the antarctic circle is one of the lesser circles of the sphere, parallel to the equator, and distant $23^{\circ} 30'$ from the south pole: it is likewise one of those circles which in geography and astronomy are called the polar circles.

ANTARES, in astronomy, a bright star of the first magnitude in scorpio. This star is proper to

be observed with the moon, when she has southern declination, for determining the longitude, as well as settling the moon's place, &c. See the constellation **SCORPIO**.

ANTE, in heraldry, implies the pieces being let into one another, in the form expressed in blazoning; as by dove-tails, rounds, swallow-tails, or the like.

ANTECEDENT, in a general sense, implies something that goes before another, either with regard to time or place.

The word is Latin, *antecedens*, and compounded of *ante*, before, and *cedo*, to go.

ANTECEDENT, in grammar, is the word to which the relative refers. Thus in the sentence, "The book that we read," the word book is the antecedent.

ANTECEDENT, in logic, is the first proposition of an enthymema. See the article **ENTHYMEMA**.

ANTECEDENT, in mathematics, is the first term in any ratio, or proportion, when the terms are compared together. Thus, in the ratio of 7 to 8, or of x to y , 7 and x , are the antecedents, and 8 and y , the consequents.

ANTECEDENT Decree, in the school philosophy, is a decree preceding some other decree. It is a famous dispute whether predestination be a decree antecedent, or subsequent to faith.

ANTECEDENT Signs, among physicians, such as are observed before a distemper is formed sufficiently to be reduced to any particular class. Thus a bad disposition of the blood is an antecedent sign, because it precedes an infinite number of diseases.

ANTECEDENTIA, in astronomy, an apparent motion of a comet, planet, or other point in the heaven toward the west, or contrary to the order of the signs.

ANTECHAMBER, in architecture, implies the chamber that leads to the chief apartment.

The word is compounded of the Latin preposition, *ante*, before, and *chamber*.

ANTEDATE, in law, implies a spurious or false date, prior to the true date of any writing.

The word is compounded of the Latin, *ante*, before, and *datum*, a date.

ANTEDILUVIAN, signifies in its general sense, something that existed before the deluge. It is a Latin word, compounded of *ante*, before, and *diluvium*, a deluge.

ANTEDILUVIAN Philosophy, means that philosophy which was known and practised by the patriarchs before the flood. This in all probability was very confined and imperfect; as it is observable that in all countries, where the arts and sciences have flourished, they have advanced by a regular progression to maturity. Indeed it is in these, as in the body natural; which by a daily, yet imperceptible encrease, goes on from infancy to youth,

youth, and from youth to manhood; 'till at length it arrives at its full strength and vigour.

ANTEILUVIAN *World*, the earth with its inhabitants, as they existed before the deluge. Dr. Burnet in his *Philosophical Romance*, which he calls a Theory of the Earth, supposes, that before the flood there was no sea, no mountains, no rocks, or broken caves, but all was one continued and regular mass, smooth, simple, and compleat. He carries us back, to prove this hypothesis, to the original chaos; in which were mingled together air, water, and earth, without any order of higher or lower, heavier or lighter, solid or volatile.

When the earth first arose out of this chaos, he says the heavier and grosser parts sunk down to the middle, (for there he supposes the centre of gravity) and the lighter swam above: this lighter fluid part was impregnated with oily and bituminous substances, as well as the finer and more subtle parts of the earth, which concentered, and formed a crust upon the water. This crust was the antediluvian earth; in praise of which the very ingenious doctor expatiates largely, as the fittest soil that could possibly have been invented, to produce every thing necessary for the support of its inhabitants. "In this smooth earth, says he, "were the first scenes of the world; and the first generations of mankind; it had the beauty of youth and blooming nature, fresh and fruitful, and not a wrinkle, scar, or fracture, in all its body; no rocks nor mountains, no hollow caves nor gaping channels, but even and uniform all over. And the smoothness of the earth made the heavens so too; the air was calm and serene; none of those tumultuary motions and conflicts of vapours, which the mountains and winds cause in ours: it was suited to a golden age, and to the first innocence of nature."

What a deplorable thing was the transgression of Adam, and the licentiousness of his descendants, that they should deprive us of so charming a world, as is here described? and how little providence must there have been in the wise Author of nature, to create so beautiful a frame as this, which in so short a space as about sixteen hundred years, was to be changed into its present form? a form that is all over rugged and uneven; with crows and uncouth desarts, rough and craggy mountains, wild and tempestuous oceans, hollow grotts, and dreary caverns, with a thousand other dismal appearances, the very idea of which would have frightened poor Adam out of his senses. What shall we say now, if notwithstanding what Dr. Burnet has told us, the world was fashioned by the divine Architect, pretty nearly as we see it at present? Dr. Woodward is clearly of this opinion, that the face of the terraqueous globe, before the deluge, was the same as it is now, viz. unequal, distinguished into rocks and plains, dales and mountains; that there were

springs and rivers; that the sea was then salt, as it is at present, and subject to winds and tides; that there was the same succession of weather, and the same vicissitudes of seasons.

Mr. Whiston imagines that the chaos, out of which this earth of ours was formed, had been the atmosphere of a comet; that the annual motion of the earth began as soon as it assumed a new form, but that the diurnal motion did not take place till after the fall of Adam; that before the deluge the year began at the autumnal equinox, which is not improbable, as the Jews began their year at that period, before they returned from their captivity in Egypt; that the orbit of the earth was a perfect circle, and that the solar and lunar years were the same, each consisting of just three hundred and sixty days.

ANTELOPE, in natural history, the name of an animal called, by Latin authors, *gazella Asri-cana*, and thought by some to be the same as the Lybian goat.

The antelope is very swift; has a white belly, and the rest of the body of a fallow colour; the white and the fallow on the sides are parted by a black stripe; the eyes are black, the ears large, the tail blackish, and a stripe a little more brown than the rest of the hair descends from the eye down to the muzzle. He is about the size of a roe-buck, and his hair very short. The eyes are black and large; and the horns are likewise black striped crossways. They are about fifteen inches long, and near an inch in diameter at the bottom.

ANTENNE, in natural history, slender bodies, with which nature hath furnished the heads of insects, being the same with what are called in English the horns or feelers.

ANTEPENULTIMA, in grammar, the third syllable from the end of any word, or the last syllable but two.

ANTEPREDICAMENTS, in logic, certain preliminary questions tending to illustrate the doctrine of predicaments and categories. See PREDICAMENTS.

ANTEVIRGILIAN *Husbandry*. See HUSBANDRY.

ANTHELIX, in anatomy, the inward protuberance of the external ear. See EAR.

ANTHELMINTICS, among physicians, medicines proper to destroy worms. See WORMS.

ANTHEM, a church song, consisting of some passages of Scripture set to music, and adapted to some solemnity.

ANTHEMIS, in botany, a name given by Linnaeus for the chamæmelum of Tournefort. See CHAMOMILE.

ANTHERÆ, among botanists, are the small buttons or summits, which grow on the tops of the filaments or stamina of flowers, and contain a

prolific powder, analogous to the male sperm of animals.

ANTHERICUM, in botany, a name given by Linnaeus to the phlangium and asphodel of other botanists. See the article SPIDERWORT.

ANTHOLOGY, a discourse or treatise on flowers.

The word is compounded of the Greek, *ανθος*, a flower, and *λογος*, a discourse.

ANTHOLOGY is also a name given to a collection of Greek epigrams.

ANTHONY, or *Knights of St. ANTHONY*, a military order instituted by Albert, duke of Bavaria, Holland, and Zealand, when he meditated a war against the Turks in 1382. The knights wore a collar of gold, made in the form of a hermit's girdle, from which hung a stick, cut in the form of a crutch; as represented in the pictures of St. Anthony.

St. ANTHONY's Fire, a name sometimes given to the erysipelas. See ERYSIPELAS.

ANTHOCEROS, in botany, a genus of mosses which are destitute of flower, petals, and stamina instead of which there is a single, very long, and subulated anthera, arising from the base of the calyx: the female flower, which is monophyllous, and divided into six parts, is often found on the same plant with the male, and sometimes on a different plant; it commonly contains three roundish seeds, which are naked, and lodged in the bottom of the calyx.

ANTHOLYZA, in botany, a genus of plants in the Linnæan system, producing lilaceous flowers; the roots are bulbous and round, from which arise several deeply furrowed leaves about a foot long; between these arise the flower stem, which hath several flowers, consisting of one leaf divided into six unequal parts at top; one of these segments is stretched far beyond the other, and is erect; the margins are waved and closed together, enveloping three filaments crowned with pointed anthers; beneath the flower is placed the germen, supporting a single style, which is topped with a trifid reflexed stigma; the germen afterward turns to a three-cornered capsule of three valves, containing several triangular seeds. This genus is comprehended among the gladiolus by other botanists.

ANTHORA, in botany, an appellation given to several species of the aconite, called by some helmet-flower, and anthora, supposed to be the zedary of the Arabians. The anthora radix of the shops is the root of the aconitum saluteriferum of C. Bauhine, and is what the official prescriptions intend, whenever this is ordered. It grows in the mountains of Switzerland and Savoy, and is of a warm bitterish taste, and reckoned a cardiac and alexipharmic: it is esteemed good in malignant fevers; and is prescribed as an antidote against

poisons, particularly to obviate the bad effects of the poisonous aconite. It is much of the same nature as the contrayerva root, on which account it is called by some the German contrayerva.

ANTHOS, in botany, a name given by some writers to the rosemary. See the article ROSEMARY.

ANTHRAX, a name by which the ancients called a gem known at present by the name of carbuncle. See CARBUNCLE.

ANTHROPOGRAPHY, the description of the human body, its parts, structure, &c.

The word is formed from the Greek, *ανθρωπος*, a man, and *γραφειν*, to describe.

ANTHROPOMORPHITES, was the name given to a sect of heretics, who through ignorance and simplicity took every thing that was spoken of God in Scripture in a literal sense, as that Adam heard the voice of God walking in the garden; from which they concluded that the Almighty had the shape of a man, with real hands and feet; and the same organization of members that we have. And when it is said, *That God created man in his own image*, they supposed this to mean as to his outward form, as well as his soul; which was thought by them to be corporeal, and to have a real and visible shape and figure.

The word is derived from the Greek, *ανθρωπος*, a man, and *μορφη*, the form or figure. They were also called Audiens.

ANTHROPOPHAGY, the act of eating human flesh.

The word is formed from the Greek, *ανθρωπος*, a man, and *φαγειν*, to eat.

ANTHOSPERMUM, in botany, the amber-tree, so called from the leaves when bruised emitting a fragrant scent: it is a polygamious plant, producing male, female, and hermaphrodite flowers; the male flowers are apetalous, but its calyx supports four upright capillary filaments; the female flowers are the same as the male, but instead of stamina there is an ovary supporting two recurved styles, which becomes a roundish capsule, containing several angular seeds; the androgynous flower partakes of the male and female, having two pistils and four filaments, with the germen below. This plant has been called by some, *frutex Africanus ambram spirans*, or, The African shrub smelling like amber.

ANTHYPOPHORA, in rhetoric, the same with hypophora. See HYPOPHORA.

ANTICARDIUM, in botany; see the article SCROBICULUM.

ANTICHRIST, in scripture, implies one who will oppose the religion of Jesus Christ, and will appear upon the earth as the great enemy of Christianity, some time before the end of the world. This is he whom St. Paul, in his second epistle to the Thessalonians, speaks of as "the man of

"sin, the son of perdition, who opposeth and exalteth himself above all that is called God, or that is worshipped; so that he, as God, sitteth in the temple of God, shewing himself that he is God." The coming of Antichrist will be preceded by many signs in heaven, and upon the earth: "The sun shall be darkened, and the moon shall not give her light, and the stars shall fall from heaven, and the powers of heaven shall be shaken." His reign however will be short, and for this reason, because otherwise "no flesh would be saved," since he will "deceive if it is possible even the elect." Some are of opinion that it will last three years and a half, according to these words of Daniel, "and it shall be for a time, times, and an half." This they pretend is confirmed by several other passages of Scripture, particularly in the Revelations, where it is said, "the holy city shall be trodden under foot forty and two months." Enoch and Elias will be sent by God to assist and encourage the faithful for twelve hundred and sixty days, and to fight with Antichrist, who shall overcome and slay them; but after three days and a half the Spirit of Life from God shall enter into them, and they shall be revived.

Some furious Protestants have endeavoured to prove, with far more zeal than charity, that this prophecy has been already fulfilled, and that Antichrist is neither more nor less than the Pope of Rome.

ANTICOR, in farriery, implies an inflammation of a horse's throat, being the same with the quincy in the human species.

ANTIDOTE, among physicians, implies a remedy against pestilential diseases.

It also signifies a medicine which prevents the ill effects of poison.

ANTI'ENT, or **ANCIENT**, a term applied to things that existed long ago.

ANTI'ENT, in a military sense, implies the ensign or colours.

ANTI'ENT, in naval affairs, signifies the flag carried at the stem of a ship.

ANTILOGARITHM, is the logarithm of the co-sine, co-tangent, or secant. See the article **LOGARITHM**.

ANTILOGY, in literature, denotes an inconsistency between two or more passages of the same book.

ANTIMONARCHICAL, a name given to whatever opposes monarchical government.

ANTIMONY, in natural history, a blackish mineral substance, staining the hands, full of long, shining, needle-like striae, hard, brittle, and considerably heavy.

It is found in different parts of Europe, as Bohemia, Saxony, Transylvania, Hungary, and France, commonly in mines by itself, intermixed

with earthy or stony matters. Sometimes it is blended with the richer ores of silver, and renders the extraction of that metal difficult; antimony volatilizing a part of the silver, or, in the language of the miners, robbing the ore. Antimony is separated from its natural impurities by fusion in an earthen pot, whose bottom is perforated with a number of holes; the fluid antimony passing through, whilst the unfusible matters remain behind. The melting vessel is let into another pot sunk in the ground, and which serves as a receiver: this last is of a conical figure, and such accordingly is the shape of the loaves of antimony met with in the shops. The juncture of the two vessels is closely luted; the uppermost one covered, and a fire made round it; and several sets of this apparatus worked at once. In some places, instead of a pot with a perforated bottom, one is taken which has no bottom, and a perforated iron-plate placed betwixt it and the receiver; but the other method is to be preferred, as antimony in fusion is apt to dissolve a part of the iron.

Antimony is not a pure but a sulphurated semimetal. Thrown into the fire, it burns with a blue flame and sulphureous vapours: on digesting powdered antimony in aqua regia, the metallic part is dissolved, and the sulphur left. The sulphur of antimony, purified from the metallic part, is perfectly the same with the common brimstone of the shops, possessing the same properties, and answering the same uses: if the semimetal, freed from the sulphur naturally mixed with it, be afterwards melted with common brimstone, it resumes the appearance and qualities of crude antimony. Many have imagined, that this mineral, besides common sulphur, contains a golden or solar sulphur; because antimony purifies and heightens the colour of gold, and because it dissolves, as gold does, in aqua regia. But, with regard to the solubility in aqua regia, it is not the sulphureous, but the metallic matter of the antimony that dissolves: if nothing besides gold and antimony were acted upon by that menstruum, there might be some plausibility in the argument; but surely, when so many substances dissolve in it, as iron, copper, lead, tin, quicksilver, zinc, various earths, &c. solubility in aqua regia can be no proof of a solar impregnation. In the purification of gold, the sulphur of antimony has no other effect than common brimstone would equally produce: when gold, containing an admixture of other metals, is melted with antimony, the sulphur, having little affinity with its own semimetal, forsakes it, and unites with the silver, copper, or other metallic bodies mixed with the gold, but has no action on the gold itself: thus only the impurities of the gold are combined with the sulphur of the antimony into a scoria, which flows on the surface; whilst the gold and the semimetal of the antimony form one compound

compound at the bottom: if this compound be exposed to a strong fire, and a free draught or blast of air, it evaporates in fumes, and leaves the gold pure behind it. This process shews the resistance of gold to sulphur, and to the volatilizing power of the antimonial femimetal, but surely gives no foundation for imagining a solar sulphur to exist in antimony. As gold is the only metal (platina excepted) that totally resists antimony or its sulphur, this mineral has been called by the chemists *balneum solius solis*, *balneum regis*, *lupus*, *ul-tinus judex*, &c.

Hoffman has given an account of the different medicinal effects of antimony, as depending on its different treatments. He observes, that crude antimony, on account of the regulus being corrected by the sulphur, is not only safe, but in many cases a medicine of great service, both for man and other animals. That by simple fusion it acquires a degree of malignity; but a far greater if melted with half its weight of nitre, which consumes nearly all the sulphur, and leaves the regulus bare. That antimony, or its regulus, mixed with common salt, calcined over a gentle fire for several hours, and kept continually stirring, and afterwardsedulcorated with water, yields an ash-grey calx, which is so fixed as to bear a melting heat, and proves a mild and safe diaphoretic, void of any malignant or emetic quality. That antimony, by calcination with a gentle fire in an earthen vessel, in the open air, changes into a calx, which melts with difficulty, and which has no malignity. That if this calx be melted with a strong fire into glass, it becomes so active, that a few grains shall occasion violent vomiting and purging, or even mortal convulsions and inflammations. That the powdered regulus, calcined in a glass-vial placed in sand for several days, becomes a greyish diaphoretic powder; which reduced into regulus by fusion with powdered charcoal, nitre, and a little fat, proves again virulent. That when antimony is melted with one fourth its weight of salt of tartar, the whole poured into a mould, the scoria separated, and the more ponderous matter pulverized; the reddish powder thus obtained, is salutary: but that when antimony is melted with three or four times its weight of salt of tartar, both the scoriae and the regulus are virulent. That equal parts of antimony and nitre, melted together, yield a virulent mass; but one part of antimony, with two or three of nitre, is an useful diaphoretic. That on melting the diaphoretic calces with fat, charcoal, powder and nitre, the virulent regulus is revived. And thus one preparation may be changed into another, a salutary into a poisonous, and a poisonous into a salutary one.

Preparations of ANTIMONY. The preparations of antimony are extremely numerous. Lemery, in his Treatise on Antimony, describes no less than

two hundred; among which there are many good, and many useless ones. That gentleman was an excellent chemist, but an unhappy philosopher: we may depend on his operations, but we should distrust his theory. With regard to the antimonials, the greater number even of the common preparations is unnecessary; many of them differing little from one another, and all of them being either emetic or diaphoretic. The preparations of antimony may be ranged, according to the general operations by which they are produced, under four heads; those obtained by solution, by distillation, by sublimation, and by calcination.

Golden Sulphur of ANTIMONY. If powdered antimony be boiled in alkaline lixivium, or sope leys; the sulphur, and, by the mediation of the sulphur, a part of the regulus, will be dissolved into a yellowish red liquor. Any acid added to this solution precipitates what the alkaline liquor had taken up, in form of a yellowish or reddish powder, called sulphur, or golden sulphur of antimony; the powder which settles first is grosser and darker-coloured than those which follow; it appears of a deep reddish brown, whilst that which subsides last is of a pale yellow. The first is also the most active.

There are sundry variations of this process, both in regard to the solution and the precipitation. A difference in the manner of preparing the solution does not seem to affect the virtue of the medicine; but a difference in the acid used for the precipitation does; different acids having very different effects upon antimony: thus, whilst the marine renders it highly corrosive, or emetic, the addition of the nitrous destroys the virulence of both preparations, and renders the antimony mildly diaphoretic.

All the antimonial sulphurs are emetic and cathartic: those which precipitate first are much more strongly so than the powder which falls last; the last precipitates, if they prove emetic once or twice, cease to have that effect upon continuing their use, and act chiefly as diaphoretics; and hence are greatly to be preferred to the first. A powder is vended by the Carthusian friars in Paris, at a considerable price, as a specific against sundry disorders; commonly called *poudre des char-troux*, but by themselves *kermes mineral*. See *KERMES Mineral*.

Butter of ANTIMONY. For dissolving the regulus of antimony without the sulphur, the most concentrated spirit of salt, or aqua regis, is necessary. For obtaining the solution in spirit of salt, mercury sublimate and powdered antimony are mixed together, and digested in a glass-retort placed in sand: the marine acid in the sublimate forsakes the mercury, and corrodes or dissolves the antimonial regulus; whilst the mercury of the sublimate unites with the antimonial sulphur. But the solution of the regulus, thus effected, cannot

cannot be commodiously separated from the other matter but by distillation: on increasing the fire, the regulus arises, dissolved in the concentrated acid not in a liquid form, but in that of a thick unctuous substance, like butter; hence called butter of antimony. The butter liquifies by heat; and requires the cautious application of a live coal to melt it down from the neck of the retort. By rectification or exposure to the air, it becomes fluid, but still retains the name of butter. The addition of water, either in its thick or fluid state, by diluting the acid, precipitates the regulus dissolved in it. The proportions of sublimate and antimony commonly employed, are three parts of the former to one of the latter.

Flowers of ANTIMONY. These are prepared by subliming either the crude antimony, or the regulus, with a number of aludels; the fire being kept up strong, and a blast of air impelled occasionally by a pair of bellows upon the matter in the subliming pot, to promote its evaporation. The antimonial flowers are in general of great activity, and though recommended by some as arcana in particular disorders, require to be used with great caution.

Cinnabar of ANTIMONY. After the distillation of butter of antimony, the mercury and the sulphur, contained in the ingredients made use of for that process, remain behind in the retort. This compound appears of a black colour; urged with a stronger fire than that which elevated the butter, it sublimes into a red mass, called cinnabar of antimony. This cinnabar has been by many preferred to the common factitious cinnabar, but on no just foundation: they both consist of mercury combined with sulphur; and the only difference betwixt them is, that the antimonial cinnabar contains somewhat more sulphur than the other, and hence appears of a darker colour.

Glass of ANTIMONY. This is chiefly prepared by some particular persons at Amsterdam and Rouen, who have furnaces contrived on purpose for calcining large quantities of antimony with little expence of fuel. The glass may be easily made, by urging the calx in a crucible with a strong fire, and throwing in, towards the end, a little crude antimony or sulphur. When the vitrefication is completed, the glass is poured on a copper plate, or on a flat stone. The glass of antimony is used only for making other emetic preparations, as the emetic wine, &c.

Hepar ANTIMONII, liver of antimony. Equal parts of crude antimony and nitre mixed together, set on fire and suffered to deflagrate in an iron mortar, which may be covered with a perforated plate, or injected by degrees into an ignited crucible, yield a liver-coloured mass, called hepar antimonii, which pulverized and edulcorated with water is named crocus metallorum. Two, three,

or even one grain of either of these preparations occasion violent anxieties and vomitings; though a dog will bear a dram, and a horse a whole ounce, without being apparently any otherwise affected than in having the alvine discharge increased. The emetic wine, emetic tartar, and other medicines made from the glass, may also be made from the crocus.

Diaphoretic ANTIMONY. One part of antimony and two and a half or three of nitre, mixed together and deflagrated, yield a calx void of all emetic power, called diaphoretic antimony.

The martial Diaphoretic ANTIMONY, or Specific Stomachic of Poterius, is prepared by melting equal parts of antimony and iron filings, injecting upon them in fusion thrice their weight of powdered nitre, and after the detonation is over, edulcorating and drying the calx. The jovial diaphoretic antimony, or antihæctic of Poterius, is made in the same manner, from a mixture of tin and martial regulus of antimony, in the proportion of one part of tin to four of the regulus. This preparation has no claim to antihæctic virtues, nor indeed to any salutary operation.

Regulus of ANTIMONY. The simple regulus of antimony is commonly prepared from equal parts of antimony, nitre, and tartar, mixed together and injected into a red-hot crucible: when the whole is thrown in, the crucible is to be covered, a strong fire kept up for a quarter of an hour, and the matter poured out into a conical mould previously warmed and rubbed with grease. The yield of regulus will be larger, if the quantity of nitre is diminished; or if the nitre and tartar are deflagrated together, in the proportion of one part of the former to two of the latter, before their mixture with the antimony. The salts are reduced by the deflagration into a black alkaline coal; this is the substance commonly used by the chemists for promoting the fusion of metallic calces, and reviving them into their metallic form, and hence is distinguished by the name of black flux. Some have been accustomed to save the expence of nitre, by taking pot-ash or other alkaline salts: the regulus is in both cases the same. When the matter is grown cold, the scoriæ found on the surface are knocked off, the regulus reduced into coarse powder, melted in a fresh crucible, and about one fourth its weight of purified nitre injected upon it; this depuration may be twice or thrice repeated with smaller proportions of nitre, till the scoriæ become semitransparent and of an amber colour.

Martial Regulus of ANTIMONY. This preparation is obtained very commodiously from four parts of powdered antimony, two parts of iron nails or wire, and one part of nitre. The iron, made red hot in a crucible, soon melts upon adding the antimony; after which the nitre is to be injected, the crucible covered, and the matter, when

U u brought

brought into thin fusion, poured expeditiously into a warm greased cone. The regulus freed from the scoræ is to be melted afresh, with about one fourth its weight of nitre; and this purification, if necessary, repeated. If the regulus retains any superfluous iron, it will look greyish, spongy, prove hard to break, and difficult of fusion: in such case, the scorification of all the iron, by means of nitre, would be a tedious work; but the addition of a little crude antimony, or common sulphur, will absorb it at once; and the injection of nitre will now soon complete the purification, and render the regulus of a sparkling white colour. The scoræ are yellow and semitransparent, like amber; if the quantity of nitre has not been too large, they prove an excessively strong fiery alkali, distinguished by the name of *nitrum causticum*. The yellow scoræ, which separate in the depuration of the simple regulus with nitre, are likewise alkaline, but want the causticity of these: the scoræ produced from the martial regulus, by calcination with tartar, take fire on being exposed to the air. If either regulus, after due purification, be hastily poured into the mould whilst in exceeding thin fusion, and if the quantity of scoræ covering the surface is considerable, the regulus, when grown cold, exhibits the appearance of a star upon the top. For producing this appearance, there is no occasion for any particular sort of antimony, or any particular iron, or any particular constellation, or season, or weather, as many have idly imagined; the whole depending upon the circumstance abovementioned.

The simple regulus is cast into cups, which, like those made from the glass, communicate an emetic quality to wines; and into pills, like shot, which prove strongly purgative, and do not lose their virtue in passing through the body; whence their name *pilulæ perpetuæ*.

Tincture of ANTIMONY. There are various tinctures of antimony, which some have fondly imagined to participate of solar, veneereal, antimonial, and other impregnations. They appear to be all no other than simple alkaline tinctures; their colour proceeding from the oily matter of the spirit of wine, heightened by the caustic alkali. Spirit of wine consists of an oil highly attenuated and combined with water into one seemingly homogene liquor: if the most highly rectified spirit, which exhibits no mark of any phlegm, be employed for making these tinctures, it will now yield in distillation a good quantity of water; the oil, before combined with that water, having been absorbed by the alkali. If caustic alkaline salt, alone, be poured hot into rectified spirit, and the mixture digested for some time, a tincture will be obtained, not distinguishable from the antimonial. If sulphur be added in either case, the tincture will receive a considerable taste and smell from that ingredient.

ANTINOMIANS, a sect of heretics so called, because they rejected the law as of no use under the Gospel dispensation. The word is derived from the Greek *ἀντι*, against, and *νόμος*, the law.

They held that good works were not profitable, nor evil works pernicious to the soul; that God never punished any nation for the sins of its inhabitants; that murder, adultery, drunkenness, and such like, were real and damnable crimes in others, but not in them, just as equivocation and lying was no sin in faithful Abraham; that the children of God, being once assured of their salvation, can sin no more, or as Mr. Wesley says, are in a sinless state; that no man's conscience should be offended because it is stained with guilt; that a hypocrite may have all the graces which Adam had before his fall; that faith in Jesus Christ is the only and all-sufficient means of salvation; that God regards no one for his piety and virtue; with many other absurd tenets too tedious to enumerate. One John Agricola is said to have been the author of this sect, in the year 1535.

ANTIPARALLELS, in geometry, are those lines, as DE and BC (Plate X. fig. 5.) which form the same angles as ADE and BCA, with the two lines AB and CA cutting them, but in contrary ways or opposite directions, like parallel lines. Mr. Leibnitz in the *Acta Erudit.* an. 1691, p. 279. calls those lines antiparallels, as GI, HK (plate X. fig. 6.) which cut two parallels AD and EF, so that the outward angle ABI, together with the inward one ACK, be equal to a right angle. When the sides AB and AC of a triangle, as ABC (Plate X. fig. 5.) are cut by a line DE, antiparallel to the base BC, the said sides are cut reciprocally proportional by the said line DE; that is, AD : BD :: EC : AE, the triangles ADE and ACB being similar or equiangular.

ANTIPATHY, a natural aversion of one body to another; the opposite to sympathy.

The word is Greek, *αντιπαθια*, and compounded of *αντι*, against, and *παθος*, affection.

ANTIPERISTALTIC *Motion of the Intestines*, is a motion directly opposite to the peristaltic. See the article PERISTALTIC.

ANTIPERISTASIS, in the peripatetic philosophy, an imaginary method of increasing the power or force of any quality, by the opposition of its contrary. Thus cold is said to augment the heat of fire; a doctrine now sufficiently exploded.

The word is Greek, *αντιπερισταςις*, and compounded of *αντι*, about, and *περιεμει*, to encompass, or surround.

ANTIPHONY, alternate singing; as when a congregation, divided into two parts, repeats or sings a psalm or anthem, verse for verse, one after the other.

The word is compounded of the Greek, *anti*, opposite, and *φωνη*, a voice.

Antiphony is opposed to symphony, which is singing jointly, or all together. St. Austin carries the original of this way of singing, in the western church, no higher than the time of St. Ambrose, when it was first introduced into the church of Milan; which example was soon followed by the other western churches. What was the original of it in the eastern church, is not so certainly agreed upon by writers, either ancient or modern. It was a method of singing so taking and delightful, that it was often used, when only two or three were met together for private devotion. And Socrates particularly remarks of the emperor Theodosius the Younger, and his sisters, that they sung alternate hymns together every morning in the royal palace.

ANTIPHRAISIS, in rhetoric, a figure, by which, in saying one thing, they mean the contrary. See the article IRONY.

The word is Greek, and compounded of *anti*, opposite, and *φωνη*, to speak.

ANTIPODES, in geography, a name given to such as live diametrically opposite to each other on opposite meridians and parallels: at 180 degrees distant they have all things contrary; the one has summer and long days, or no nights, at the same time as the other has winter, short days, or perpetual nights; it is likewise 12 o'clock at noon with one when it is midnight with the other.

When we consider that the horizon of one is 90 degrees distant from the zenith of the other, it will be easy to conceive that when any celestial object rises to one in the east, it sets to the other in the east; and when it sets to one in the west, it rises to the other in the west.

In former times it was considered as a fable for any one to say people walked with their feet opposite to ours; nor could they conceive that men or trees could subsist suspended in air with their feet upwards; not considering that upwards and downwards signify nothing more than a less or greater distance from the center of the earth, to which all heavy bodies gravitate.

Plato is said to have first hinted that there was any such thing as antipodes, and is supposed to be the first inventor of the name. We need not wonder that this great philosopher concluded the existence of antipodes, when he before apprehended the earth to be spherical. However, their existence we are greatly disputed by the ancients, especially by St. Augustine, Lactantius, Boniface archbishop of Mentz, and many others, which held it even to be heresy to believe there were any inhabitants on the opposite side of the globe.

In the History of the Academy of Sciences 1741, the antipodes are considered in the following manner,

with regard to their being diametrically opposite on the globe to each other:

If we suppose that a perpendicular or vertical line be drawn through any place whatever, and which consequently passes through the zenith of that place, the opposite part on the surface of the globe, which this vertical line continued would cut, is the situation of the antipodes to that place: but this depends on a supposition of the earth's being a perfect sphere; for if the earth be not a perfect sphere, but an oblate or prolate spheroid, there are no reciprocal antipodes: that is, for instance, if a line be drawn through the zenith of London, and center of that city, which is in the northern hemisphere, this line would cut the southern hemisphere in a point which will be diametrically opposite to London; but London then will not be the antipodes to this place. Thus the reciprocal equality of situation, latitude, day and night, in the opposite hemispheres at six months distance, and all that we are used to include in the idea of antipodes, as inseparable from it, is no longer so; and must alter, in proportion as the figure of the earth deviates from a true sphere. A little attention will convince us of this.

What we have advanced is founded on this position, that the sphere, or, to render the theory more simple, the circle, is the only regular figure which all diametrical lines drawn through the center cut at right angles: therefore, in every figure terminated by another kind of curve, to instance in the ellipsis, the perpendicular drawn to one of its foci, or to its tangent, except the two axes which correspond to the polar line, or a diameter drawn at the equator, will not pass through the center, nor cut the opposite part of the ellipsis at right angles; therefore the nadir of Paris or London is not the zenith of their respective antipodes. So if, in the center of London or Paris, a perpendicular column were erected, and another in their respective antipodes, it would not make the same right-line, but would form an angle more or less acute, in proportion as the ellipsis departed more or less from a circle; and consequently the latitude, days, nights, seasons, &c. would alter in the same proportion. Places situated under either pole, or on the equator, are excepted for the reason we have before suggested; because, in the former case, it is one of the axes of the ellipsis that joins both foci, and in the latter it is always a circle, the other axis of which is the diameter of the ellipsis; the spheroid, however oblate or prolate, being always supposed to result from the revolution of the elliptical meridian round the axis of the world.

ANTIPOPE, in the Romish church, implies a person elected pope in an irregular manner, in opposition to another.

ANTIPTOSIS, in rhetoric, is a figure which puts one case for another.

The word is Greek, and compounded of *ἀντί*, opposite, and *παις*, a calf.

ANTIQUARIAN Society.—A society of antiquaries was formed in the city of London, about the year 1580, by some of the most learned men in the kingdom; but having been frequently interrupted and discontinued, very little can be said concerning the same till the year 1717, when it was again revived by a number of gentlemen, studious of antiquity in general, but more particularly desirous to obtain all possible knowledge of the antiquities of their own country. With this view they agreed to meet one evening in every week under certain regulations; they encouraged correspondencies with all parts of the kingdom; they subscribed an annual sum to defray the expence of engraving on copper-plates what should be thought deserving to be so preserved, and limited their number to 100. And in this manner they continued their weekly meeting with great reputation, till his majesty king George II. was graciously pleased to grant them a royal charter of incorporation, dated November 2, 1751, and to declare himself their founder and patron.

Under this charter they became a body corporate, by the name of the Society of Antiquaries of London, with a power to have and use a common seal, to sue and be sued, and to take, hold, and enjoy, by purchase, gift, or otherwise, any lands, tenements, or hereditaments, not exceeding in the whole one thousand pounds per annum. And it is therein directed, that the council of the said society shall at all times consist of twenty-one persons, the president for the time being always to be one; and Martin Folkes, Esq; was by charter appointed the first president, and also twenty other persons therein named to be the first council, empowering them, within two months from the date thereof, to nominate, choose, and admit, as fellows of the said society, such persons as should excel in the knowledge of the antiquities and history of this and other nations, and be eminent for piety, virtue, integrity, and loyalty. This first president and council were to continue till the 23d day of April next ensuing; on which day, in every year hereafter, the council and fellows assembled to nominate and elect a president and council for the ensuing year: and it was particularly directed that eleven of the former council should be continued, and ten other persons chosen out of the members of the society; ten and no more of the council being to be changed annually. The president is empowered to nominate four persons of the council to be his deputies, and supply his place, in case of sickness or absence; and the president, council, fellows, or any twenty-one or more, are empowered to make statutes, rules, orders, and bye-laws, for the government and direction of the said society, their estates, goods, &c. and for the admission and

admission of all and every the members and officers thereof. And the president, council, and fellows, may at any time appoint treasurers, secretaries, and clerks, may have and employ one serjeant at mace, and such other servants as they think necessary. And lastly, if at any time abuses or differences should arise, the archbishop of Canterbury, the lord chancellor or keeper of the great seal, and the lord privy seal, and the two secretaries of state for the time being, were appointed visitors, with the full power for any three of them to compose and redress such differences and abuses. Provision is also made to fill up any vacancies that should happen by the death of the president or any of the council.

On the receipt of this charter, the first president and council nominated and admitted, by a writing dated the 14th of November 1757, all the former members, together with some others, in the whole one hundred and twenty-one, to be fellows of the said society of antiquaries of London; and soon after drew up a body of statutes for the good government thereof, which was unanimously agreed to and confirmed in the month of July 1752.

It was enacted, that the number of members should not exceed one hundred and fifty; but that number being very soon filled up, and several men of quality and fortune, as well as persons of great learning and eminence, being continually applying to become members, which they could not be till the vacancies should happen by death, the society thought proper, in the year 1755, to enlarge their number to one hundred and eighty (to which they are limited at present) exclusive of peers, privy-counsellors, and judges, that should be chosen after that time. A little before this, the society gave up the management of their estate and revenues, the payment of monies, and the publication of their papers and drawings, which were before in the body in general, and thereby attended with many inconveniences, intirely to the care of their council, which are now a standing committee for that purpose; and thereby the government of this society is become nearly the same as that of the Royal Society, which was doubtless a proper pattern to copy after.

On the 23d of April, being St. George's day, the society annually elect their council and officers, viz. a president, a treasurer, two secretaries, and a director, who has the care of all their publications. Then the president appoints four of the council to be his deputies, or vice-presidents: and after the election is over, the society dine together at their own expence. Martin Folkes, Esq; was annually elected president, till his death in 1754, since which time the Right Hon. Lord Willoughby of Parham was every year chosen till his decease in 1765.

Every person desirous to be elected a fellow of this society, except peers, privy-counsellors, or judges.

judges of Great Britain or Ireland, must be recommended by three or more of the members, in a paper signed by themselves, specifying the name, addition, profession, and chief qualification of the candidate, and also the place of his abode. When this has been read at one of the society's meetings, and then hung up in their public room, during the time of four other meetings, the election is determined by ballot. Peers, privy-counsellors, and judges of Great Britain or Ireland, if proposed by any single member, must be balloted for immediately. Every new member must pay an admission-fee of five guineas, and sign the obligation, whereby he promises that he will, to the utmost of his power, promote the honour and interest of the society, and observe the statutes and orders thereof; which being done, he is led up to the chair, when the president or vice-president rising takes him by the hand, and says, "I do, by the authority and in the name of the society of antiquaries of London, admit you a fellow thereof."

Every member must further pay one guinea annually for the use of the society, or ten guineas at once in lieu of all contributions.

The meetings of this society are on Thursday evenings weekly, from about six till nine o'clock, at their house in Chancery-lane. Their business is to receive, read, and consider all informations from their own members or others, concerning the antiquities of all nations; (for which purpose they admit eminent foreigners to be corresponding members) but they more particularly attend to the study of the ancient history, customs, manners, grants, charters, coins, medals, camps, churches, cities, and all monuments whatever, ecclesiastical, military, or civil, which are found in or relate to Great Britain and Ireland; and the communications they have received concerning these matters must be very valuable, as may be judged by the many curious remains of antiquity they have caused to be engraved on copper-plates, and permitted lately to be sold; though as yet they have not thought fit to publish any of their dissertations. They have a small but choice library, which is increasing daily; also a fine collection of prints and drawings.

ANTIQUARY, a person who studies and searches after remains of antiquity.

ANTIQUE, among architects, a building executed when architecture was in its utmost perfection among the ancient Greeks and Romans; that is, from the age of Alexander the Great to the reign of the emperor Phocas, about the year of Christ 600, when Italy was over-run by Goths and Vandals. Thus antique architecture is distinguished from or opposed to modern and modern architecture.

ANTIRRHINUM, calve's snout, or snap-dragon, in botany, a genus of didynamious plants, producing a monopetalous personated flower, di-

vided into two lips, the upper one of which is bifid and reflexed on each side, the lower lip is trifid and obtuse: the fruit is a roundish bilocular capsule, containing many angular seeds. Some sorts of antirrhinum grow wild on the tops of old walls, where they make an agreeable appearance, and thrive much better than if cultivated in gardens.

ANTISAGOGE, in rhetoric, the same with concession. See the article **CONCESSION**.

ANTISCH, in geography, people who inhabit different sides of the equator, but may have different longitudes and latitudes. Thus the people of the north are antischi to those of the south, and their shadows are projected different ways.

ANTISCORBUTICS, among physicians, medicines good in all scorbutic cases. See **SCURVY**.

ANTISEPTICS, among physicians, a name given to all substances that resist putrefaction.

The word is formed from the Greek, *anti*, against, and *σπας*, to putrefy.

Dr. Pringle, in an appendix to his Observations on the Diseases of the Army, has given a very curious and useful set of experiments on antiseptics.

ANTISIGMA, among the ancient grammarians, implies a note or sentence affixed to those verses whose order was to be changed.

ANTISTROPHE, in lyric and dramatic poetry, is the name of the second stanza of the ancient ode and chorus, in singing of which the dance was inverted. Most of the odes, as well as tragic choruses, were composed to be sung; the former of these either at the entertainments given by the conquerors (to whom they were inscribed) or by their friends on account of their victories, or at solemn sacrifices made to the gods upon those occasions.

They consisted generally of three stanzas; the first of which was called strophe, the second antistrophe, and the third epode. When the strophe was sung, they danced to the right round the altar; and when the antistrophe was sung, returned back again by the left. This is the reason why the strophe and antistrophe consisted exactly of the same length and measure. When the dancers were returned from the place where they set out, before they renewed the dance they stood still while the epode was sung. Perhaps the strophe and antistrophe, as it required so much breath to sing and dance at the same time, were only a kind of recitative, while the epode was the more complete air. See **EPODE** and **STROPHE**.

ANTISTROPHE, in grammar or rhetoric, signifies a sort of repartee, whereby two terms or things, mutually dependent on each other, are reciprocally inverted: it is a sort of playing with the words; as in this line of Pope's,

Whom folly pleases, and whose follies please.

ANTITACTES, in ecclesiastical history, a name given to a branch of the Gnostics, who held that God was good and just, but that a creature had created evil: that we are therefore to oppose this author of evil, in order to avenge God of his enemy.

The word is derived from the Greek, *antitacten*, to oppose.

ANTITHENAR, in anatomy, the name of a muscle, generally called adductor indicis. See the article *ADDUCTOR INDICIS*.

ANTITHESIS, in rhetoric, a figure of speech, which consists in opposing the thoughts to each other, in order to place their opposite qualities in a more conspicuous point of light.

The writings of the ancients abound with this figure. Cicero, in his oration for Cluentius, says, *Vicit pudorem libido, timorem audacia, rationem amentia*.

ANTITHESIS, in grammar, is a figure whereby one letter is substituted in the room of another; as when Virgil says *illi for illi*, in order to make a kind of opposition.

ANTITHETARIUS, a term occurring in the title of a chapter of the laws of Canutus, but not in the chapter itself. It signifies a person who endeavours to acquit himself of the crime laid to his charge, by charging his accuser with the same fact.

ANTITRAGUS, in anatomy, the part of the external ear opposed to the tragus. See *EAR* and *TRAGUS*.

ANTITRINITARIANS, is a general name given to those who deny the mystery of the trinity, that there are three persons, and but one God. Under this title are comprehended the Macedonians and Samosatians, but more particularly the Arians and Socinians. See *ARIAN* and *SOCINIAN*.

ANTITYPE, a word which is taken from the Greek, and signifies a pattern, model, example, &c.

There are two places in the New Testament, where this word occurs, which have occasioned some doubt and disputation amongst commentators. One is in the epistle to the Hebrews, ix. 24. where the word *αντυπα* is rendered *figures*; "Christ is not entered into the holy places made with hands, which are *figures* of the true." It does not seem in this place to be well translated: the apostle in this chapter had been drawing a comparison between Christ and the high-priest, who entered into the holy of holies once a year, not without blood, to make an atonement for the sins of the people: he then says, that our Saviour is not entered into the holy of holies, which was made with hands, as that of the tabernacle was; for this was only--What? An antitype, a place built after the model, of the true: for God commanded Moses (Exod. xxv. 40.) to make the tabernacle after the model that was shewn him in the mount.

In the first epistle of St. Peter, iii. 21. baptism is called the antitype of the ark, because in *that* some were saved by water. This is by no means clearly translated in our version; "The like *figure* whereunto, even baptism, doth also now save us." The whole passage would have been better rendered thus: "While the ark was preparing, wherein a few, that is, eight souls, were saved by water: in imitation of which (*ω αντυπον*) or as a resemblance of which, baptism doth even now save us." The ark was the type or figure, baptism was the antitype or accomplishment of that figure.

The word antitype was frequently made use of in the Greek church, to signify the bread and wine after consecration.

ANTLER, among sportsmen, implies a start or branch of a deer's horn.

Brow **ANTLER** signifies the branch next the head.

Bes **ANTLER**, the branch next above the brow antler.

ANTŒCI, in geography, are those people which live on the same meridian on different sides of the equator, but at equal distances; consequently, if their latitudes be greater than the sun's declination, their shadows will be projected different ways. They have noon at the same time, but it is winter with one when it is summer with the other; and the night of one is equal to the day of the other. If the antœci both turn their faces towards the equator, the stars and planets will rise to one on the right hand, and to the other on the left.

ANTONIAN Water, in the materia medica, the name of a medicinal water of Germany, remarkably pleasant to the taste, and of service in many cases as a medicine.

It is very temperate, not too strongly operating either by stool or urine: and hence it is a very proper drink for persons in chronic and many acute diseases, either alone, or mixed with wine, to supply the place of malt liquor, which is proper but in very few diseases. A long use of it alone may also prove of considerable service in hypochondriac cases. *Hoffman*.

ANTONOMASIA, in rhetoric, a figure by which the noun appellative is used instead of a proper name, and the contrary.

The word is compounded of the Greek, *αντι*, for, and *ονομα*, a name.

Thus, because Sardanapalus was a voluptuous prince, and Nero a cruel emperor, we give an epicure the name of Sardanapalus, and a barbarous prince the appellation of Nero.

ANTRUM Hgymorianum, in anatomy, is a cavity discovered in the maxillary bone, called also sinus maxillaris.

ANTRUM Pylori, in anatomy, is a large cavity at the bottom of the pylorus. See *PYLORUS*.

ANUBIS, in mythology, a name given to Mercury,

cury, who was worshipped by the Egyptians under the figure of a dog.

Diodorus Siculus tells us, that Anubis, following his father Osiris to war, bore the ensign of a dog on his shield; for which reason he was worshipped, after his death, under the figure of a dog.

ANVIL, in mechanics, is an instrument on which the smith hammers or forges his work. The uppermost face of the anvil should be very flat and smooth, and so hard that a file will not penetrate it; it is generally placed on a large wooden block; at one end there is sometimes a round pike, or beak-iron, for the rounding of hollow work, or bending iron into different curves.

ANUS, in anatomy, the extremity of the intestine rectum, or orifice of the fundament. It is surrounded with a large quantity of fat, that it may easily dilate in discharging its contents, and is furnished with three muscles, called elevatores and sphincter. See SPHINCTER.

Anus is also the name of a small aperture in the third ventricle of the brain, leading to the fourth ventricle of the cerebellum.

AONIDES, in mythology, one of the many appellations of the muses, so called from the Aonian mountains in Bæotia, where they were feigned to reside.

AORASIA, in antiquity, the invisibility of the gods.

The word is Greek, *αορασια*, and derived from *α*, priv. and *οραω*, to see.

The opinion of the ancients, with regard to the appearance of the gods to men, was, that they never shewed themselves face to face, but were known from their backs as they withdrew: whence it followed, according to them, that every being they had time to look at in the face, was not a deity. Neptune assumed the form of Calchas to speak to the two Ajaxes; but they knew him not till he turned his back to leave them; and discovered the god by his majestic step, as he went from them. Venus appeared to Æneas in the character of a huntress; but her son knew her not till she departed from him; her divinity was betrayed, if we may use the word, by her radiant head, her flowing robe, and her majestic pace.

AORIST, in the Greek and French grammars, is the name of a tense, which denotes the preter indefinite, or indeterminate. The word is compounded of *α* priv. and *ορσ*, a limit. Thus, *I have made*, is the preterperfect tense, because it speaks absolutely; *I made*, is the aorist, because it is not determinate, for there wants a word to fix the time, as, *I made yesterday*.

The aorist is not made use of, except in speaking of a time distinct from the present: thus, if we would express ourselves with propriety, we should say, *I read Plutarch formerly*; and, *I have read Plutarch*

this morning; because this morning is looked upon as part of the present day.

AORTA, in anatomy, the great artery which rises immediately from the left ventricle of the heart, and thence distributed to all parts of the body. It is divided into two grand trunks, distinguished by the epithets ascending and descending. See the article ARTERY.

APAGOGICAL *Demonstration*, implies an indirect method of proving the truth of a proposition, by shewing the absurdity of the contrary.

The word is formed from the Greek, *απο*, from, and *αγω*, to bring, or draw.

APANAGE, or APENSAIRE, in the French customs, are lands assigned by the sovereign for the subsistence of his younger sons, and which revert to the crown upon failure of male issue in that branch to which the lands were granted.

APARINE, goose-grass, or clivers, in botany, a plant with a slender fibrous root, and thin, quadrangular, rough, jointed, climbing stalks. At every knot there are placed five or seven narrow rough leaves in the form of a star; the flower is campanulated and monopetalous, containing four subulated filaments; the fruit, when ripe, is dry, covered with a blackish skin, consisting of two globose berries joined together, and containing single roundish seeds. This plant grows wild in many places, and flowers in May or June: it is said to be warm and dry, and is recommended in cachexies, promoting both urine and sweat. The juice of this plant is efficacious in dropical disorders, evacuating the water by urine.

APARTMENT, a portion, or part of an house, containing the necessary conveniencies for a person to reside in it.

APATHY, among the ancient philosophers, implied an utter privation of passion, and an insensibility of pain.

The word is compounded of *α*, priv. and *παθος*, affection.

The Stoics affected an entire apathy; they considered it as the highest wisdom to enjoy a perfect calmness or tranquility of mind, incapable of being ruffled by either pleasure or pain.

The primitive Christians used the word to express a contempt for the things of this world.

APATURIA, in antiquity, a solemn feast celebrated by the Athenians in honour of Bacchus.

APE, in natural history, the English name of an animal of the monkey kind. See MONKEY.

A-PEEK, in the marine, the anchor is said to be a-peek when so much of the cable is drawn into the ship as to bring her perpendicularly over the spot on which the anchor is laid.

APELLITES, the name of a sect of heretics who sprang up in the second century, and so called from their founder Apelles, who was a disciple of Marcion. They maintained that Christ had only a bodily

a bodily appearance, but not a real body of flesh and blood: that when he descended from heaven he took upon him an aerial form, which at his ascension dissolved again into air. They denied the resurrection of the body, and professed the same doctrine as the Marcionites.

APEPSY, *Apepsia*, among physicians, implies crudity, or a want of digestion.

The word is Greek, and compounded of *α*, priv. and *ασατα*, to concoct.

APERIENS *Paiphebrum rebus*, in anatomy, a muscle in the eye-lid. It arises sharp and fleshy from the profoundest part of the orbit, near the place where the optic nerve is transmitted, passing directly over the musculus attollens; it becomes tendinous, as it marches over the ball of the eye; whence it still grows broader and thinner, till it is inserted into the whole superior part of the upper eye-lid.

APERIENTS, in the materia medica, such medicines as facilitate the circulation of the juices in their containing vessels, by removing all obstructions. See the article **DEOBSTRUENTS**.

APERTURE, in general, signifies the opening of any thing; or a hole, cleft, or vacant place in some continuous subject.

APERTURE, in geometry, is the opening of two right lines, which inclining towards each other, meet in a point, and form an angle, which is called the aperture; or the angle contained between the two legs of a pair of compasses, when opened to any radius, is properly called the aperture.

APERTURE, in architecture, are doors, windows, chimneys, &c. It is a rule among good architects to have as few apertures as convenience will admit, because the strength of the building is diminished in proportion to the number of apertures.

APERTURE, in optics, is a hole next the object glass of a telescope, microscope, &c. through which the light and image of the objects are transmitted down the tube to the eye. The diameter of this aperture or hole, (which is mostly cut in a small piece of wood, brass, tin, &c. fitted to the shape of the tube) is best determined by practice; as all theory will be found to vary from the truth, for different object glasses of the same dimensions are found to require different apertures, as well as different objects, according as they are more or less luminous: however, it may not be amiss to approach as near as possible by theory, and complete the aperture by observation and experiment. Thus, for example, to find the aperture nearly, say, As 10 is to 1, so is the square root of the distance of the focus of any glass multiplied by 30, to its aperture; then having provided yourself with some paste-board paper made black, and cut in circular pieces, with apertures gradually diminishing and increasing in diameter from the aperture found by the above

proportion, place them on the object glass, and by looking at any object, you will quickly find which shews the object most distinct. Likewise by trying at different objects, (as the planets) you may find which aperture suits best for each; and by marking each paper aperture, have them always at hand to use according to the object you would view. The diameter of the aperture of an object glass, by being made of different lengths, does not increase or diminish the area of the object, but shews it to the eye more or less distinct, by admitting a quantity of luminous rays which obscures the object, by reason that the great glare dazzles the eye.

APERTURE, is also understood of that part of the object-glass itself which covers the former, and which is left pervious to the rays. See **TELESCOPE**.

APETALOUS, among botanists, a term given for those flowers which are destitute of corolla or petals.

APEX, in geometry, the same with vertex. See **VERTEX**.

APHACA, in botany, a kind of vetch classed by Linnaeus amongst the lathyrus. See the article **LATHYRUS**.

APHÆRESIS, in grammar, is a figure by which a letter or syllable is cut off from the beginning of a word.

APHANES, in botany, a genus of plants producing apetalous flowers with two egg-shaped germs, and two ovate acuminate seeds approaching nearly to the alchimilla.

APHEA, in mythology, a goddess worshipped by the Cretans and people of Ægina.

Aphea, before she was made a deity, went by the name of Britomartis in Crete. Her passion for hunting attached her to the train of Diana, and dedicated her virginity to the goddess; to avoid the pursuit of Minos, who was desperately in love with her, she threw herself into the sea, and was taken up in the nets of some fishermen. Diana rewarded her virtue with the honours of immortality. Britomartis afterwards appeared to the people of Ægina, who paid adoration to her under the name of Aphea.

APHELION, in astronomy, is that point in the elliptic orbit of any planet, which is at the greatest distance from the focus of the ellipse, or that point where the planet is at its greatest distance from the sun. Thus suppose AHP (Plate X. fig. 1.) to be the elliptic orbit of any planet, C, the center, and S, the focus or sun; then the point A, which is at the greatest distance from S, is called the aphe- lion, in opposition to P, the perhelion, which is the nearest point in the orbit to S the focus, or place of the sun.—Every planet moves, quickest when in or near the perhelion, and slowest when in the aphe- lion. Likewise their apparent diameters

are

lofts or upper rooms; but this is not so proper for them. If a person intends to have a considerable store of bees, a square plat must be made by itself, proportioned to the number of bees intended to be kept, not quite a square, being rather longer extended from east to west, but so contrived that they may have as much of the morning and evening sun as possible. The apiary should be securely defended from high winds on either side, either naturally by hills, trees, &c. or artificially by houses, barns, walls, &c. It is also to be well fenced from cattle, especially hogs, and from all sorts of fowl, their dung being very prejudicial to them; neither should there be any ill smells, nor any poultry kept near the place. The apiary should be furnished with stools or benches of wood or stone; but the first is best, stone being hot in summer, and cold in winter: these are placed at different heights, but about twelve inches is a good height; they should be set a little shelving, that the rain may run off; they should also be two or three inches wider than the hives set upon them, and at least five feet distant from the other.

To have a compleat apiary, for every stock of bees intended to be kept, make a cot or house about two feet square, and two and a half high, set on four legs about ten inches above the ground, covered over with boards or tiles to keep off the rain, the back or north side being closed up; and the sides, facing the east and west, to have doors with latches and hasps to them; the fore or south side to have a falling-door to cover one half thereof, which is to be raised up at pleasure; and in summer-time serves for a pent-house, not only to keep off the beating rains from the hives, but to defend them from the extreme heat of the sun, which at noon-day is apt to melt the honey. The other lower half should have two small doors to open to either hand, which will serve to defend the doors or holes of the hives from injurious winds: all the doors may be fastened in winter, when the weather is too cold; or in summer, when it is too hot for the bees, only making a little open square at the bottom of the little doors against the bee-hole, that the bees may have some liberty to fly abroad, after the doors have been shut: by means of the slide doors, especially if the west door be made to open to the right hand, a person may sit safe, and see the several workings of the bees in glass hives, if any such are used; if not at these places he may order, view, and observe them better than when they stand on naked stools, and with less offence to the bees, and more security to himself.

In the winter season, if the apiary stand cool, good sweet straw may be stuffed within the doors about the hives, to keep them warm; but extremity of cold does not hurt bees so much in winter as wet, from which these cases best preserve them; or as light, and the warm beams of the sun, at

such time when there is no provision abroad for them, against which this house or cot is the best preservative; for, when the doors are shut, though the sun shine, yet they are insensible of it, the hives standing six or eight inches within the doors; whereas, after the common way of benches or stools, the sun casts rays to their very doors, which warmth and light together, draw them out, at the expence of their provisions and lives together, as is evident from frequent experience, the mildest and clearest winters starving and destroying most bees; when, on the contrary, the coldest and most frozen best secure them. See the article BEE.

APICES, in botany, are the knobs which grow on the tops of the filaments of flowers, containing the male dust, which, when ripe, fecundates the ovary, rendering it prolific, and is the same as antheræ. See **ANTHERÆ**.

APIOS, the knobbed-rooted Virginian liquorice vetch, in botany. See **GLYCINE**.

APIS, in mythology, a famous deity among the Egyptians, represented by an ox, with certain external marks. Into this animal, according to the Egyptians, the soul of the Great Osiris retired, and withdrew itself from the world. He gave this creature the preference, because the ox is the symbol of agriculture, the perfection of which this prince had very much at heart.

The ox apis must have a star in the forehead; that is, a square white mark, the figure of an eagle on his back, a knot under his tongue in the form of a beetle, the hair of his tail double, and a crescent on his right flank; and the cow that bore him must have conceived by a clap of thunder.

As it is difficult to apprehend nature should produce an animal with all these marks, requisite for an apis, we must suppose that the priests took care, by impressing the necessary marks on young calves, to be provided always with one: and if it happened at any time an apis could not immediately be found, and they were obliged to put it off for some time, it was certainly because they were very careful not to be thought guilty of the imposition. But this artifice seems needless; people, on these occasions, voluntarily shut their eyes. When they had found the apis, before they carried him to Memphis, they fed him forty days in a city on the Nile. Women only were permitted to see and wait upon him, and these were obliged to present themselves before the divine ox in an undress. After these forty days, they put him on board a superb vessel, and brought him down the Nile to Memphis, where the priest received him with all imaginable pomp; they were attended by numbers of people, and children were happy who could smell his breath, because they imagined it inspired them with the gift of prophecy.

On his arrival at Memphis, they conducted him to the temple of Osiris, wherein were two magnifi-
cent

cent stalls; one of which was built by Psammeticus, supported by statues, after the manner of the Colossus, twelve cubits high: here he continued almost always shut up, being hardly ever seen but by strangers, to whom he was shewn in a little meadow joining to the temple. If they at any time led him about the city, he was attended by officers to keep off the croud, and accompanied by young children who sung his praises.

APIUM, in botany, the name of an herb called in English parsley. See **PARSLEY**.

APIUM Palustre, smalage. See the article **SMALAGE**.

APIUM Macedonicum. See **BUBON**.

APIUM Pyrenaticum. See **CRITHMUM**.

APOBATERION, a Greek word which signifies a farewell discourse. Among the ancients this term signified any poem, compliment, or speech, which a person, upon quitting his own country, or any foreign land, addressed to his relations, or any friends, amongst whom he had been kindly and hospitably treated. Such is the farewell which Æneas takes of Helenus and of Andromache, in the third book of the *Æneid*.

On the contrary, the first salutation which a person made, upon entering a foreign country, or returning from a journey home, was called epibaterion. See **EPIBATERION**.

APOCALYPSE, the Revelations, a name given to one of the sacred books of the New Testament, written by St. John, and containing revelations concerning several important points of Christianity.

The word is derived from the Greek, *αποκαλυπτω*; I reveal.

It contains twenty-two chapters, which treat of the state of the church from the ascension of Christ till the last judgment, and are as it were the conclusion of the Holy Scriptures. These Revelations were made by St. John the Evangelist, during his exile in the isle of Patmos, whither he was banished by the emperor Domitian. The concatenation of sublime and prophetic ideas which compose the Apocalypse, has ever been a labyrinth in which the brightest geniuses have been lost and bewildered, and the ablest commentators so puzzled and entangled, that it is with the utmost difficulty they could extricate themselves out of it. The many frivolous explanations which they have given of some parts, and the wild reveries they have been thrown into by considering others, is enough to mortify the wit of man, and teach it not to grasp at things so far beyond its comprehension. However, dark and ænigmatical as the greatest part of it is, enough of this prophecy has already been fulfilled to afford sufficient instances of God's divine providence. Many Protestant writers have been of opinion that Rome is frequently alluded to, under

the name of Babylon, the great scarlet whore, seated on seven hills.

There have been great disputes in the first ages of the church whether this book should be esteemed authentic and canonical. Some pretend that it is the work of Cerinthus, who made use of the name of St. John, to give a weight to his wild and fantastic visions. Others say that it was written by a person named John, but not by St. John the Evangelist. But there will be little reason to doubt of its authenticity, if we consider, 1st, That St. John the Evangelist is plainly marked out in these words, "Who bare record of the word of God, and of the testimony of Jesus Christ, and of all things that he saw." 2dly, That it is addressed to the churches of Asia, of which St. John had the government. 3dly, That it is written from the isle of Patmos, whither Irenæus, Eusebius, and all the ancients agree that St. John was banished in the year 95, and returned from thence in the year 98. 4thly, That many writers who lived near the time of the apostles, such as Justin, Irenæus, and Origen, and after them a whole tribe of fathers, attributed it to St. John the Evangelist.

As to its being canonical, though doubted of, as St. Jerom informs us, by many churches in Greece, yet it has been quoted and acknowledged as such by Justin, Irenæus, Origen, Cyprian, Clemens of Alexandria, and all the fathers of the fourth, fifth, and following centuries.

There have been many other books of Revelations. Clemens speaks of the Apocalypse of St. Peter: there is mention made of another of St. Paul: Eusebius speaks of one of Adam: Epiphanius of another of Abraham: Gratian of one of Moses: Jerom of one of the prophet Elias, &c. &c. &c.

APOCLYSMA, in pharmacy, the same with rob. See the article **ROB**.

APOCOPE, the name of a figure in rhetoric, which cuts off a letter or syllable from the end of the word, as *negoti*, for *negotii*, &c.

The word is compounded of the Greek, *απο*, from, and *κοπω*, I cut.

APOCRASIARIUS, in antiquity, an officer who delivered the messages of the emperor. He was afterwards chancellor, and kept the seals.

APOCRUSTICS, in pharmacy, the same with repellents. See **REPELLENTS**.

APOCRYPHA, in its original signification, implies hidden. It is compounded of the Greek *απο*, from, and *κρυπτω*, I hide.

This term apocrypha has been made use of a long time by ecclesiastical writers, to signify books that are doubtful and supposititious, as one may see in St. Jerom, and many other of the fathers Greek and Latin. In this sense it was adopted from the Jews,

Jews, who called only such of their sacred books canonical as had been made public; to those that still remained in their archives, they gave the appellation of apocryphal.

The books that are reckoned apocryphal by our church, are the book of Tobit, Judith, Esther, the book of Wisdom, Jesus the son of Sirach, Baruch the prophet, the song of the Three Children, the history of Susannah, the history of Bel and the Dragon, and the first and second book of Maccabees; as well as those that are esteemed such by the church of Rome, viz. the prayer of Manasseh king of Judah, the third and fourth book of Eddras, St. Barnabas's epistle, the book of Hermos, the addition at the end of Job, and the 151st Psalm.

It is no wonder that the Romish church adopted those books that are regarded by us as apocryphal, into the number of their canonical writings, as they have been so extremely serviceable to them, in supporting, I should have said in giving a gloss to certain tenets and doctrines, for which they could not have found the very shadow of a reason in the other Scriptures. Happily for us we have no occasion for their assistance; and have always looked upon them as apocryphal; as they were not to be found in the catalogues of the canonical books of Scripture that have been given us by Origen, Athanasius, Hilary, Cyril of Jerusalem, and all other orthodox writers, and besides were utterly unknown to the Christian church for some ages. No books but such as have been cited by the earliest writers in support of Christianity, and approved by the council of Laodicea, are regarded by Protestants as of divine authority.

APOCYNUM, dogs-bane, in botany, a genus of plants, whose leaves are produced opposite in pairs on the branches. The flower is monopetalous and campanulated, cut into five parts at the brim. In the bottom of the flower are five corpuscular nectariums, which are oval and surround the germen. The filaments are five in number, and very short, which are topped with oblong erect antheræ. In the center are placed two egg-shaped germen, which support two styles, scarce visible: the germen afterwards becomes a fruit or pod, which opens from the base to the top, inclosing many small compressed seeds having a long pappous down adhering to them.

The down of some sorts of these plants are much used in France for stuffing easy chairs, it being extremely light and elastic: it is also used in quilts, which are very warm; on which account there are several plantations of apocynums raised in the southern parts of that kingdom. All the species of the apocynums abound plentifully with a milky juice.

APODICTICAL Argument, or Syllogism, implies a clear convincing proof of a proposition.

The word is formed from the Greek, ἀποδιδνμι, to demonstrate.

APODOSIS, in rhetoric, the same with axiosis. See **AXIOSIS**.

APODYTERIUM, in the ancient baths, the apartment where persons dressed and undressed.

The word is Greek, ἀποδυτηριον, and derived from ἀποδυειν, to undress.

APOGEE, or **ΑΡΟΓΕΥΜ**, in astronomy, is that point in the orbit of a planet which is at the greatest distance from the earth, according to ancient astronomy, when the earth was placed in the center of the system; but since the moderns have placed the sun in the center, they have changed the terms apogæum and perigæum into aphelion and perihelion for the planets ϵ η δ ζ ξ , but retain them for the sun and moon.

APOGEE of the Moon, is that point of the moon's orbit which is at the greatest distance from the earth; as in Plate XI. fig. 1. where BPAD represents the elliptic orbit of the moon, in which it moves round the earth T, which is placed in the focus of the ellipse. The point A, which is the highest apsis, is called the apogee, or apogæon of the moon.

This apogæum of the moon has an unequal motion, and sometimes moves backwards and sometimes forwards: when it is coincident with the syzygial line, its motion is forwards; but when it cuts that line at right angles, its motion is backwards, and its progress and regress are no ways equal. But when the moon is in her quadratures with the sun, the apogæum goes but slowly forward, or even may stand still, or go backwards; but when the moon comes to be opposite, or conjoined to the sun, the apogæum has a quick motion forward.

The cause and quantities of these motions have been demonstrated by Sir Isaac Newton's Universal Law of Gravitation; namely, that its force is in an inverse ratio of the square of the distance.

But Mr. Clairaut, in a memoir which he read to the academy in the year 1747, pretends to have found by his calculations, that this law of Sir Isaac's would give only one half of the motion of the moon's apogee, which astronomers have discovered by their observations: from whence he concludes, that it was necessary to change this law by adding something to correct its insufficiency. However, this memoir was overturned by a pamphlet written by Mr. Walmley, and the above law again established, and Mr. Clairaut made sensible of the error he had made in his calculations. The method of calculating the motion of the moon's apogee may be seen in the above-mentioned pamphlet, with a demonstration of Machin's Theorem, for the same purpose.

APOGEE of the Equant is the farthest distance from

from the earth, or that point where the circumference of the equant is intersected by the line of the apfides, in the remotest part of the diameter.—The mean apogee of the epicycle is a point where the epicycle is cut above by a right line drawn from its center to the center of the equant, or the point where the epicycle is most remote from the earth.

Apogee of the Sun is the point of the earth's orbit which is the greatest distance from the sun; and consequently the sun's apogee and the earth's aphelion are the same point.

To find the place of the sun's apogee, observe the sun's right ascension, relative to a known star, when it is near the times of its greatest and least velocity. Its longitudes are deduced by seeking the two places, and the times when the sun comes to two points, at the distance of $180^{\circ} 0' 31\frac{1}{2}''$, in the middle of its semi-anomalistic revolution, which is 182 days, 15 hours, 7 minutes, and 1 quarter of a minute. One of these points is the earth's aphelion, and called the sun's apogee, because the earth's motion is attributed to the sun; the other, its perihelion, and called the perigee of the sun.

For example: On the 30th of December 1743, at $0^h 3' 7''$ mean time, the longitude of the sun was found by means of the star Arcturus, to be $8^{\circ} 29' 12\frac{1}{2}''$ in π ; and on the 30th of June 1744, at $0^h 3' 0''$, it was $8^{\circ} 51' 1\frac{1}{2}''$ in ϖ . The difference of these two places is $180^{\circ} 21' 49''$, which exceeds $180^{\circ} 0' 31\frac{1}{2}''$ by $21' 17\frac{1}{2}''$; but the sun describing $57' 12''$ per day, about the 30th of June; therefore, on the 30th of June at $3^h 6' 49''$ in the morning, the sun must have been in $8^{\circ} 29' 43''$ of Cancer, at $180^{\circ} 0' 31\frac{1}{2}''$ from the place where it was on the 30th of December at $0^h 3' 7''$ at night. The interval of time is 182 days, 15 hours, 3 minutes, 42 seconds, which is $3' 33''$ less than the half anomalistic revolution of the sun; therefore, on the 30th of June, at $3^h 6' 49''$ in the morning, the sun had not yet passed through the apogee. Saying then, As $4' 0''$, the difference between the diurnal motions of the sun on the 30th of June and on the 30th of December, is to $57' 12''$, its diurnal motion on the 30th of June; so is $3' 33''$ to $50' 46''$, which added to $3^h 6' 49''$, gives the sun's passage through the apogee, on the 30th of June, at $3^h 37' 55''$ in the morning, at which instant the sun was in $8^{\circ} 31' 35''$ of Cancer; therefore, the sun's apogee, was in 3 signs, 8 degrees, 31 minutes, and 35 seconds. See *De la Caille's Astronomy*.

The annual motion of the sun's apogee is found by accurate observations to be $1' 6''$.

APOLLINARIAN Games, in antiquity, an appellation given to certain theatrical entertainments annually performed in honour of Apollo.

APOLLINARIANS, or **APOLLINARISTS**, a

name given to the followers of Apollinaris, who in the fourth century was bishop of Laodicea. He maintained that Christ had no soul, but that his divinity was to him instead of one. Sometimes he confessed that our Saviour was born a man of the Virgin Mary; and at other times held that he descended in the flesh from heaven, and that his body, being coessential and coeternal with his divinity, ought equally to be worshipped. He published many other absurd and wild doctrines, which his followers improved upon no little, by adding to them a large mixture of the errors of the Manicheans.

APOLLONIA, in antiquity, an annual festival celebrated by the Ægialians, in honour of Apollo.

APOLLONIAN Hyperbola and Parabola. See the articles **HYPERBOLA** and **PARABOLA**.

APOLOGUE, a moral fable, or ingenious kind of fiction, whose end is to mix instruction and entertainment together; of this sort are the fables of Æsop. Some writers have pretended to distinguish between an apologue and a parable; in the former they say only beasts speak, in the latter men; so that the one may be real, the other is necessarily false. But these two words are made use of promiscuously by the best authors.

APOLOGY, a defence or excuse for some person, action, or the like, either by words or writing.

The word is Greek, *απολογία*, and derived from *απολογεσθαι*, to defend or excuse.

APONEUROSIS, in anatomy, the spreading or expansion of a nerve or tendon, in the manner of a membrane.

The word is Greek, and compounded of *απ*, from, and *νευρον*, a nerve.

APONOGETON, in botany, a name given by some to the zannichellia of Linnæus. See **ZANNICHELLIA**.

APOPHYGE, in architecture, the convex part, or ring, of a column, lying either above or below the flat member. It was originally nothing more than the ferril or ring, fixed on the extremity of a wooden pillar to prevent its splitting; and was afterwards imitated in stone.

The word is Greek, and properly signifies *flight*; and hence some architects call it the spring of the column.

APOPHYSIS, in anatomy, a protuberance of a bone, or a part jutting out beyond the rest.

APOLECTIC, something that relates, or belongs to, an apoplexy.

APOPLEXY, among physicians, any disorder which instantaneously deprives a man of life, who a few minutes before was, or at least seemed to be, in perfect health; but it is usually confined to sudden disorders caused by affections of the brain.

The word is derived from the Greek, *αποπληττω*, to strike suddenly.

In an apoplexy the patient is suddenly deprived of the exercise of all the senses, both external and internal, and of voluntary motion, whilst the pulse, which is generally strong, remains, together with a laborious and deep respiration, attended with a considerable elevation of the breast, with a stertor, and the appearance of profound and perpetual sleep.

A multitude of the most accurate observations have made it appear, that this disorder arises from whatever cause is capable of preventing, either totally or in part, the influx of the nervous fluid, secreted in the cerebrum, to the organs of sense and voluntary motion, and the reflux of the same fluid from the abovementioned organs to the common sensory in the brain; whilst the progress, and perhaps the return, of the fluid, supplied by the cerebellum, to and from the heart, and organs of respiration, is preserved in a degree sufficient to support, in some measure, their functions.

All these causes, as observed and delivered by authors, may, for the greater perspicuity, be reduced to classes; in the first of which may be reckoned,

1. The natural make of the body; thus, when the head is naturally large, the neck short, and, as it sometimes happens, consisting only of six vertebrae, whereas there ought to be seven, this structure disposes to an apoplexy, as it favours the congestion of blood and humours in the head. Thus also, if the body is corpulent and fat, the capillary arteries in general will be subject to compression; and, in consequence thereof, a greater quantity of blood and humours will flow into the vessels which convey them to the brain. Thus also a plethoric habit, and a redundancy of pituitous humours in the blood, lay a foundation for the stagnation of the juices, and a subsequent rupture of the vessels in the brain.

2. To the second class belong all those causes which induce such a change in the blood, lymph, and nervous fluid, as to render them incapable of circulating freely through their respective vessels in the brain. Amongst these are,

Polypous concretions in the carotid or vertebral arteries, whether formed originally about the heart, or within the cranium; which are discovered by a palpitation of the heart, an unequal pulse, a vertigo, and temporary loss of sight, often recurring, and which are increased by motion or heat.

3. To the third class belongs whatever compresses the arteries themselves, or the nervous vessels of the brain, so as to prevent a free circulation of their respective fluids through them.

People who are plethoric, that is, full of blood, and bloated with bad humours, are much subject to this species of apoplexy; especially if extraor-

dinary motion or heat increase the velocity of the circulation. Hence it is apparent that the disorder must be promoted in such constitutions by high feeding and spirituous liquors; medicines which are acrid, and excite the motion of the blood, such as cardiacs, volatiles, and emetics; by excessive heat and motion; and by intenseness of thought, especially if long continued, and frequently repeated, because this determines a more copious flux of humours towards the brain.

4. To the fourth class belong all those causes, which, by any means, so dissolve the texture of the arteries, veins, or lymphatic ducts, belonging to the internal part of the cerebrum, as to cause an extravasation of their respective fluids, which then press upon and injure the medullary origin of the nerves of the cerebrum. Such, for example, are an acrimonious serum in hydropic and leucophlegmatic cases; a redundancy of blood in a plethora; an atrabilious acrimony prevalent in melancholy; scorbutic, and arthritic constitutions, which frequently produces an apoplexy, and usually operates betwixt the fortieth and sixtieth years of life. Now, all these may remain latent in the constitution for some time; but, upon being excited by adequate causes, they are frequently productive of a sudden apoplexy; which may be foreseen by comparing the materials subsisting in the constitution with the causes capable of exciting them to action; which are principally violent affections of the mind, and intense studies; to which, perhaps, imprudent and excessive venery may be added.

5. Some sorts of poisons, which are suddenly deleterious, may be ranked in the fifth class; but these may be either reduced to the second, third, or fourth; or may be more properly said to act upon the lungs than the brain. Amongst these are the fumes of mineral sulphurs, of charcoal, and that gas sylvestris, or incoercible spirit, which exhales from vegetable juices during fermentation.

The anatomical inspection of bodies which have died of apoplexies, and the historical observation of such circumstances as occur in the treatment of such cases, furnish us with a knowledge of these causes; and a due reflection upon these naturally leads us to a distribution of them into the preceding classes, which are admirably adapted to the investigation of the best methods of cure.

As to the cure and prevention of an apoplexy, no universal rules can be laid down; for as the predisposing and exciting causes, together with the parts principally affected, are various, the method of relief must also vary; and must be attempted before the disorder grows inveterate, otherwise it will be difficult to do it with success.

If, therefore, an apoplexy, from a glutinous, inert cold cause, is foreseen from the signs above specified, the intentions must be directed, first,

to avert the pressure of the glutinous juices from the head.

Secondly, to attenuate the glutinous viscosity in the brain, and in the whole habit.

The pressure on the vessels of the brain are to be diminished,

First, by a derivation of the humours to other, and these opposite parts.

Secondly, by universal evacuations.

A derivation of the humours is effected by vapours, fomentations, and baths, applied to particular parts, by which it is intended the humours should be invited; by suction with cupping-glasses, by sinapisms and vesicatories, among which cantharides are of great importance, as they both invite the humours to the part where they are applied, and attenuate at the same time; by caustics, issues, setons, and frictions; by ligatures made upon the large veins of the feet, legs, and thighs. To these may be added collutions, gargarisms, and masticatories, which excite a discharge of saliva, and apoplegmatisms applied to the mouth, fauces, and nose. *Baerhaave.*

APOSIOPESES, in rhetoric, implies the suppressing, or omitting to relate part of the subject.

The word is Greek, and derived from *αποσιωπω*, to keep silence.

APOSTACY, the act of abandoning the true religion.

APOSTHUME, in surgery, the same with abscess. See the article ABSCESS.

APOSTIL, a marginal note, or remark in the margin of a work.

APOSTLE, a messenger sent by some person on a business of importance; and hence the word is applied by way of eminence to imply one of the twelve disciples commissioned by Christ to preach the Gospel.

The word is formed from the Greek, *αποστολ*, and derived from *αποστέλλω*, to send on a message.

There are various conjectures with regard to the reason which induced our Saviour to make choice of twelve apostles; but the most probable is, that he did it in allusion to the twelve patriarchs, as the founders of their several tribes; or to the twelve chief heads or rulers of those tribes, of which the body of the Jewish nation consisted.

APOSTOLIC, or APOSTOLICAL, something connected with, or derived from, the apostles.

APOSTOLICS, a name which two sects of Christians took upon themselves formerly, under pretence that they imitated the manners and conduct of the apostles. The first of the Apostolics, otherwise called Apotactiques, sprang up in the third century, and professed abstinence from marriage, from wine, and from flesh. The others arose in the twelfth century, and likewise con-

demned marriage, but allowed the use of concubines: they would not admit of baptism, and in many respects imitated the errors of the Manicheans.

APOSTROPHE, a figure in rhetoric, when an orator abruptly breaks off his discourse, and addresses himself immediately to any person, quality, or thing, animate or inanimate, as if it was present, and was capable of being affected by him. Such, for instance, is that passage in the fifteenth chapter of the Corinthians, where St. Paul, after he had shewn that this corruptible body should put on incorruption, and this mortal be clothed in immortality, calls out, with an air of triumph, *O Death, where is thy sting? O Grave, where is thy victory?*

If this figure is introduced with propriety, it has a most happy effect; as it takes off the languor of a dull narration, and converts a dry and cold description into life and action. But it ought to be made use of very sparingly; for the thread of an orator's discourse should never be broken off, to turn the eyes of his audience on objects that are either trifling of themselves, or made so by being introduced, when they are foreign to the business in hand.

The word is compounded of the Greek, *απο*, from, and *στροφή*, to turn.

APOSTROPHE, in grammar, signifies a mark placed over a word, to shew that there is a letter, or syllable wanting, as *mourn'd*, for *mourned*, and *deum*, for *deorum*.

APOTACTITES, in ecclesiastical history, the same with apostolics. See APOSTOLICS.

APOTHECARY, a person who practises the art of pharmacy.

The word is formed from the Greek, *αποθήκη*, a shop.

This is a very genteel business, and has been in very great vogue of late years, there being, as has been computed, upwards of 1000 in and about London.

APOTHEOSIS, was a kind of consecration, or ceremony, made use of by the heathens, by which they inserted any of their emperors, or great men, into the number of the gods.

The word is compounded of the Greek, *απο*, and *θε*, a god.

It is of longer standing amongst the Romans than since the time of Augustus, to which its origin has generally been ascribed: for during the republican state of Rome, there were instituted in Greece and Asia Minor, feasts and games in honour of the proconsuls sent from Rome; and priests and sacrifices were appointed, and temples and altars built, where they were worshipped as divinities. From thence it was adopted, as a most fulsome and impious kind of flattery, to pay court to the emperors. Temples were built to Augustus, while

while he was yet alive; and when he was dead, he was solemnly and ceremoniously ranked among their gods; which passed at length into a custom, and was conferred upon all his successors.

As soon as the emperor was dead, the whole city put on mourning; the body was buried in the usual manner, but with amazing pomp and magnificence. In the vestibule of the palace, on a bed of ivory, covered with cloth of gold, was laid a figure of wax; which exactly resembled the deceased, with a pale and languid look, as when he was sick. The senate in mourning weeds were ranged along the left side of the bed, during the greatest part of the day; and on the right, were the matrons, and young ladies of the first quality, dressed in flowing robes of white, without collars or bracelets. This lasted for seven days successively, during which the physicians approached the bed from time to time to visit the patient; and always made their report, with solemn despairing faces, that he grew worse and worse, and there were no hopes. Herodian, from whom this account is taken, does not tell us whether the physicians *prescribed* or not; in all probability they did, as otherwise they could not be entitled to fees.

At the end of seven days this waxen image died; and was carried on the shoulders of the Roman knights, and young senators, along with the bed of state, through the Via Sacra to the Old Forum, where was erected a painted alcove of wood. Upon this alcove were a row of pillars, adorned with ivory and gold, on which they placed the image. The new emperor, the magistrates, and ladies sat down here, while two choirs of music sang the praises of the dead; and after his successor had spoken his eulogium, the body was carried out of the city into the Campus Martius, where a funeral pile was prepared. It was composed of wood in the form of a square pavilion, four or five stories high, decreasing gradually to the top like a pyramid. The inside was filled with combustibles; and the outside adorned with cloth of gold, inlaid with ivory, and rich paintings. Every story composed a portico, supported by columns; and on the top of the edifice was usually placed, in a gilded chariot, an effigy of the deceased emperor. The new emperor, with a torch in his hand, set fire to the pile, and the chief magistrates doing the same on all sides, the flame mounted soon to the summit, from which it affrighted an eagle, or a peacock, that flying in the air carried with it, according to the notions of the people, the soul of the emperor to heaven; from which moment altars were built to him, and he was worshipped as a god.

The apotheosis has been conferred on the favourites of princes, or their mistresses, &c. but in general, this honour was never bestowed in Greece,

but at the command of an oracle, nor in Rome, but by a decree of the senate.

It was thus the ancients deified their princes, their heroes, the inventors of arts; and we read in Eusebius, Tertullian, and Chrysostom, that upon the fame of the miracles done by Christ, Tiberius propoed to the senate of Rome, to rank him amongst the gods: but the proposal was rejected, because it was contrary to the laws to introduce into Rome the worship of strange gods: by this name they distinguished the gods of all other nations, except the Greeks, whom alone they did not look upon as barbarous.

The vast number of persons to whom the honours of the apotheosis were paid, rendered the ceremony at last vile and contemptible. In Juvenal, Atlas, fatigued with the weight of so many new gods, groans desperately, and declares that he is ready to sink under the burden of the heavens: and the emperor Vespasian, who was naturally fond of raillery, in the very agonies of death cried out to those around him, "I find that "I am beginning to grow a god every moment."

APOTOME, in geometry, is the difference between two incommensurable quantities or lines; thus the line DE, (Plate X. fig. 8.) is the apotome of AC, and CD. Eucl. x. 74.—If we suppose AD equal to a , and $AC = b$ then will their apotome be $a - \sqrt{b}$; or in numbers, $2 - \sqrt{3}$. Hence also the difference between the side BD = 2, (Plate X. fig. 7.) of an equilateral triangle ABD, and the perpendicular $AC = \sqrt{3}$, is an apotome; viz. $= 2 - \sqrt{3}$; and universally if BD, (fig. 9.) be a semi-parabola, whose axis is AB, & *latus rectum* be = 1, and if BC be a tangent to the vertex at B, and this be divided into the parts $Ba = 2$, $Bb = 3$, $Bc = 4$, $Bd = 5$, &c. and perpendiculars a_1, b_1, c_1, d_1 , these will be from the nature of the curve $\sqrt{2}, \sqrt{3}, \sqrt{4}, \sqrt{5}$, &c. respectively, and therefore half $Ba (= 1) - a_1$ will be $1 - \sqrt{2}$; $Ba - b_1$ will be $2 - \sqrt{3}$; $Bb - c_1$ will be $3 - \sqrt{4}$; and $Bc - d_1$ is $4 - \sqrt{5}$; &c. hence by this means we have an infinite series of different apotomes.

Euclid, in 10 lib. and third definition after prop. 85. distinguishes apotomes into first, second, third, fourth, fifth, and sixth; and in the propositions immediately following, shews the method of finding them. The first is when there are two numbers such, that the greatest is a rational one, and the difference between their squares is a square number. A second apotome is when the least number is rational, and the square root of the difference of the squares of the two numbers has a ratio in numbers to the greatest number.

A third apotome is when the two numbers are both irrational, and the square root of the difference of their squares has a ratio in numbers to the greatest number.

A fourth apotome is when the greatest number is rational, and the square root of the difference of the squares of the two numbers, has not a ratio to that.

A fifth apotome is when the least number is rational, and the square root of the difference of the squares of the two numbers, has not a ratio in numbers to the greatest number.

A sixth apotome is when both the numbers are irrational, and the square root of the difference of their squares, has not a ratio in numbers to the greatest number.

The doctrine of apotomes, as laid down by Euclid in his tenth book, is a very curious subject, and worthy to be perused and improved by all those who would lay down geometrical elements, from whence might be produced the possibility or impossibility of the quadratures of curve-lineal figures, and perhaps lineal solutions of Diophantus's Problems, and others of a similar kind; though all the use one would think Euclid made of this book was only to shew the nature of the five regular bodies, which by Plato and his sect were held in great esteem.

APOTOME, in the *Theory of Music*, by some writers, is the difference between a greater and lesser semi-tone, being expressed by the ratio of 128 to 125.

APOZEM, in pharmacy, the same with decoction. See DECOCTION.

APPANAGE. See the article APANAGE.

APPARATOR. See APPARITOR.

APPARATUS, a term used to denote a complete set of instruments, or other utensils, belonging to any artist or machine; thus we say a surgeon's apparatus, a chemist's apparatus; the apparatus of the air-pump, microscope, &c.

APPARENT, in a general sense, is something that is visible to the eyes, or obvious to the understanding.

APPARENT *Altitude*. See the article ALTITUDE.

APPARENT *Conjunction*, in astronomy. See CONJUNCTION *Apparent*.

APPARENT *Diameter*, in astronomy, is the angle under which we see any of the planets, as thus; Let S represent the planet Saturn with his ring, (Plate XI. fig. 2.) E, the eye of an observer on the earth, from which draw EA, and EB; then the planet Saturn appears under the angle AEB, which angle is called the apparent diameter of Saturn.

There are various ways of measuring the apparent diameters of the planets, but the best and most approved way is by micrometers. See a description of the different micrometers under the article MICROMETER, with the method of using them, &c.

The diameter of the sun, or full moon, may be very accurately measured by the altitude of the upper and lower limb, taken with two quadrants by two persons at the same instant of time; or by one person, with a quadrant fixed in the plane of the meridian, if he is experienced in observation, has a good eye, and expert in handling an instrument; for the sun will not sensibly vary his altitude on the meridian in the time a good observer will take the altitude of both limbs; consequently the difference of the altitudes is the diameter.

Likewise the horizontal diameter of the sun, moon, &c. may be accurately observed by a transit instrument, and good regulator, by taking the difference of the time of passage over the meridian of the first and last limbs, which difference is the diameter in time when the sun is in the equator, and may be turned very easily into parts of a degree or circle. But if the sun is in the same parallel of the equator, the time must be reduced to the equator. For the diameter, &c. of each planet, see under the name of each particular planet.

APPARENT *Distance*, is that distance which we imagine any object to be seen afar off from us, which mostly differs very much from the true; for instance, in viewing the heavenly bodies, they apparently seem to be at equal distances from us, though it is well known they differ many thousands of miles. Likewise, when we view remote objects on the earth, which stand separate from other objects, we find that the apparent difference of their apparent distance from us seldom bears any proportion to the true, it being sometimes more and sometimes less.

APPARENT *Horizon*. See HORIZON.

APPARENT *Figure*, is that figure, or shape, which any object appears under when viewed at a distance, which is found generally very different from the true figure. Thus, a straight line at a distance may appear a point; the arch of a circle, a straight line; a solid, a surface; a surface, a line; a square, or oblong, a trapezium, or even a triangle; a circle, an ellipse; a sphere, a circle; and each will vary according to their different positions, directions, or inclinations.

APPARENT *Magnitude of an Object*, is the magnitude it appears to be of to the eye, and is measured by the optic angle it appears under. Thus, Let AB, (Plate XI. fig. 3.) be an object viewed directly by the eye QR: from each extremity A and B, draw the lines AN and BM intersecting each other in the crystalline humour in I; bisect AB in K, and draw IK: then is the angle AIK half the optic angle AIB, which is the measure of the apparent magnitude, or length of the object AB.

Diverse objects, AB, CD, EF, whose real magnitudes are very unequal, may be situated at such distances from the eye, as to have their apparent magnitudes all equal. For if they are so

situated, that the rays AN, BM, shall touch the extremities of each, they will all then appear under the same optic angle AIK, which is equal to ANIM, which determines the magnitude of the image MN, in the bottom of the eye, the same for them all; and therefore they must all appear of an equal magnitude.

Objects situated at different distances, direct to the eye, whose apparent magnitudes are equal, are to each other as their distances from the eye directly. Let the objects be AB and CD; then because the right-angled triangles CIL and AIK are similar, it will be as IK: IL:: AK: CL; but AK is half AB, CL half CD; therefore it will be, as IK: IL:: AB: CD.

Objects of equal magnitudes, situated directly before the eye at unequal distances, will appear unequal. For let AB and GH be two objects directly before the eye, at different distances, IK, and IS; draw the lines GP and HO crossing each other in I; then is the optic angle GIH manifestly greater than the angle AIB, and the image OP, made by the former, greater than the image MN, made by the latter: therefore the object GH is apparently greater than the object AH, though it is but equal to it.

Equal objects situated directly before the eye at unequal distances, have their apparent magnitudes reciprocally proportional to their distances. For let AB, GH, be two equal objects at unequal distances IK, IS, from the eye; produce IG and IH till they intersect AB, each way, produced in T and V. Then will TV be the apparent magnitude of GH, at the distance IK: since the triangles ISG and IKT are similar, we shall have IS: IK:: SG: KT; but SG is equal to AK; therefore it will be IS: IK:: AK: KT.

From what has been said, it appears that there is no standard of the true magnitude of things. All that we can be sensible of is, the proportion of magnitude; and yet, notwithstanding the sensible magnitude of things is ever mutable, and varies in proportion to the distance, we scarcely ever judge any thing to be so great or small as it appears to be, or that there is so great a disparity in the visible magnitude of two equal bodies at different distances from us.

Thus, for instance, suppose two men of six feet stature each, stand directly before a person, one at the distance of one rod, and the other at the distance of an hundred. We should, indeed, observe a difference in their apparent bigness, but should hardly think one appeared an hundred times greater or less than the other; or that one appeared six feet high, the other not three-fourths of an inch.

But this happens from our prenotions, or judgment that we have beforehand formed of things: we know the proportions of magnitudes in general, and are apt to retain the ideas of things we know

to be true; and to prefer them to others, which are presented by our senses, and exist there only, and not in the true relations of things.

APPARENT Motion. See MOTION.

APPARENT Place, in astronomy, is that point on the surface of a sphere, which is determined by a line drawn from the eye to the center of the planet, or other object in the heavens.

APPARENT Place of any Object, in optics, is that place wherein it appears, when seen through one or more glasses. See LENS.

APPARENT Place of the Image of an Object, in catoptrics, is that place which the image of an object appears to be in, when made by the reflection of a speculum.

APPARENT Time. See TIME.

APPARITION, in a general sense, implies simply the appearance of any object.

APPARITION, in astronomy, is when the planets, stars, or any other heavenly object becomes visible, which before was below the horizon; thus the heliacal rising is rather an apparition than a rising.

Circle of perpetual APPARITION, in astronomy, is a great circle of the sphere, whose plane is perpendicular to a line drawn from the center of the sun to the earth; the enlightened part of the hemisphere is bounded by this circle in the different points of its orbit. But in geography it is a small circle of the sphere, described about the pole as a center, touching the southern part of the horizon in south latitude, and the northern in north latitude. All stars in this circle never set, but are constantly above the horizon; thus the star α , in Lyre, makes this circle by its diurnal motion to the latitude at Greenwich nearly.

APPARITOR, among the Romans, a general term to comprehend all attendants of judges and magistrates appointed to receive and execute their orders. Apparitor, with us, is a messenger that serves the process of a spiritual court, or a beadle in a university, who carries the mace.

APPAUMÉE, in heraldry, denotes one hand extended with the full palm appearing, and the thumb and fingers at full length.

APPEAL, in law, the removal of a cause from an inferior to a superior court or judge, when a person thinks himself aggrieved by the sentence of the inferior judge. Appeals lie from all the ordinary courts of justice to the house of lords. In ecclesiastical cases, if an appeal is brought before a bishop, it may be removed to the archbishop; if before an archdeacon, to the court of arches; and thence to the archbishop; and from the archbishop's court to the king in chancery.

APPEAL, in common law, is taken for the accusation of a murderer by a person who had interest in the party killed, or of a felon by an accomplice. It is prosecuted either by writ or by bill.

By writ, when a writ is purchased out of the chancery by one person against another, commanding him to appeal some third person of felony, and to find pledges for doing it effectually; by bill, when the person himself gives in his accusation in writing, offering to undergo the burden of appealing the person therein named.

APPEARANCE, in a general sense, the exterior surface of a thing, or that which immediately strikes the senses.

APPEARANCE, in law, signifies a defendant's filing a common or special bail, on any process issued out of a court of judicature. In actions by original, appearances are entered with the filazer of the county; and by bill, with the prothonotary.

APPEARANCE, in astronomy, is the same with phenomena and phases, which are more commonly made use of. See **PHENOMENA** and **PHASES**.

Direct APPEARANCE, in optics, is when we view any object by direct rays, without refraction or reflection.

APPEARANCE, in perspective, is the projection of any figure on the perspective plane. See **PERSPECTIVE**.

APPELLANT, in a general sense, one who appeals. See the article **APPEAL**.

APPELLANTS, signify in church history, those of the Roman catholic clergy who appeal from the bull-*Unigenitus*, given by Clement the Xth. to a general council.

APPELLATIVE, in grammar, is a name that is applicable to any genus, or species, in contradistinction to proper names that belong to individuals: thus, the words horse, tree, ass, &c. are appellatives; Richard, Thomas, Henry, are proper names.

APPELLEE, among lawyers, the person against whom an appeal is brought. See the article **APPEAL**.

APPENDANT, in law, any thing that is inheritable belonging to some more worthy inheritance; as an advowson, common, or court, may be appendant to a manor, land to an office, &c. but land cannot be appendant to land, for both are corporeal inheritances, and one thing corporeal cannot be appendant to another.

APPENDICULAR *Vermiformis*, in anatomy, a name by which some call the cæcum. See the article **COECUM**.

APPENDIX, in literature, a treatise added at the end of a work, to render it more complete. See the article **SUPPLEMENT**.

APPENDIX, in anatomy, the same with epiphyses. See **EPIPHYSIS**.

APPETITE, *Appetitus*, in a general sense, the desire of enjoying some object, supposed to be conducive to our happiness. When this inclination is guided by reason, and proportioned to the in-

trinsic value of the object, it is called rational appetite; as, on the other hand, it is denominated sensitive appetite, when we have only a blind propensity to a thing, without determinate ideas of the good qualities for which we desire it.

APPETITE, in medicine, a certain painful or uneasy sensation, always accompanied with a desire to eat or drink.

An excessive appetite is called by physicians bulimy, or fames canina; a defect or loss of it, anorexy; and that after things improper for food, pica. See the articles **BULIMY**, **ANOREXY**, &c.

APPLE, a well known fruit of a roundish form, consisting of a rind, or skin, a pulp, or parenchyma, branchery, or seed vessels, and a core. The rind or skin is only a dilatation of the outward rind of the bark of the branch, which produces the fruit; the pulp, although very tender and fine flavoured, is likewise a dilatation or superabundance of the inner part of the bark: this is discoverable not only from the visible continuation of the bark from the one, through the stalk to the other, but also from the bladders which both are composed of, and common to each, with this difference, that whereas in the bark the vesiculæ are globular and small, in the pulp they are oblong, and very large, but all uniformly stretched out by the arching of the vessels, from the core towards the circumference of the fruit; the branchery or vessels are only ramifications of the woody part of the branch, sent throughout all the parts of the pulp, the greater branches being made to communicate with each other by inoculations of the less. The main branches are commonly twenty, ten of which are distributed through the parenchyma, most of which direct themselves towards the stool of the flower; the other ten, running in a more direct line, meet at the stool of the former, and are there inoculated with them: to these branches are joined the coats of the kernels. Most of these branches were before extended beyond the fruit, and inserted into the flower for the proper growth thereof; but as the fruit afterward grew larger, and intercepted the aliment before sent to the flower, which being starved, and falling off, the service of the said branches become entirely appropriated to the fruit, fifteen to the pulp, and five to the seed. The apple core is originally from the pith of the branch, the sap of which finding room to diffuse itself in the parenchyma, quits the pith, and hardens into the substance that it appears in.

Amongst all the great variety of fruits growing in England, there is none so universal as the apple, for be the land of a hot and dry, or wet and cold nature, one or other of the sorts (of which there are many) will produce fruit, and where the land is good in its kind, in very great quantities. The excellency of the liquor, called cyder, which

is extracted from this fruit, is a sufficient encouragement for its propagation, exclusive of its profitable uses at table, in the kitchen, &c. There are various kinds of apples, some of which ripen in the summer months, and have their peculiar names to distinguish them by, as the Margaret apple, the junneting, the codling, the summer pearmain, &c. Other sorts, which are eatable in winter, as the golden pipin, nonpareil, winter pearmain, and divers others, which are of use either for the table, pastry, &c. Also several sorts which are most preferred for making cyder, the chief of which are, the red-streak, Devonshire wilding, the whitfour, Herefordshire under leaf, John apple, everlasting hanger, gennet moyle, and several others.

Although the trees which produce this fruit are so very common in England, it is not a proof that the apple-tree is a native of this island; for according to the observation of Sir William Temple, it appears that soon after the conquest of Africa, Greece, Asia Minor, and Syria, by the Romans, there were brought into Italy divers sorts of mala, which we call apples, and from thence sent into other parts of Europe, and propagated as other fruits; the crab-apple, perhaps, may be excepted, though not with any certainty.

All the different sorts of apples are propagated by grafting, or inoculation, though the latter operation is seldom practised. The stocks which they are grafted on must be of the same kind, for if they are grafted on the pear or quince stock (which, according to the system of Linnaeus, are of the same genera) they will not succeed. There are three sorts of stocks used in the nursery gardens, upon which apples are grafted; one sort called free stocks, which are raised from the kernels of any kind of apples, which without distinction are called crabs; but those that are most preferable is from the crab-apple, of which verjuice is made, it being reckoned more hardy, and consequently better enabled to endure the rigour of very severe winters: the stock, called the Dutch creeper, is made use of in grafting this fruit, to check the luxuriancy of growth, therefore designed for such trees that are intended to be planted as dwarfs or espaliers: the third sort is called the paradise-stock, which is a low shrub; if apples are grafted on this stock, they will produce fruit the second or third year. It was formerly a practice amongst gardeners to plant small apple-trees, grafted on paradise-stocks, in large flower pots or tubs, whereby they produced fruit very plentifully, being kept in small open heads or dwarfs, which were then esteemed great embellishments to the entrances of parterres, cabinets, &c. but in the modern practice of gardening, is now in disuse.

All the orchard apples generally agree in the common property of cooling and allaying thirst, though they somewhat differ in degree; as they are

more or less acid or austere. Those are most wholesome which most abound with this last property, because it maintains the due tenacity of the fibres, and prevents their corrupting with the animal juices. This fruit makes a very good part of our food in summer time, when the heat evaporates so much of the animal moisture, as would be insupportable to the constitution, were it not frequently refreshed with the grateful sensations which such coolers produce. For a farther account of propagating the apple, see the articles *Stock* and *Grafting*.

APPLE-TREE. See *MALUS*.

APPLES of *Love*. See *LYCOPERSICON*.

APPLICATE, or *APPLICATE Ordinates*, in geometry, are parallel lines, as *aa*, *bb*, (Plate XL fig. 4.) terminating in a curve, and bisected by a diameter, as *AB*; the half of these, as *ac*, and *bd*, is properly the semi-ordinate, though commonly called ordinate. See *CURVE*, *HYPERBOLA*, *PARABOLA*, *ELLIPSIS*.

APPLICATION, in a general sense, implies the laying two things together, in order to discover their agreement.

APPLICATION of one Science to another, signifies the use we make of applying the principles and truths belonging to one science, to complete or advance another.

APPLICATION of *Algebra* to *Geometry*, implies the solving geometrical problems by the assistance of algebra.

As the line, the surface, and the solid, objects of geometry are commensurable magnitudes, it is very natural to think that as algebra and analysis were wholly employed in the calculation of magnitudes, and discovering unknown quantities from proper data, they might be applied with very great advantage to geometry. But however natural and easy this application may appear, Des Cartes was the first that ever knew it, though algebra had been very greatly improved by several persons, especially Vieta.

Des Cartes first taught us to express the nature of curves by equations, to resolve geometrical problems by these curves, and, in short, to demonstrate theorems in geometry by the help of algebraical calculation, when it would be too laborious to demonstrate them by the common methods. See the articles *CURVE* and *Construction of EQUATIONS*.

APPLICATION of *Geometry* to *Algebra*.—The application of geometry to algebra is not so common as the application of algebra to geometry, but sometimes takes place: for as we represent geometrical lines by equations, so we may represent numerical quantities, expressed by algebraical symbols, by geometrical lines; and by this means sometimes discover a more easy method of demonstration and solution.

APPLICATION of Geometry and Algebra to Mechanics.—This is founded on the same principles as the application of algebra to geometry. It consists chiefly in representing the curves which bodies describe in their motion by equations, in determining the equation between the spaces which bodies generate, (when acted upon by any powers whatever) and the time they take to pass through these spaces, &c. We cannot indeed compare two things of a different nature together, such as space and time; but we may compare the proportion of time with the parts of space passed over. Time in its nature flows uniformly, and mechanics imply the same uniformity.

Further, without knowing time in itself, and having any exact measure of it, we cannot represent it more clearly, with respect to its parts, than by the parts of an infinite right line. Now the proportion between the parts of such a body, moved in whatever manner, may always be expressed by an equation. Let us suppose a curve, the abscissa of which represent the portions of time past since the beginning of the motion, the corresponding ordinates denoting the spaces passed through during these portions of time. The equation of this curve will express, not only the proportion of the time to the space, but, if we may speak so, the proportion of the proportion that the parts of time have to their unity, to that which the parts of space passed through have to theirs; for the equation of a curve may be considered either as expressing the proportion of the ordinates to the abscissa, or as the equation between the proportion that the ordinates have to their unity, and that which the corresponding abscissa have to theirs.

It is evident then, that by the bare application of geometry and calculation, we may account for the general properties of motion, varied by any law whatever, without the help of any other principle. In the article *ACCELERATED Motion*, may be seen an example of geometry applied to mechanism; the time of the descent of a gravitating body is there represented by the perpendicular of a triangle, the velocity by the base, and the spaces passed through by the area of the parts of the triangle.

APPLICATION of Geometry and Algebra to Physics. This we owe to Sir Isaac Newton, as we owe the application of algebra to geometry to Des Cartes, and it is founded on the same principles. The properties of bodies in general have between each other certain proportions, which we may compare with each other, more or less distinguishable; and these we can discover by geometry or algebra. On this are founded all the physico-mathematical sciences. One single observation or experiment often demonstrates a whole science. As for example: The bare knowledge of this, that the angle

of incidence is equal to the angle of reflexion, which is known to be true, contains the whole science of catoptrics. This principle of the equality of angles being once admitted, catoptrics becomes a science purely geometrical, because it is reduced to comparing angles with given lines of position. The thing is the same in many other cases. By the help of geometry and algebra, we can in general determine the power of one effect, which depends on another better known. This science, therefore, is almost always necessary to compare and examine the facts: experiments discover to us. It must be owned, however, that every subject of physics is not equally capable of the application of geometry. Several experiments admit of no calculation at all; such are those of the magnet, electricity, and many others; in these cases we must forbear applying to geometry. Many, however, are apt to run into this fault, by advancing hypotheses on experiments, and proceeding to calculations according to these hypotheses; but these calculations ought no farther to be regarded, than as the hypotheses on which they are supported are conformable to nature; and, therefore, observations ought to confirm them, which unfortunately sometimes does not happen. Besides, supposing the hypotheses true, they are not always sufficient. If there be an effect produced by a great number of circumstances owing to several causes, which act all together, and we content ourselves with considering some of these causes only, which, being more simple, can be calculated more easily; we may gain a partial effect of these causes; but it will be very different from the total effect which would result from uniting all the causes.

APPLICATION of a geometrical Method in Metaphysics.—Geometry has been sometimes abused in physics by applying the calculation of the properties of bodies to arbitrary hypotheses. A geometrical method has also been misapplied in sciences, which in their own nature submit to no calculation, we mean the method only, not the science. Several metaphysical writers, who have published certain truths, have yet, copying after the manner of geometers, ridiculously enough swelled their page with the pompous words axiom, theorem, corollary, &c.

The authors of these works certainly imagined that these words, by some secret charm, composed the essence of a demonstration; and that by writing at the end of a proposition, that it might be demonstrated, they should make that demonstrable which was not really so. Geometry does not owe its certainty to this method, but to the evidence and simplicity of its object: and though a treatise on geometry, when divested of its ordinary terms, may be very good; yet a treatise on metaphysics may be often very bad, by the affectation of fol-

lowing a geometrical method. We ought even to distrust this class of writers: for the generality of their pretended demonstrations are only founded upon an abuse of words.

Those who have considered these things, know how common and easy the abuse of words is, especially in metaphysical subjects. It is in this particular the schoolmen have excelled; and it is pity they made no better use of their sagacity.

APPLICATION of Metaphysics to Geometry.—Metaphysics are sometimes misapplied in geometry, as well as geometry in metaphysics proper to itself, which is certain and incontestable; because the geometrical propositions which result from it, afford an evidence which demands our assent. But as mathematical certainty arises from the simplicity of its objects, its metaphysics too must be extremely simple and clear; must always be capable of being reduced to perfect ideas, without any obscurity. In short, how can the consequences of any thing be certain and evident, if the principles are not so? Yet some authors have thought themselves able to introduce into geometry a kind of metaphysics, often obscure; and, what is still worse, have affected to demonstrate, metaphysically, truths which have been already established on other principles; this surely was the way to render those truths doubtful, if they could possibly be so. The new geometry has principally occasioned this false method. By considering parts infinitely small as real quantities, and admitting some of these to be greater and some less, they have acknowledged an infinity of small particles of different classes; and looked on them as real somethings, instead of endeavouring to reduce these suppositions and calculations to simple ideas.

Another abuse of metaphysics in geometry consists in confining metaphysics to geometrical demonstrations. Admitting even the metaphysical principles we set out upon to be certain and evident, there are scarce any geometrical theorems that can be accurately demonstrated by their help alone; they almost always require lines and calculations: this manner of demonstration is very material, because it is in short the only sure and certain method; since with our pens, not metaphysical reasonings, we can make combinations and certain calculations.

This latter kind of metaphysics, which we have been speaking of, is however useful to a certain degree, provided we do not confine ourselves too much: it makes us carefully examine the principles of discoveries; it furnishes us with lights; it points out to us the road; but we are not sure of being right, if we may be allowed the expression, without the staff of calculation to point out the proper objects which we before saw confusedly.

One would think great geometers might always be excellent metaphysicians; at least in the

objects of their science. This is not, however, always the case: some geometers are like people who possess a sense of seeing, contrary to that of feeling; this proves yet more how necessary calculation is in geometrical truths. One may venture to affirm, that the geometer who is a bad metaphysician in the objects he applies himself to, will in others be intolerable: though geometry, whose object is the mensuration of body and matter, may in some cases be applied to thought.

APPLICATION of one Thing to another, is a term made use of to denote the service the first is of to understand or bring the second to perfection. Thus the application of the cycloid to pendulums signifies the use made of the cycloid to bring pendulums to perfection.

APPOGIATURA, in music, implies a small note inserted by practical musicians between two others at some distance.

APPORTIONMENT, in law, the division of a rent into parts, in the same manner as the land out of which it issues is divided.

APPOSITION, in grammar, is a name given to a particular kind of construction, which is called in Greek *επάρησις*: it consists in putting two, or more substantives in the same case, without any copulative to join them. Thus in Virgil,

*Formosum Pastor Corydon ardebat Alexim,
Delicias Domini.*

APPOSITION, among naturalists, is the same with *juxta-position*. See the article *Juxta-Position*.

APPRAISING, the act of valuing or setting a price upon goods.

APPREHENSION, in logic, the first or most simple act of the mind, whereby it perceives or is conscious of some idea. See the article *PERCEPTION*.

APPREHENSION, in law, implies the seizing a criminal in order to bring him to justice.

APPRENTICE, a young person bound by indenture to some tradesman, in order to be instructed in his mystery or trade.

APPROACH, the acceding or advancing of two objects towards each other.

APPROACHES, in fortification, are trenches thrown up and carried on in a zigzag manner by the besiegers, in order to get nearer the fortress, without being exposed to the fire of the enemy's cannon; these trenches are connected by parallels, or lines of communication.

APPROACHING, in gardening; see the article *GRAFTING by Approach*.

APPROPRIATION, the annexing a benefice to the proper and perpetual use of a religious house, bishopric, college, &c.

APPROVER, in law, implies a person, who, having been concerned in committing a felony, accuses one or more of his accomplices.

APPROXIMATION, in arithmetic, and algebra, is the method of approaching nearer and nearer to truth, without being able to gain it exactly. There are several methods of approximation laid down by Dr. Wallis, Halley, Ralston, Ward, Maclaurin, Simpson, &c. which are all nothing more than a series continually converging or approaching nearer to the quantity sought, according to the nature of the series. See **SERIES**, &c.

APPUI, in the menage, implies the sense of the action of the bridle in the horseman's hand.

APPULSE, in astronomy, is the approach of a planet to the sun, or any fixt star, and is a step towards a transit, conjunction, occultation, eclipse, &c.

The appulse of the moon to fixt stars, since their places have been accurately settled by observation, and the moon's theory corrected, by that most accurate astronomer Dr. Bradley, whose death, can never be too much regretted by the astronomers of this nation, is deemed one of the best methods for determining the longitude at sea. The computation at present is too prolix and difficult for sailors, nay, even for most of our learned and theoretical astronomers to put in practice; and though they may lay down rules, and call them short, yet they have not hitherto been able to persuade the practical navigators that they really are so. However, there is now a scheme before the learned and honourable commissioners of longitude, (given in by Mr. George Witchell) for intirely reducing this laborious and difficult computation; and we are apprehensive that this will be the last improvement of the kind, for this gentleman seldom puts any astronomical problem out of his hands, without giving it the finishing stroke; and if he does succeed, as a few months time will determine, we may reckon the appulse of the moon and fixt stars second to Mr. Harrison's time-keeper, with regard to finding the longitude at sea.

APPURTENANCES, in common law, signify whatever things belong to another thing as principal: as hamlets, fisheries, &c. to a manor; seats in a church to houses, &c.

APRICOT, *Armeniaca Malus*, in botany, a genus of fruit-trees, classed by Linnæus with the prunus, or plum. Although the generative parts of the flowers agree according to his system of botany, yet as there is a very material difference not only in the plant and foliage, but also in the taste and form of the fruit, it may therefore be necessary in this work to mention them distinctly. It is said, the apricot (commonly so called) is a native of Epirus, or Epire, a province of Greece, and from thence called *Malus Epirotica*, from whence the English name apricot may be derived, though, more commonly called by the Romans

Malus Armeniaca, which implies its being originally brought from Armenia in Asia; however, there can be little doubt but that the Romans first introduced it into Italy, and from thence to other European countries. This tree, in England, grows to a tolerable size, producing roundish acuminate leaves serrated at their edges, and placed alternately on free-growing branches, though on the cursons, or spurs, they grow five or six together in a bunch. The flowers, which are rosaceous, (see the article **PRUNUS** for their generical characters) appear early in the spring before the leaves, and are succeeded by a well-known fleshy succulent fruit. In England there are seven sorts or varieties cultivated, which are, 1. The masculine apricot, which is soonest ripe, and of a small roundish form. 2. The orange-apricot, which is the next that becomes ripe, the flavour of which is but indifferent. 3. The Algiers apricot ripens next, which is oval-shaped, compressed, and of a straw-colour; this fruit is not much esteemed. 4. The Roman apricot is next in order of ripening, and larger than the Algiers. 5. The Turkey apricot, which is larger than the others, and of a globular form, ripens next, and is much better flavoured than any of those abovementioned. 6. The Breda apricot, supposed to be a native of Africa, is a large roundish fruit, of a deep yellow when ripe, and of an orange-colour; within side the flesh is soft, full of rich juice, and higher flavoured than any of the whole tribe. 7. The Brussels apricot is the last in ripening, it is red on the side next the sun, and of a greenish yellow within side when ripe; the flesh is firm and high-flavoured, but often cracks before it is ripe.—All the sorts of apricots are propagated by inoculation on plum-stocks, and trained in the nurseries either for planting against walls, or for standards; the best soil for these, or any other sort of fruit, is fresh untired earth, from a pasture taken about ten inches deep with the turf, which should be laid to rot and mellow, at least twelve months before it is used. When the former soil of the border is taken away, this fresh earth should supply its place, and if the borders are filled with it two months before the trees are planted, the ground will be better settled, and not so liable to sink after the trees are planted. The ground should be raised four or five inches above the level to allow for settling: the borders being thus prepared, make choice of such trees which are of one year's growth from the budding, and if the soil is dry, the best season to plant them is when the leaves are turned yellow, and ready to fall off in autumn, when they will have time to form fresh roots before winter, and be better enabled to withstand the severity of the weather, as also prepared to shoot more vigorous in the spring; but do not cut off any of the head at that time of planting, unless there be any any strong fore-right shoots which

which will not bend to the wall, and must therefore be cut away. If the soil is very moist, it is better to plant in the spring, just as the sap begins to be in motion: the trees being ready prepared for planting, by cutting the extremities of the roots smooth, and all small decayed fibres off, mark out the distances they are to be planted at, which, in a good strong soil, should not be less than sixteen or eighteen feet; make a hole where each tree is to stand, place the stem about four inches from the wall, inclining the top thereto. After having fixed the tree in the earth, nail the branches to the wall, and pour a pail of water on the root, in order to settle the earth more compactly about it; then cover the surface of the earth round the roots with dung to keep the frost out. In this state they may remain till February, when, if the weather be good, the branches should be unnailed, and with a sharp knife cut down to about four or five eyes above the place of inoculation, sloping the place of incision towards the wall. When the weather becomes hot and dry, it will be necessary to water them, observing to keep some mulch round the roots, which will prevent their drying so soon as if there were none. As new branches are produced, observe to nail them to the wall horizontally, and displace such shoots that grow in a fore-right direction: this must be repeated as often as necessary, but by no means should the branches be topped in summer.— In autumn, when the leaves are dropping off, it will be necessary to shorten the branches in proportion to their strength. A vigorous branch may be left eight or nine inches long, but a weak one not above five or six. By this means, no part of the wall will be left uncovered with bearing-wood, which must be the case if the branches are left at their full length at first, which is practised by some gardeners: but the error must be exposed, when it is seen, that few more buds than two or three shoot from the branches, and these are for the most part produced from the extreme part of the last year's wood, so that all the lower part of the shoots become naked, and this is the reason we see so many trees which have their bearing-wood situated only at the extreme parts of the tree. The second summer observe as in the first, to displace all fore-right shoots as they are produced, nailing in the others close to the wall horizontally, and never shorten any of the shoots in summer, unless to furnish branches to fill vacant places on the wall. At Michaelmas, shorten the shoots as before directed. The following year's management is much the same as the preceding; observing, that apricots produce their fruit not only on free-growing branches, but also on cursons, or spurs, which are produced from two years wood; these spurs, therefore, should not be displaced.

Apricot trees planted against a wall, of a west or east aspect, is best, as the south aspect is rather

too hot for them. The west aspect is preferable, for it generally happens, that, at the time of their being in bloom, the blighting easterly winds prevail, which frequently cut their blossoms off, and greatly damages the tree.

The Brussels and Breda apricots are most commonly planted for standards, and produce fruit of a much richer flavour than those against walls; but the misfortune is, that, by blowing so early, the flowers are very apt to be destroyed by the inclemency of the weather: therefore, instead of training them with stems six or seven feet high, it would be better to have them about half that height; or they may be placed as dwarfs in an espalier, where, if properly managed, they will produce good fruit; and the trees in espalier may be more conveniently covered in the spring when the season proves bad. For a farther account of the management of these trees, see the article PRUNING.

APRIL, in chronology, the fourth month of the year, containing thirty days.

The word is formed from the Latin *Aprilis*, which is derived from *aperis*, to open, because the buds begin to open during this month.

A-PRIORI demonstration. See DEMONSTRATION.

APRON, in the marine, a platform or flooring of plank, raised at the entrance of a dock, a little higher than the bottom, against which the gates are shut. See the article DOCK.

APRON, in naval architecture, a piece of curved timber, fixed behind the lower part of the stem immediately above the fore-end of the keel; it is commonly formed of two pieces, and is used to strengthen the scarf or junction of two parts of the stem. See SHIP-BUILDING, KEEL, STEM.

APRON, in gunnery, a square plate of lead that covers the touch-hole of a cannon, to keep the charge dry. See CANNON.

APSID, in astronomy, is used as well for the highest part of the orbit of any planet, or the point where the planet is at the greatest distance from the sun, as the lowest part of that orbit, when the planet is the nearest to the sun. The line of the apsis, or apides, is a line drawn from the perihelion to the aphelion, as AP, (plate X. fig. 1.)

APSID, among ecclesiastical writers, implies the inner part of the ancient churches, answering to what is at present called the choir.

APSID is also used by some writers for the bishop's seat or throne.

APTHANES. See ABTHANES.

APTOTE, signifies in grammar, a word that is indeclinable, or has no variation of cases.

It is derived from the Greek *a*, without, and *aptosis*, a case.

APUS, in astronomy, a constellation of the southern hemisphere, placed between Triangulum Australe, and the Chamelion near the south pole; by some it is called the bird of Paradise. There are

are four stars of the sixth, three of the fifth, and four of the fourth magnitude in this constellation; but as we have never seen these stars, we shall not give their places.

APYREXY, among physicians, implies the intermission of a fever.

The word is Greek, *απυρεξια*, compounded of *α*, priv. and *πυρ*, fire, or heat.

AQUA, water. See the article WATER.

AQUA-FORTIS, a corrosive liquor distilled from nitre and vitriol, in the following manner.

Put vitriol into an earthen or iron pot; make a fire under it, and the vitriol will begin to melt and smok; increase the fire gradually, and it will thicken and assume an ash-colour. Let it be stirred with a twig before it becomes solid, till it be perfectly dry; but let it be taken as yet boiling out of the pot; for if it grows cold therein, it will stick so fast that you will hardly be able to get it out. Pound to a subtile powder three pounds weight of this calcined vitriol, and mix them well with four pounds of nitre well dried, and pulverized very fine. Put these together in a cucurbit, or retort, or an iron pot, and place the whole in a furnace.

At first, let the fire be made not much greater than is necessary to boil water. When the recipient grows warm, continue the same degree of fire, till all the phlegm is expelled, which you will know from the diminution of the heat of the recipient: increase the fire gradually, till you see a few yellow vapours arise. Keep up the same fire for an hour or two, and make it so strong as to warm the vessels moderately. Continue this for some hours, and letting the vessels cool, pour the liquor, now emitting reddish fumes, out of the recipient into a glass vessel, having a glass stopple: this liquor thus prepared is your aqua-fortis.

You should, for security's sake, leave in the closure of the recipient and vessel that contains the matter to be distilled, a hole, which may be stopped and opened with a wooden peg; for if you happen to exceed the just degree of fire, especially in the beginning of the operation, the first and more subtile spirits, which are very elastic, come forth; the opening therefore of the hole may give them a passage, lest the vessels should burst, which would be very dangerous.

AQUA-MARINA, in natural history, the name of a precious stone of a colour compounded of green and blue, nearly resembling that of sea-water, from whence the name.

It seems very probable that the ancients knew it under the name of the beryl-stone; for Pliny observed that the most beautiful beryls were those that imitated the colour of sea-water; he likewise distinguishes several sorts of beryls, which bear no resemblance with our aqua-marina; as the chrysoberyls, which were of a golden colour. Whatever the ancients called the aqua-marina, we are now to

endeavour to find out a sure means to distinguish this precious stone from all others. The colour being a mixture of green and blue, we cannot find it either with green or blue stones, as the emeralds and the sapphires: for if we suppose the emerald of a pure green, without any tincture of blue, and the sapphire blue as indigo, and free from any tincture of green, we may easily discover that all stones compounded of green and blue can neither be emeralds nor sapphires. This mixture of an emerald-colour with that of a sapphire, that is, of green and blue, describes so well the aqua-marina, that it seems impossible to be mistaken: not but that there are some of these stones, where the green is more predominant than the blue; as well as others, where the blue is more powerful than the green. These stones are very different from each other, with respect to their hardness. The oriental are reckoned the hardest, and bear the finest polish; and consequently are more beautiful, more scarce, and dearer than the occidental.

The most beautiful aqua-marinas come from the East-Indies; and it is said that some of them are found on the borders of the Euphrates, and at the foot of Mount Taurus. The occidental ones come from Bohemia, Germany, Sicily, the Isle of Elba, &c. And it has been affirmed that some of them have been found on the sea-shore.

AQUA-REGIA, a corrosive menstruum that has the power of dissolving gold. It is made in the following manner:

Take one pound of common salt; melt it in a clean crucible or iron ladle; pour it out into an iron mortar, and when cold break it into small pieces. Put these into a retort, and pour upon them twice their weight of good aqua-fortis. Place the retort in a sand furnace: lute on a receiver, and apply a gradual fire, till no more liquor drops from the nose of the retort. An aqua-regia may also be made, by mixing one part of spirit of salt with three of aqua-fortis, or by dissolving the same quantity of sal ammoniac in it: but this should be done slowly, and by degrees, otherwise great quantities of offensive fumes will arise.

This menstruum dissolves iron, copper, tin, gold, mercury, regulus of antimony, bismuth, and zinc; but not silver, unless it be deficient in strength.

AQUÆDUCT, in architecture and hydraulics, is a conduit of water, and signifies an artificial canal, either under ground or raised above it, serving to convey water from one place to another according to their level, notwithstanding the unevenness of the intermediate ground. Thus, the water is carried by conduits, pipes, or aquæducts, from the New River head at Illington to any part of the city of London that has the same height or level with the river's head. The Romans built several very considerable ones in their city; and Julius Frontinus,

nus, who had the direction of them, tells us of nine which discharged themselves through 1314 pipes of an inch diameter : and Blasius upon Livy observes, that these aqueducts brought into Rome above 500,000 hogheads of water in the space of 24 hours.

AQUÆDUCT, in anatomy, a term applied by anatomists to certain canals, on account of their form or use : such are the aquæduct of Fallopius, a canal situated between the apophyses, styloides, and mastoides ; the aquæduct of Nuck, in the sclerotic coat of the eye ; and the aquæduct of Sylvius, in the brain, the posterior surface of which is called its anus.

AQUARIANS, a name given to a sect of Christians, who appeared in the third century : they were so called because they substituted water instead of wine when they administered the sacrament.

In the earliest ages of Christianity, when the people *so furiously raged together* against the proselytes to this religion, its votaries were obliged to assemble by night to celebrate their holy mysteries ; in which case they made use of water instead of wine, that in the morning the smell might not betray them.

Others mixed water with their wine ; because water represents the people, as wine does the blood of Christ : and when both are mixed together, then Christ and his people are united. This practice was confirmed by the council of Carthage : for which two reasons are assigned ; first, because it is according to the example of Christ ; and, secondly, because when our Saviour's side was pierced with the spear, "straightway came there out blood and water." A better reason than either of these might be assigned for the use of water with wine in the eucharist ; and that is, that people might not drink inordinately, so as to abuse themselves, which they were wont to do, even in the apostles times : for St. Paul reproves them for it, and asks them, Whether they have not homes to drink in, that they should so abuse that holy festival ?

AQUARIUS, in astronomy, a constellation, which makes the eleventh sign of the zodiac ; represented by a man (Plate XII.) with a water-pot on his arm inverted, and the water pouring down ; signifying that when the sun enters this sign, which is about the 20th of January, we may expect much rain. Poets tell us this Aquarius, when on earth, was the beautiful youth Ganymede, son of Tros and Callirhoe, whom an eagle sent by Jupiter snatched off mount Ida as he was hunting, and carried him into heaven, where Jupiter made him his cup-bearer, and on whom he attends at all banquets with flowing cups of nectar. Others notwithstanding think it to be Deucalion, the son of Prometheus, whom the gods translated to heaven, in remembrance of that mighty deluge which happened in his time, whereby mankind was almost entirely swept from the earth. The following is a catalogue of stars in this constellation, settled to 1770.

Order.	Magni.	Name.	Right Ascension.	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination.
1	6		306.46.45	90.20.47	46.10	12.50
2	4	e	308.48.11	100.19.23	49.5	12.53
3	5		308.45.54	95.53.42	48.15	12.54
4	6		309.40.20	96.34.52	48.15	12.61
5	6		309.50.48	96.23.54	48.15	12.72
6	5	μ	310.3.28	99.49.54	48.52	12.87
7	6		310.58.13	100.36.12	48.52	12.99
8	7		311.40.48	103.58.29	44.40	13.20
9	6		311.58.10	104.27.16	50.10	13.42
10	6		311.57.1	96.24.14	48.15	13.51
11	6		311.56.5	95.38.8	48.10	13.63
12	6		312.50.29	96.45.25	48.15	13.75
13	5	ν	314.15.41	102.17.49	49.18	13.94
14	6		315.51.6	100.12.1	48.30	14.20
15	6		316.23.29	95.34.39	47.40	14.31
16	6		317.7.17	95.34.28	47.40	14.45
17	6		317.30.19	100.19.30	48.40	14.57
18	6		317.45.50	103.53.37	49.33	14.69
19	6		318.4.19	101.45.16	48.35	14.80
20	6		318.4.50	94.24.56	46.58	14.95
21	6		317.10.52	94.34.34	46.58	15.11
22	3	β	319.51.30	96.34.18	47.42	15.31
23	6	ε	321.22.25	98.51.7	48.15	15.41
24	6		321.49.8	91.7.11	47.42	15.53

AQUATIC, in natural history, is an appellation given to such things as live or grow in the water.

AQUEDUCT, the same with aquæduct. See **AQUÆDUCT**.

AQUEOUS, something abounding with water, or that partakes of its nature.

The word is formed from the Latin, *aquosus*, which is derived from *aqua*, water.

AQUEOUS Humour, in anatomy, called also the albugineous humour, is the utmost of the three humours of the eye, and fills up both its camera. In this the uvea fluctuates as it were, and moves at liberty: this humour also, when lost, will be repaired by nature.

AQUIFOLIUM, or **AGRIFOLIUM**. See **ILEX**.

AQUILA, the eagle, in natural history. See the article **EAGLE**.

AQUILA, in astronomy, a constellation of the northern hemisphere, represented by an eagle. The poetical reason of the eagle having a place in the heavens is this; Jupiter transforming himself into the form of an eagle, took Ganymede (whom he greatly loved) into heaven; and therefore, because by means of the eagle he executed his purpose, placed the figure among the constellations in remembrance of the action. Others say, that Jupiter was brought up in a cave in Crete by doves, who fed him with ambrosia; and an eagle with nectar, which he drew from a rock, and carried in his bill: for this he was honoured with celestial dignity. Others say, that in the wars of the giants the eagle brought thunder to Jupiter, with which he quelled them, and is therefore called Jove's armour-bearer. The following are the stars in this constellation, together with Antinous, according to the order of the British Catalogue, settled to the year 1770.

AQUILA Marina, the sea-eagle, the name of a fish of the pastinacha kind, with a head resembling in some measure that of a toad.

AQUILEGIA, *Columbine*, in botany, a genus of polyandrious plants, the flowers of which are pendulous and destitute of an empalement, but consist of five plain lanceolated petals expanded. Within the flower are five nectariums ranged alternately with the petals, each of the horns widening upward, the opening being oblique to the side as it ascends, and is annexed to the receptacle, with the lower part lengthening gradually into a long tube hanging by an obtuse apex: the filaments are numerous, topped with oblong erect antheræ. It hath five oval germens, supporting five awl-shaped styles, which are longer than the stamina, and crowned with single upright stigma: each germen afterwards becomes a membranous capsule, which is upright and cylindrical, containing many oval shining seeds. The columbine makes an agreeable appearance in gardens, producing flowers of various colours, which blow in May or June: they are propagated either by sowing the seeds or parting the roots, the proper season for which is in autumn. The official sort is the simple or wild columbine: the leaves, flowers, or seeds may be used. It moderately warms, dries, and opens; whence it obtains a place in prescriptions against the jaundice, and such-like ill habits, arising from obstructions. It was formerly much esteemed for throwing out the small-pox and measles: a water was distilled from it, and a conserve made of its flowers; but in the present medical practice it is much disused.

AQUILICIA, or **AQUILICIANA**, in antiquity, sacrifices performed by the ancient Romans, in times of excessive drought, to obtain rain from the gods.

AQUOSE, the same with aqueous. See **AQUEOUS**.

ARA, or **ALTAR**, in astronomy, a constellation of the southern hemisphere, containing eight stars. The poets gave the following account of the altar's being placed in heaven as a constellation. When the giants, called the Titans, were at war with Jupiter, and used their utmost efforts to pull him out of heaven, the gods thought it necessary to meet together, to consult what was best to be done to keep those Titans out of heaven. Their conclusion was, that they should all join together to fight their enemies; and to ratify this their league, they caused the Cyclops to make them an altar. About this altar all the gods assembled, and swore, that with one consent they would withstand their enemies. Afterwards having got the victory, it pleased them to place the altar in heaven, as a memorial of their league, and a token of the great benefits that arise from unanimity and concord. The stars in this constellation

not

not being visible to us, we shall omit giving their places.

ARABESQUE, or ARABESK, something done after the manner of the Arabians.

ARABIAN, something that relates to Arabia, or the Arabs.

ARABIAN, or ARABIC *Tongue*, is a branch or dialect of the Hebrew.

Father Angelo de St. Joseph speaks much of the beauty and copiousness of the Arabic: he assures us it has no less than a thousand names for a sword, five hundred for a lion, two hundred for a serpent, and eighty for honey.

ARABIAN *Figures* or *Characters*, the numeral figures commonly used in arithmetical computations.

The origin of these characters has been a subject of dispute in the republic of letters. The learned are generally of opinion that the Arabic figures were first taught us by the Saracens, who borrowed them from the Indians. Scaliger was so satisfied of their novelty, that he immediately pronounced a silver medalion he was consulted about modern, upon his seeing of the numeral figures 234, 235, on it. The common opinion is, that Planudes, who lived towards the close of the thirteenth century, was the first Christian who made use of them. Father Mabillon even assures us, in his work *de Re Diplomatica*, that he has not found them any where earlier than the fourteenth.

Yet Dr. Wallis insists on their being of a much older standing; and concludes they must have been used in England at least as long ago as the time of Hermannus Contractus, who lived about the year 1050; if not in ordinary affairs, yet at least in mathematical ones, and particularly astronomical tables. *Vid Wall. Algeb.*

The same author gives us an instance of their antiquity in England, from a mantle-tree of a chimney in the parsonage-house of Helendon in Northamptonshire, wherein is the following inscription in basso relievo, M^o. 133, being the date of the year 1133. *Philos. Transact.* N^o. 255.

Mr. Luffkin furnishes a yet earlier instance of their use, in the window of a house, part of which is a Roman wall, near the market-place in Colchester; where between two carved lions stands an escutcheon containing the figures 1090. *Philos. Transact.* N^o. 255.

Mr. Huet is even of opinion, that these characters were not borrowed from the Arabs, but from the Greeks; and that they were originally no other than the Greek letters, which we all know that people made use of to express their numbers by.

ARABIAN *Philosophy*, the state of philosophy among the ancient Arabians.

Authors of great antiquity inform us, that the ancient Arabians applied themselves very much to

philosophy, and distinguished themselves by a peculiar and superior sagacity; but all they say on this head seems very uncertain. Indeed, after Islamism, learning and the study of philosophy were greatly esteemed among this people; but this has no place in history till we come to the philosophy of the middle age; and consequently proves nothing with regard to the philosophy of the ancient inhabitants of Arabia Felix.

Some men of letters have asserted, that the ancient Arabs applied themselves to philosophical speculations; and to maintain their opinion, raise imaginary systems, which they attribute to them, and draw in the religion of the Sabæans to their aid, which they pretend to have been the offspring of philosophy. But all they advance in favour of this opinion is founded on assertions and conjectures: and what are those where proof and testimony are wanting? They are even forced to acknowledge that the Greeks were of another opinion, looking on them as a most barbarous and ignorant people, without the least tincture of learning. If credit may be given to Abulfaragius, the Arabian writers themselves confess, that before Islamism they were sunk in the deepest ignorance.

These reasons, however, do not seem strong enough to those on the other side of the question to induce them to retract their opinion of the philosophy they attribute to the ancient Arabs. The contempt the Greeks express for this nation, say they, proves only the pride of the Greeks, not the barbarism of the Arabians. But what authority can they produce, or what writers can they quote, in favour of their opinion concerning the philosophy of the ancient Arabians? They agree with Abulfaragius that there are none: this opinion, therefore, stands on a very weak foundation.

Joseph Peter Ludewig has signalized himself most in this dispute, and seems to have had the honour of the ancient Arabians very much at heart. He sets out in this manner: "Pythagoras (says he) as Porphyry relates, in his travels to improve his learning, did the Arabians the honour of a visit; staid some time among them, and learned of their philosophers divination by the chirping and flight of birds; an art in which they excelled. Moses himself, instructed in all the learning of the Egyptians, chose Arabia for a retreat in his exile, preferable to other countries. Can one imagine the great legislator of the Hebrews would have chose this retreat if the people had been barbarous, stupid, and ignorant? Besides, their origin leaves no room to doubt of the improvement of their mind: they boast of their lineage from Abraham, whom no one can deny to have been a great philosopher. By what strange accident is that spark of philosophic spirit extinguished, which they inherited from their common father Abraham? But what yet appears a stronger

“ stronger argument is this, that the sacred writings, to give a more exalted idea of Solomon’s wisdom, place it in opposition to the wisdom of the wise men of the East, which is certainly Arabia. From Arabia also came the queen of Sheba to admire the wisdom of the philosopher invested with a diadem; this has been the constant opinion of all men of erudition. It is easy to prove that the Magi, who came out of the East to worship our Saviour, were Arabians. In short, Abulfaragius is obliged to agree, that before the time of Islamism, to whom the revival of learning in that country is owing, they were perfect masters of their own language, good poets, excellent orators, and able astronomers. Is not this enough to give them a right to the title of philosophers?”

No, it may be replied, the Arabians might have polished their language, have succeeded in composition, have been skilful in the solution of riddles, and interpretation of dreams; nay, though it be admitted they had some knowledge of the courses of the stars, it will not follow they were philosophers; for all those arts, if they merit the name, tend more to increase and encourage superstition, than to discover truth, or disvest the soul of the passions which enslave it. As to what concerns Pythagoras, nothing is more uncertain than whether he travelled into the East or no: but admitting he did, what are we to conclude, but that he learned from the Arabians all those superstitious and extravagant notions he was so extremely fond of? It is needless to quote Moses here; if this great man went into that country, and settled there, by marrying one of Jethro’s daughters, it certainly was not with a design of studying and encouraging them in their foolish curiosity in philosophical systems. Providence permitted this retreat of Moses among the Arabians, to carry among them the knowledge of the true God, and his religion. The philosophy of Abraham, from whom they boast their descent, by no means proves their having cultivated this science. Abraham might have been their progenitor, and a great philosopher; but their philosophy is no necessary consequence of this. If they lost the thread of those most valuable truths they had learned from Abraham; if their religion degenerated into gross idolatry; why might not their philosophy, admitting Abraham to have taught it them, have been lost also in course of time? Besides, it is not certain that these people descended from Abraham. This is a traditionary tale, that seems to have taken birth with Mahometanism. The Arabians, like the Mahometans, to give the sanction of authority to their errors, have pretended to deduce their origin from the father of the faithful. Another thing that overturns Ludewig’s hypothesis is, that Abraham’s philosophy is a mere device of the Jews, who would fain persuade us

that the origin of all arts and sciences is to be found among them. What they say in support of the queen of Sheba’s coming to visit Solomon on the fame of his wisdom, or of the wise men who came out of the East to Jerusalem, will prove nothing more than has been advanced before. Let it be granted that this queen was born in Arabia, is it proved she was of the sect of the Sabians? No one will pretend to deny her to have been the most expert and sagacious woman of her time, and that she frequently puzzled all the kings of the East with her wise questions; because the sacred writings have given this account of her. But what has this to do with the philosophy of the Arabians? We acknowledge very freely that the Magi who came out of the East were Arabians; that they were not without some knowledge of the courses of the stars: we do not absolutely exclude the Arabians from this science, and admit they spoke their native language well; succeeded in some works of invention, as oratory, poetry, &c. but we are not to infer from hence that they were philosophers, and had applied themselves industriously to the cultivation of this part of literature.

A second argument in favour of the philosophy of the ancient Arabians, and which is urged as a very forcible argument too, is the history of Sabianism, which necessarily implies philosophical knowledge, supposing all to be true which is said about it. We cannot conclude any thing from thence in favour of this opinion: for Sabianism is in itself a mixture of shameful idolatry and ridiculous superstition; much more likely to subvert and extinguish reason, than propagate true philosophy; besides, it is not agreed in what age this sect first appeared. Men of the greatest eminence for learning, who have laboured to give light to this passage in history, as Hottinger, Hyde, Pocock, and especially the learned Spencer, confess that there is no mention made of this sect, either by the Greeks or Romans.

We must take care not to confound these Sabians of Arabia with those mentioned in the annals of the ancient eastern church, which were half Jews half Christians; and boasted of being the disciples of St. John the Baptist; great numbers of whom, even to this day, inhabit the city of Bassora, near the banks of the Tigris, and the neighbourhood of the Persian sea. The famous Moses Maimonides has extracted a large account of this sect from the Arabic writers, and by examining their extravagant and superstitious ceremonies with attention, has very ingeniously justified the laws of Moses in general; which, at first might give offence to delicacy, if the wisdom of these laws was not shewn by their opposition to the laws of the Sabians. A stronger barrier could not be put between the Jews and Arabians, who were their neighbours.

The Arabian philosophy was entirely Sabian, and included the system and ceremonies of that sect of idolators. This was what Mahomet laboured so strenuously to abolish; and he is even said by some to have carried his opposition so far as to prohibit the very study of philosophy. But his followers by degrees got over that restraint; the love of learning increased, and the philosophy of Aristotle was established among them, during the memorable caliphate of Al-Mamon. Avicenna flourished in the eleventh century, and Averrhoes an hundred years after him; so that the honour of translating the Greek philosophy into Arabic, cannot belong to them, notwithstanding what has been said on that subject; though they were doubtless the chief propagators of it through the countries of Europe.

Their method of philosophizing was faulty; they followed Aristotle implicitly, and run into all the strange superstitions of astrology. They founded schools and academies, became fond of subtilties and disputation, and soon divided into different sects.

As they chose Aristotle for their master, so they chiefly applied themselves to that part of philosophy called logic; and thus became proficient in the knowledge of words, rather than of things: whence they have been called the talking philosophers, and masters of the wisdom of words. Their philosophy was obscured by quaint arbitrary terms and notions, and on these, instead of evident principles, their demonstrations were founded.

ARABIAN *Poetry*, in the most ancient times, was no other than rhiming; for it was destitute both of measure and cadence. But about the close of the eighth century, and during the caliphate of Al-Rachid, it became an art, and was regulated by laws of prosody. It however still makes no distinction between long and short syllables, the whole depending on rhyme, a certain number of letters, and the observation of certain censure, formed by carefully distinguishing the moveable from the quiescent consonants. A syllable to which a quiescent letter is added at the end, becomes long by position; and, on the contrary, that syllable short where it is wanting.

Renaudot tells us, that the Arabian compositions in verse are still wild and irregular, being neither epic, dramatic, nor lyric; in short, not reducible to any particular kind. Their hymns to the deity, and their tales, are in the same style. Their comparisons, in which they abound, are taken, with very little choice, from tents, camels, hunting, and the ancient manners of the Arabs.

ARABIAN *Physic*, and *Physicians*, succeeded the Grecian, and handed down the art to us, with considerable improvements, chiefly in the pharmaceutical and chemical parts.

ARABICI, in ecclesiastical history, the name of

a sect of heretics that appeared in Arabia during the reign of the emperor Severus, about the year 207. Their hereby consisted in holding that the soul both dies and rises again with the body. Origen confuted them so fully, that they ingenuously acknowledged their error.

GUM ARABIC. See GUM *Arabic*.

ARABISM, an idiom or manner of speaking peculiar to the Arabs, or Arabic language.

ARABLE *Land*, in husbandry, that which is fit for tillage, or has actually been plowed.

The word is derived from the Latin, *aratrum*, a plow.

ARAC, or ARRAC, a spirituous liquor imported from the East-Indies.

It is extracted from a vegetable juice called toddy, which flows by incision from the cocoa-nut tree. This juice, after being fermented, is distilled in the common manner, and the produce is the arac.

ARACHNOIDES, in anatomy, is an appellation given to several different membranes, as the tunic of the crystalline humour of the eye, the external lamina of the pia mater, and one of the membranes of the spinal marrow.

The word is Greek, and compounded of *αράχνη*, a spider, or spider's-web, and *ειδος*, resemblance; the fineness of these membranes being supposed to resemble that of the spider's web.

ARÆOMETER, or WATERPOISE, an instrument for measuring the weight of liquors; which is usually made of a thin glass ball, with a long tapering neck, hermetically sealed at the end, after as much mercury has been put in as will keep it swimming in an upright posture. The neck is divided into several parts to shew the different densities of the different liquors into which it is put to swim; for the lighter the fluid the deeper the glass ball will sink; and vice versa. See HYDROMETER.

ARÆOPAGUS. See AREOPAGUS.

ARÆOSTYLE, in architecture, a term used by some architects to signify the greatest interval that can be made between two columns, which consists of eight modules or four diameters. See MODULE.

ARÆOTICS, in medicine, remedies which rarify the humours, and render them proper for being carried off by perspiration through the pores of the skin.

The word is formed from the Greek, *αραίωτις*, which is derived from *αραιω*, to rarify.

ARAIGNEE, in the military art, signifies the branch, return, or gallery of a mine. See the article MINE.

ARANEA TUNICA, or ARANEOSA, in anatomy; see the article ARACHNOIDES.

ARANEA CONCHA, the spider-shell, in natural history, a name given to several species of the murex. See MUREX.

ARBALET, in antiquity, a kind of weapon, generally called at present a cross-bow. See the article **Cross-bow**.

The antients had also large machines of the same kind for throwing several arrows at a time. These were generally called *ballistæ*. See **BALLISTA**.

ARBITER, in the civil law, implies a judge nominated by the magistrate, or chosen voluntarily by the two contending parties, in order to decide their differences according to law.

The civilians make a difference between arbiter and arbitrator, though both found their power on the compromise of the parties; the former being obliged to judge according to the customs of the law, whereas the latter is at liberty to use his own discretion, and accommodate the difference in the manner that appears to him most just and equitable.

ARBITRARY, whatever is left to the choice or determination of men, or not fixed by any positive law or injunction. Thus arbitrary fines are mulcts imposed at the pleasure of the court or judge.

ARBITRARY Power. See **DESPOTISM**.

ARBITRATION, **ARBITRAGE**, or **ARBITRAMENT**, a power given by two or more contending parties to some person or persons to determine the dispute between them.

ARBITRATOR, a private extraordinary judge, chosen by the mutual consent of both parties, to determine controversies between them.

ARBOR, the Latin appellation for any tree in general.

ARBOR Dianaæ. See **DIANE Arbor**.

ARBOR Vitaæ. See **THUYA**.

ARBOR, in mechanics, the chief or principal part of a machine, or that part which sustains the rest; thus the axis, or spindle, on which the machine turns is called the arbor, as the arbor of a wind-mill, the arbor of a water-wheel, of a gin, &c.

ARBORESCENT, a term applied to all such things as resemble trees; thus we read of arborescent shrubs, arborescent animals, &c. of which last kind is that great natural curiosity the star-fish.

ARBORIST, a person skilled in the nature and management of trees.

ARBOUR, in gardening, a shady place to sit in, formed of lattice-work, and entirely covered, except the entrance, with clipped trees, as elms, limes, hornbeam, &c. or with twining plants, as jessamines, honeysuckles, &c. Arbours now are not so much in esteem as formerly, they being unhealthful to sit in, except in very hot and dry weather, and likewise expensive to keep in repair, the wood-work soon rotting by being continually in the shade, and excluded from the free air. Those that delight in arbours may make them without lat-

tice-work, by planting elms, &c. of about nine or ten feet high, at the distance of three feet in the line on each side, and fastening their tops together so as to form an arch, but as they are apt to get bare at their bottoms, it may be necessary to plant between each a shorter tree, filling the interstices with honeysuckles, jessamines, &c. which will make the whole quite full, and by being properly kept clipped, it will appear very handsome.

ARBUTUS, the strawberry-tree, in botany, a genus of ever-green trees, producing oblong leaves sawed at the edges, the flower is monopetalous and ovated, divided into five segments at the brim, which are reflexed; it hath ten short filaments joined to the bottom to the corolla, topped with bifid anthers. At the bottom of the flower is placed a globular germen supporting a cylindrical style, crowned with a thick blunt stigma: the germen afterwards turns to a roundish berry very like a strawberry, from whence the English name is taken, but divided into five cells, in which are contained many small seeds.

There are five species in this genus: 1. The common *arbutus*. 2. *Arbutus* with plain leaves, called by some *adrachne*. 3. *Arbutus*, called the bilberry of Arcadia, with alaternus leaves. 4. *Arbutus*, called the bilberry, with oblong whitish leaves. 5. *Arbutus*, called *uva ursi*, or bear-berries. With two or three varieties of the first sort.

The fruit of the common *arbutus* being ripe at the latter part of the year, the seeds should be washed from the pulp, and preserved in dry sand till the month of March, when they should be sown in pots, and plunged in old tan, on a moderate hot-bed, which will be serviceable to promote vegetation. The seeds will soon come up, when they must be kept frequently watered during the summer: in autumn, the young plants may be placed singly in small pots, and plunged in old tanners bark, under glasses during the winter, and should be protected from the frosts by proper covering. The succeeding winter they should be hardened to the weather, more than in the preceding, by covering them only with mats in severe weather, so that they may the following winter be so much inured to the climate, as to bear planting in the shrubbery, where they are designed to remain, which should be in the spring following. These plants may be also propagated by cuttings, or layers; but the best are those raised from seeds.

ARC, or **ARCH**. See the article **ARCH**.

The word is formed from the Latin, *arcus*, bow.

ARCANUM, a secret, generally used to imply a remedy, whose composition is concealed, in order to increase its value.

ARCA CORDIS, in anatomy, the same with pericardium. See **PERICARDIUM**.

ARCA-

ARCADIANS, the name of a society of men of letters, who formed themselves into a body at Rome, in the year 1690, with a design to preserve learning, and carry Italian poetry to perfection.

They took the name of Arcadians, partly from the rules of their society, and partly from every new member's assuming, on his admission, the name of some shepherd of ancient Arcadia. Once in four years they elect a president, under the title of guardian, appointing him twelve fellows, who decide all affairs of the society. The famous Christina, queen of Sweden, was their first patroness. They reckon by Olympiads, and celebrate their festivals of wit every fourth year.

ARCBOUTANT, in building, an arched buttress. See **BUTTRESS**.

ARCH, in geometry, any part of a curved line intercepted between two points.

ARCH of a Circle is any part of its circumference.

Circular ARCHES are of three kinds, viz. semicircular arches, skene arches, and arches of the third and fourth point.

Semicircular ARCHES are such as have their centers in the middle of a line, joining the two feet together.

Skene ARCHES are segments of circles, containing sometimes more than 90°. and sometimes less.

ARCHES of the third and fourth point, or *Gothic ARCHES*, are such as consist of two arches of a circle, meeting in an angle at the vertex of the arch, being drawn from the division of a chord into three or four parts at pleasure.

Catenarian ARCH. See **CATENARIAN**.

Diurnal ARCH, in astronomy, is that curve or part of a circle described by a star, planet, &c. from its rising and setting.

Elliptical ARCHES are semi-ellipses, usually described by workmen on three centers.

Equal ARCHES are such as contain the same number of degrees of a circle, swept with the same radius.

Mural ARCH. See **MURAL Arch**.

Nocturnal ARCH is that part of a circle described by a star or planet from its setting to rising.

ARCH of Direction, or *Progression*, is the arch of the zodiac which a planet appears to move over when in sequentia, or according to the order of the signs.

ARCH of retrogradation, is an arch of the zodiac described by a planet when in its retrograde motion, or its motion contrary to the signs.

ARCH, in architecture, a concave building with a mould bent in form of a curve, erected to support some structure.

Triumphal ARCH, a stately gate of a semicircular form, adorned with sculpture, inscriptions, &c. erected in honour of those who had deserved a triumph.

ARCH of Vision, is an arch of a vertical circle, intercepted between the center of the sun, after its setting, and the horizon, when a star before was hid in its rays, and again begins to appear.

Strait ARCHES are those used over doors and windows, having plain strait edges both above and below, parallel to each other, but both the ends and joints pointing to a center.

THEORY of arches. See the article **BRIDGE**.

ARCHÆUS. See **ARCHEUS**.

ARCHANGEL, in scripture, signifies a divine and spiritual being, who is sent by the Almighty on extraordinary occasions to declare his will, or execute his commands. He is the second in the third hierarchy. See **ANGELS**, **HIERARCHY**.

The word is compounded of the Greek *αγγελος*, a messenger, and *αρχος*, chief.

ARCHBISHOP, a prelate who has several suffragan bishops under him. The name was not known in the first ages of the church, but was invented by the Greeks, from whom it passed into the western churches. In the infancy of Christianity, they made use only of the word bishop, and when they would distinguish one who had other bishops under him, they called him the first bishop. Some are of opinion, that the patriarchs of Alexandria gave themselves first of all the name of archbishop, when other bishops were created in Egypt, where there had formerly been no more than the patriarch, the only bishop.

The jurisdiction of an archbishop consisted originally in ordaining, or ratifying the ordinations of all other bishops; and once a year he was to summon them all to a synod, in which he presided, to enquire into their conduct, and censure them with suspension, or deprivation; as also to hear and determine causes between contending bishops.

The first establishment of archbishops in England, if we may credit Bede, one of the most ancient writers of the English nation, was, in the time of Lucius, said to be the first Christian king in England, who, after the conversion of the people, erected three archbishopsricks, in London, York, and Landaff. The dignity of archbishop continued in the see of London 180 years; when it was translated to Canterbury, where it has remained ever since. York is a metropolitan see to this day. The archbishop of Canterbury is styled, "Primate and Metropolitan of ALL England;" and the archbishop of York, "Primate and Metropolitan of England."

ARCHBUTLER, one of the great officers of the German empire, who presents the cup to the emperor on solemn occasions. This office belongs to the king of Bohemia.

ARCHCHAMBERLAIN, an officer of the empire, nearly the same with the great chamberlain of England. The elector of Brandenburg was appointed archchamberlain, by the golden bull.

ARCHCHANTOR, the president of the chantors of a cathedral or collegiate church.

ARCHDEACON, the name of an ecclesiastical dignitary, whose business it is in the parishes subject to his jurisdiction, to enquire into the repairs of churches, reform abuses, suspend, excommunicate, &c.

In England there are sixty archdeacons.

ARCH-DUKE, a title given to dukes of greater authority and power than other dukes.

ARCHE, among physicians, implies the beginning or first period of a disease.

The word is Greek, ἀρχη, and signifies beginning.

ARCHED Legs, in horsemanship, when the knees of a horse are bended in the form of an arch. This is reckoned a very great fault, and is often occasioned by hard travelling.

ARCHER, in the ancient military art, implied a person who fought with a bow and arrows.

ARCHES, or *Court of ARCHES*, the supreme court belonging to the archbishop of Canterbury, to which appeals lie from all the inferior courts within his province.

ARCHETYPE, the first or original model of a work, which is copied after to make another like it.

The word is compounded of the Greek, ἀρχη, beginning, and τυπος, a type.

This term is used by minters, to signify the standard weight by which the others are adjusted.

ARCHEUS, among chemists, implies the predominating principle of things, whereby their peculiar qualities are fixed and determined. Others, however, mean by this term a certain universal spirit diffused through the whole creation, and which is the active cause of all the phenomena in nature. They even attribute ideas to the archeus, and thence call them archeal ideas.

ARCHIATOR, the chief or principal physician of a prince, who retains several of the faculty.

The word is Greek, ἀρχιατρος, and compounded of ἀρχη, chief, and ιατρος, a physician.

ARCHIL, *Archilla*, in botany, a whitish moss growing upon rocks in the Canary and Cape Verd Islands, and which yields a rich purple tincture, fugitive indeed, but extremely beautiful.

This weed is imported to us as it is gathered: those who prepare it for the use of the dyer, grind it betwixt stones, so as to thoroughly bruise, but not reduce it into powder, and then moisten it occasionally with a strong spirit of urine, or urine itself mixed with quick-lime: in a few days it acquires a purplish red, and at length a blue colour: in the first state it is called archil, in the latter lacmus, or litmose.

The dyers rarely employ this drug by itself, on

account of its dearth and the perishableness of its beauty. The chief use they make of it is, for giving a bloom to other colours, as pinks, &c. This is effected by passing the dyed cloth or silk through hot water lightly impregnated with the archil. The bloom thus communicated, soon decays upon exposure to the air. Mr. Hellot informs us, that by the addition of a little solution of tin this drug gives a durable dye: that its colour is at the same time changed towards a scarlet; and that it is the more permanent, in proportion as it recedes the more from its natural colour.

Prepared archil very readily gives out its colour to water, to volatile spirits, and to spirit of wine: it is the substance principally made use of for colouring the spirits of thermometers. As exposure to the air destroys its colour upon cloth, the exclusion of the air produces a like effect in these hermetically sealed tubes; the spirits of large thermometers becoming, in the compass of a few years, colourless. M. l'Abbé Nollet observes (in the French Memoirs for the year 1742) that the colourless spirit, upon breaking the tube, soon resumes its colour, and this for a number of times successively; that a watery tincture of archil, included in the tubes of thermometers, lost its colour in three days; and that in an open deep vessel it became colourless at the bottom, whilst the upper part retained its colour.

A solution of archil in water, applied on cold marble, stains it of a beautiful violet or purplish-blue colour, far more durable than the colour which it communicates to other bodies.

Mr. du Foy says he has seen pieces of marble stained with it, which in two years had suffered insensible change. It sinks deep into the marble, sometimes above an inch; and at the same time spreads upon the surface, unless the edges be bounded by wax, or other like substances. It seems to make the marble somewhat more brittle.

Linnaeus informs us, in the Swedish Transactions for the year 1742, that the true archil moss is to be found on the western coasts of England; and suspects that there are several other more common mosses from which valuable colours might be extracted. A quantity of sea-moss having rotted in heaps upon the shore, he observed the liquor in the heaps to look like blood; the sea-water, the sun, and the putrefaction, having brought out the colour. Mr. Kalm, in an appendix to Linnaeus's paper in the year 1745, mentions two sorts of mosses actually employed in some parts of Sweden for dying woollen red: one is the *Lichenoides coralliforme apicibus coccineis* of Ray's Synopsis; the other the *Lichenoides tartareum farinaceum, sustentiarum umbone fusce*, of Dillenius. This last is a white substance, like meal clotted together, found on the sides and tops of hills. It is shaved off from the rocks after rain, purified from the stony matters intermixed among it

by washing with water, then dried in the sun, ground in mills, and again washed and dried: it is then put into a vessel with urine, and set by for a month. A little of this tincture, added to boiling water, makes the dying liquor. In the same Transactions for the year 1754, there is an account of another moss, which, prepared with urine, gives a beautiful and durable red or violet dye to wool and silk. This is the *Lichen foliaceus, umbilicatus, subtus la-cunosus*, Linn. flor. Succ. It grows upon rocks, and is readily distinguished from others of that class, by its looking as if burnt or parched; consisting of leaves as thin as paper, convex all over on the upper side, with corresponding cavities underneath, adhering firmly to the stones by a little root under the leaves, and coming asunder, when dry, as soon as touched. It is gathered after rain, as it then holds best together, and parts easiest from the stone.

In France, a crustaceous moss, growing upon rocks in Auvergne, is prepared with lime and urine, and employed by the dyers as a succedaneum to the Canary archil, to which it is said to be very little inferior: it is called oreille d'Auvergne, or perelle. Mr. Hellot relates, that he has met with several other mosses, which, on being prepared in the same manner, acquire the same colour. The most expeditious way, he says, of trying whether any moss will yield an archil or not, is, to moisten a little of it with a mixture of equal parts of spirit of sal ammoniac and strong lime-water, and add a small portion of crude sal ammoniac; the glass is then to be tied over with a piece of bladder, and set by for three or four days. If the moss is of the proper kind, the little liquor which runs from it upon inclining the vessel, will appear of a deep crimson colour; and this afterwards evaporating, the plant itself acquires the same colour. *Lewis's Notes on Neumann's Chemistry*.

ARCHILOCHIAN, a name given to a species of verse invented by Archilochus, a poet of Paros, one of the isles of Cyclades. This poet was promised by Lycambus that he should have his daughter in marriage, but was deceived by him; which so irritated the bard, that he wrote some severe iambics against him, which touched him so sensibly, as to make him hang himself. Horace alludes to this, when he says,

Archilochum proprio rabies armavit Iambo.

Iambics, according to Quintilian, were invented by him, *Archilochus primus inter eos, qui Iambo scripsere; summa in eo vis, elegantes sane, vibrantesque sententiae; plurimum sanguinis et nervorum.* "Archilochus was one of the first who wrote Iambics; he has amazing power; his thoughts are elegant and striking; and he is possessed of the greatest strength and vigour." There is another species of verse called after him, which consists of seven feet, whereof the four first are generally dactyls, though

sometimes spondees, and the three last trochees: such is this of Horace,

Jam Cytherea choros ducit Venus, imminente luna.

ARCHIMANDRITE, was anciently the name given to a superior of a convent, and answers to what is now called a regular abbot. The word *mandrite* is Syriac, and signifies a recluse or monk.

ARCHIPELAGO, in geography, a part of the sea, containing, or interrupted by, many little islands; but is most commonly applied to that part between Greece and Asia.

ARCHISYNAGOGUS, the chief of the synagogue; the title of an officer among the Jews, who presided in their synagogues and assemblies.

The number of these officers was not fixed, nor the same in all places; there being seventy in some, and in others only one. They are sometimes called princes of the synagogue, and had a power of excommunicating such as deserved that punishment.

ARCHITECT, a person well skilled in architecture, who delineates, or draws plans of edifices, conducts the work, and directs the artificers employed therein.

ARCHITECTONIC, something endowed with the power and skill of building, or calculated to assist the architect.

ARCHITECTURE, the art of erecting edifices or buildings, whether for habitation or defence.

Mankind has varied their abodes from time to time, according to local conveniences, and according to the different genius and character of every people and nation. The first method of building houses that we have any idea of since the deluge, is that of the children of Noah in Gorduena, or Kurdistan, where the ark rested. The appendices of rocks, caves, and hollow places dug under the ground, were the first retreats of their families, as soon as they increased in number in that mountainous land; these were the places they sheltered themselves in from rains and sharp winds, but not from damps and obscurity. The barrenness of those regions soon drove them over the river Tigris, into the plains of Mesopotamia. Here the want of stone, or any other hard matter fit for making them shelters, taught them the art of brick-making, and hence the art of masonry. For mortar they made use of viscous bitumen, which they mixed or thickened with reeds, or straw cut small. The woods which were easily found almost in every place, they soon learned was the most pliant, as well as durable matter, for making roofs and linings, as well as pieces for support. Strangers to skill and experience, they at first contented themselves with huts, or green arbours, void of symmetry or proportion; but as wood took whatever form they pleased to give it, the tools,

tools, which they gradually invented, taught them by degrees to turn it into hurdles, poles, beams, joists, boards, laths, and pieces of all shapes and magnitudes: therefore, we may reckon the plainness of the wood, and the skill of the hurdlor and carpenter, to be the first causes to which we are indebted for this manner of building, which was most universal in the beginning, and which has rendered the earth truly habitable.

The Egyptians, after having minutely examined the two sides of the Nile, fixed their abodes in the plains which it most fertilized, and brought thither by help of navigation, stone, marble, and other matter for building, which they found in great plenty at the farther end of Africa. Hence those magnificent buildings in form of terrasses; and those lofty monuments, which are found superior to inundations, and not to be destroyed by all the efforts of water.

The elegance that shines throughout the writings of the Greeks is likewise found in their architecture, and in all their inventions. We had from them the first operations of geometry, the correctness of drawing the several orders of architecture, the beautiful proportions in every thing, and the principles of all the liberal arts.

The Romans, less civilized, at first built their houses with wood, earth, and stubble: nevertheless, a spirit of nobleness appears in their primitive simplicity; for they never spared any thing to perfect the edifices for common utility.

The inconveniencies and decay of wooden buildings brought masonry more and more into request, both for public and private use; society was a double gainer by it; the structures becoming at once more elegant and more commodious; at the same time timber, so necessary in navigation, and in so many other purposes, was considerably spared. It has, however, still a principal share in the construction of most buildings; it sometimes supplies the whole carcass, or what is commonly called the frame, which is afterwards filled up with slight masonry; it likewise is used in the division of stair-cases; and is indispensably necessary to tie in the walls, and to preserve the whole by the shelter of the roof.

In the time of Tarquin the Elder, the Romans channelled their whole town, and inwardly traversed it by many large canals of masonry, which like so many branches of one trunk, terminated in a common conduit, that was arched and accessible to their scavengers, that the foul water of all their houses, at any time, might be discharged into the Tiber. But the greatest emulation of the Roman wealthy citizens was to bring wholesome water into Rome, for the service of the people; to erect very spacious buildings, where their youth might strengthen their constitution by bodily exercise; to build large porticoes,

adorned with statues, where the people might at any time find shelter, when they were to make any purchases, or to study the monuments and history of their own country.

Vallarpandis asserts, that Solomon was the first that reduced architecture to any tolerable order; and that the Tyrians employed by that prince in building the Temple learned the art from him, and carried it afterward into their own country: and to what pitch of magnificence and grandeur the Tyrians carried it before it reached the Greeks, may be learned from Isaiah xxiii. 8. Yet, according to the common account, architecture should be almost wholly of Grecian original: three of the regular orders, or methods of buildings, being denominated from them, viz. Corinthian, Doric, and Ionic, and scarce a single member, or moulding, but what comes to us with a Greek name. The Romans were ignorant of any other order besides the Tuscan, till they received them from the Greeks; nor did they appear till then to have any other idea of the grandeur and beauty of edifices, but what arose from their magnitude and strength. Various have been the ebbs and flowings of architecture since the time of Augustus, when it was reckoned in its glory. Apollodorus, by the encouragement of the emperor Trajan, raised the famous and much admired Trajan's column, which subsists to this time, as an example to shew to what perfection architecture was arrived at that time. However, it now began to dwindle; nor was Alexander Severus, who took great delight in this art, able to support it; for it fell with the western empire, and was not retrieved for the space of twelve centuries.

In the fifth century, all the beautiful monuments of antiquity were destroyed by the Visigoths; and architecture from that time became coarse and artless, till the time of Charlemagne, who used his utmost endeavours to restore it; as likewise did the French with some success, by the encouragement of Hugh Capet, and his son Robert, who continued to prosecute his design.

In the thirteenth and fourteenth century, the beauty of architecture consisted wholly in a multitude of ornaments, and great delicacy, though frequently all their solicitude and care was without conduct or taste.

During the two last centuries the modern architects have used their utmost efforts to reinstate the primitive simplicity and beauty of ancient architecture; so that all our grand and public edifices are built after the manner of the antique, and some of them not far inferior to those celebrated structures.

Architecture is commonly divided in three parts, viz. civil, military, and naval.

Civil ARCHITECTURE is the art of contriving and executing commodious buildings for the use of society,

society, and the conveniency of civil life. In this part our chief regard should attend to conveniency, strength, beauty, decorum, and æconomy. The conveniency is the matter principally to be considered in the plan of a building, so to order the parts thereof, that they may answer the intention of the work, and not embarrass one another. The strength depends on the choice and goodness of the materials, and upon the solidity of the foundation, the squaring, levelling, and plumbing of the walls, &c. and a due attention of the bearings of every part. The beauty, in an exact order or symmetry, which should be observed in every part, so that one member does not exceed its proportion in regard to another member, and that when complete, they should altogether exhibit an agreeable form and appearance. Decorum teaches the architect to have a regard to design, custom, and nature: and æconomy, to consider the expence, in order to regulate the form and manner of the design.

Vitruvius, among all the ancients, is the only entire author on architecture: he composed ten books on that subject, which he dedicated to Augustus, in whose time he lived. Besides him, Baptista, Alberti, Palladio, Scamozzi, Blondel, Goldman, Perrault, Walton, Sturmius, and Wolfius, are celebrated for writing on architecture.

Military ARCHITECTURE instructs us in the method of fortifying cities, camps, sea-ports, &c. See FORTIFICATION.

Naval ARCHITECTURE is the art of fabricating the hull or lower frame of a ship; distinct from the superstructure that comprehends her machinery and furniture for sailing; which last, we shall explain under the articles, MAST, SAILS, and RIGGING.

To whom the world is indebted for the invention of ships is, like all other things of equal antiquity, uncertain: if we listen to the fables of the poets, we shall be extremely divided in our opinion amongst the variety of competitors. Prometheus, Neptune, Janus, Atlas, Hercules, Jason, Danaus, Erythraeus, &c. appear with sufficient authority to claim our assent: but Minerva, the auspicious parent of arts and sciences, seems to have a superior title, and to her, probably with more propriety, it has been attributed by fame.

But some who reject these fabulous traditions, and pretend to greater certainty in their allegations, ascribe it to the inhabitants of some places that border on the sea, and seem appropriated by nature for harbouring ships, such as the Phœnicians, Aeginians, &c. This difference of opinions appears naturally to have arisen, on observing the various places where navigation was first practised, or from the different construction and equipage of ships; some of which having been built by the

above-mentioned persons, have entitled them to the whole invention.

A very small portion of art or contrivance was seen in the first ships; they were neither strong nor durable, but consisted only of a few planks laid together, without beauty or ornament, and just so compacted as to keep out the water. In some places they were only the hulks or stocks of trees hollowed, and then consisted only of one piece of timber; nor was wood alone applied to this use, but any other buoyant materials, as the Egyptian reed papyrus, or leather, of which the primitive ships were frequently composed; the bottom and sides being extended on a frame of thin battens or scantlings, of flexible wood, or begirt with wickers, such as we have frequently beheld amongst the American savages ourselves. In this manner they were often navigated upon the rivers of Ethiopia, Egypt, and Sabæan Arabia, even in later times. But in the first of them, we find no mention of any thing but leather or hides sewed together. In a vessel of this kind, Dardanus secured his retreat to the country afterwards called Troas, when he was compelled by a terrible deluge, to forsake his former habitation of Samothrace. According to Virgil, Charon's infernal boat was of the same composition.

But as the other arts extended their influence, naval architecture likewise began to emerge from the gloom of ignorance and barbarism; and as the ships of those ages were increased in bulk, and better proportioned for commerce, the appearance of those floating citadels of unusual form, full of living men, flying with seemingly expanded wings, over the surface of the untraveller'd ocean, struck the ignorant people with terror and astonishment: and hence, as we are told by Aristophanes, arose the fable of Perseus flying to the Gorgons, who was actually carried thither in a ship! Hence, in all probability, the famous story of Triptolemus riding on a winged dragon is deduced, only because he sailed from Athens, in the time of a great dearth, to a more plentiful country, to supply the necessities of his people. The fiction of the flying horse Pegasus may be joined with these, who, as several mythologists report, was nothing but a ship with sails, and thence said to be the offspring of Neptune, the sovereign of the sea: nor does there appear any other foundation for the stories of griffons, or of ships transformed into birds and fishes, which we so often meet with in the ancient poets. So acceptable to the first ages of the world were inventions of this nature, that whoever made any improvements in navigation, or naval architecture, building new ships better fitted for strength or swiftness than those used before, or rendered the old more commodious by additional contrivances, or discovered countries unknown to former travellers,

lers, were thought worthy of the greatest honours, and often associated into the number of their deified heroes; hence we have in astronomy the signs of Aries and Taurus, which were no other than two ships, the former transported Phryxus from Greece to Colchos, and the latter Europa from Phœnicia to Crete. Argo, Pegafus, and Perseus's whale, were likewise new ships of a different sort from the former, which, being greatly admired by the barbarous and uninstruited people of those times, were translated amongst the stars, in commemoration of their inventors, and metamorphosed into constellations by the poets of their own and of succeeding ages.

Originally all ships, for whatever use designed, appear to have been of the same form; but the various purposes of navigation soon occasioned a considerable difference, in their size, construction, and equipage, at which time they became chiefly characterized as vessels of war, burthen, or passage.

The ships of war of the ancients were distinguished from other kinds of vessels, by various turrets and accessions of building, some to defend their own soldiers, and others to annoy the enemy; and from one another, in later ages, by several degrees or ranks of oars, the most usual number of which was four or five, which appear not to have been arranged, as some imagine, on the same level in different parts of the ship; nor yet, as others have supposed, directly above one another's heads; but their seats being placed one behind another, ascended gradually like stairs. Ptolemy Philopater, urged by a vain-glorious desire of exceeding all the world besides in naval architecture, is said to have farther enlarged the number of banks to forty, and the ship being otherwise in equal proportion, this raised her to such an enormous bulk, that she appeared at a distance like a floating mountain or island, and, upon a nearer view, like a prodigious castle on the ocean: she contained four thousand rowers, four hundred sailors employed in other services, and near three thousand soldiers. But this, and all such monstrous fabrics, served only for shew and ostentation, being rendered by their vast bulk unwieldy and unfit for service. Athenæus informs us, the common names they were known by, were Cyclades, or Aetna, i. e. islands, or mountains, to which they seemed nearly equal in bigness; consisting, as some report, of as many materials as would have composed fifty triremes, or ships of three banks. Thus much we thought necessary to say concerning the naval architecture of the antients; for the several ornaments, furniture, and instruments of war, see Scheffer, or Potter's *Antiq. b. ii. c. 14, 15, 16, &c.* To this we shall add, a general sketch of the art, as it has been improved by the mo-

derns, and appears at this day. See NAVIGATION, SHIP.

Naval architecture then may be comprehended in three principal articles. 1. To give the ship such a figure, or outward form, as may be most suitable to the service for which she is intended. 2. To find the exact shape of all the pieces of timber necessary to compose such a fabric. 3. To make convenient apartments for the artillery, ammunition, provisions, and cargo, together with suitable accommodations for the officers and men.

In order to give the bottom a proper figure, and the qualities necessary to make her answer the service for which she is designed should be considered. A ship for the merchant's service should stow her cargo well: and be so fashioned as to go well, carry a good fail, steer easily, and lie in a high sea, without straining.

Some eminent geométricians have endeavoured to discover the form of a solid that will answer all these purposes best, or meet with the least resistance in dividing the fluid through which it is to pass; but have not been able to reduce their theory to practice, on account of the various situations in which a ship is obliged to lie when under sail. The artificers thus despairing to establish this point by mathematical rules, have applied themselves entirely to experience and observation, which may greatly supply the deficiency of art; but though they may discover that a ship has bad qualities, it may be difficult to determine where they lie, or whether they are in the hull or rigging; but if their observations be aided by mathematical principles, it will certainly conduce very much to attain the desired end. See EVOLUTION, TRIM, SAILING.

But as many ships have been built, which seem to answer every purpose for which they were calculated, some builders have studied chiefly to copy those which are approved by the seamen; and this method they very improperly regard as the principal rule to be observed in building. Now as the bodies of ships are very different, there are of course variety of different models adopted as standards. But admitting a possibility to discover such a body as should give entire satisfaction, and have every good quality requisite for the service proposed, yet this could, by no means, be established as a standard for ships of a different size to be copied from, since although we may have a first rate of 100 guns, which has been found by experience to be a very good ship in every respect; yet, we should be much deceived to build a 20 gun-ship, in which all the parts bore a similar proportion to one another, which they have in the first rate.

It has been remarked above, that a ship of war must carry her lowest tier of cannon high enough above

above the water, otherwise a great ship which cannot open her lower battery, when sailing with a fresh side wind, may be taken by a small one that can make use of her cannon.

A ship should be duly poised, so as not to dive or pitch heavily, but go smooth and easy through the water, rising to the waves when they run high, and the ship has reduced her fail to the storm; otherwise they will break aboard and strain the decks, or carry away the boats: the masts are likewise in great danger from the same cause.

A ship should sail well when large and before the wind, but chiefly close hauled, or with a side wind, and her sails sharp trimmed, and then not fall off to the leeward.

Now the great difficulty consists in uniting so many different qualities in one ship, which seems to be nearly impossible; the whole art therefore is to form the body in such a manner, that none of these qualities shall be entirely destroyed, and in giving the preference to that which is chiefly required in the particular service for which the vessel is built; but as it would protract the article to a very extraordinary length, to illustrate this point in every circumstance, we shall only observe, that it is possible so to unite them all in one vessel, that each of them may be easily discerned. When it happens otherwise, the fault must lie in the builder, who has not applied himself to study the fundamental rules and principles of his art. For a more circumstantial account, we refer the reader to Du Hamel's *Elem. Nav. Architect.* to Bouguer's *Traité du Navire*; and the English reader, to Murray's *Treatise on Ship-building and Navigation*.

But, if we except some ancient artificers possessed of a natural genius, and a few of the moderns who have been instructed in the principles of geometry, and have laboured hard to make a progress in ship-building, we may venture to assert that the greatest number satisfy themselves with copying ships that are esteemed good sailors; and a tenacious imitation of these servile mechanical methods, which are too common, have, to the great reproach of the art, produced all these pretended rules of proportion; for the various models they have hitherto used prove beyond dispute that they have not yet found a proper standard: the only reason why they have tried so many different methods, is because they could not find the best; yet every builder confines these mechanical rules of describing the midship-frame, and forming the rest of the timbers, to his own fancy, and concealing it from the inferior artificers, who may be possessed of a genius and taste greatly superior to his own; but we would inform these gentlemen that this is ever regarded by the polite world as a certain characteristic of a narrow and vulgar education, a sordid and illiberal disposition, and a perverse and crooked taste!

Who ever heard, that a great architect endeavoured to conceal the proportions of the different orders of architecture? Do we not see every where systems of that noble art published, plans, elevations, and sections, presented to the general observation of mankind for their approbation or censure? But possibly, we are afraid that publication of ship-building may be dangerous in a political light, by making our enemies masters of the secret. This can never be the case, since we know that our seventy-gun ships and frigates, generally esteemed the most useful ships in the navy, have been all the late war entirely copied from the models of the French, who have never studied to conceal them. But although the methods of describing the midship-frame, and forming the rest of the timbers, be known to most of our younger artificers, yet we have but few good master-builders; this requires a greater portion of genius, than the mere mechanical methods. They should, at least, have a sufficient acquaintance with mathematics, physics, mechanics, and the nature of solids and fluids, to be able to discover what figure would procure some good quality, without hazarding the putting a bad one in its place. We shall give some account of the principal pieces that compose a ship, and illustrate the affair by a plate, referred to from the article *SHIP-BUILDING*.

Counterfeit ARCHITECTURE, is that which consists of projections painted either in claro or oscuro, or in colours imitating marble.

ARCHITECTURE, in perspective, is a building wherein the members are of different diameters or modules, and diminish in proportion to their distance, in order to make the edifice or structure, appear longer to the eye than it really is.

ARCHITRAVE, in architecture, is that part of the order of columns lying immediately upon the capital. It has its name from representing the principal beam or portrait in any building; it is likewise called the reason-piece, or master-beam, in timber building; but in chimnies it is called the mantle-piece; and over the jambs of doors, and the lintels of windows, hyperthyron.

ARCHIVAULT, in architecture, the inner center of an arch, or a ligature adorned with moulding, running over the fronts of the arch stone, and bearing upon the imposts. It has only one face in the Tuscan order, two in the Doric and Ionic crowned, and in the Corinthian and Composite, the same moulding with the architrave.

ARCHIVE, or *ARCHIVES*, an apartment in which records, charters, and other papers of a state or community are deposited.

The word is formed from the Latin, *area*, a chest.

ARCHMARSHAL, the grand marshal of the empire; a dignity belonging to the elector of Saxony.

ARCHON,

ARCHON, in antiquity, the chief magistrate of Athens, after the abolishing of monarchical government. It was also an appellation given to several officers, both civil and religious, under the Greek emperors.

The word is Greek, *αρχων*, and literally signifies a governor or commander.

ARCHONTICS, the name of a sect of heretics, who were a branch of the Valentinians. They attributed the creation of the world to different angels; neglected baptism, and all the mysteries of faith; said that women were the work of the devil; and denied the resurrection of the body.

ARCHPRIOR, a name by which the master of the order of the knights-templars was sometimes called.

ARCHTREASURER, the grand treasurer of the German empire; a dignity belonging to the duke of Brunswick, king of Great Britain. It is also claimed by the elector palatine.

ARCTIC, or **ARTIC**, in astronomy, an epithet applied to the north pole; likewise to a lesser circle, parallel to the equator, at $23\frac{1}{2}$ distance from the north pole. See **SPHERE**, **POLE**, **CIRCLE**, &c.

ARCTIUM, burdock, in botany, a genus of plants which produces large heart-shaped leaves growing on foot stalks, that arise from the roots, which are large, biennial, and run perpendicular in the ground; the flower is composed of many uniform tubulated florets, containing five short filaments with cylindrical antheræ; the germen is oblong, with a hairy top supporting a slender style, and becomes a single pyramidal angular seed, crowned with down. These plants grow wild in many parts of England; the leaves are used by some for burns and inflammatory tumors; the seeds are esteemed extremely diuretic, and are reckoned effectual in carrying off by those discharges, what is very much the occasion of arthritic pains, when it is once deposited upon the joints. The burdock is called lappa by Tournefort and others, also by some bardana; but Linnæus has altered it to arctium, so called originally by Dioscorides.

ARCTOPHILAX, in astronomy, the name of a constellation, otherwise called Boötes. See **BOÖTES**.

ARCTOTIS, in botany, a genus of plants with radiated flowers, formerly called anemonespermus.

ARCTURUS, in astronomy, the name of a fixed star, of the first magnitude, in the skirts of the constellation Boötes: for its declination, right ascension, &c. See the constellation **BOÖTES**.

ARCTUS, in astronomy, the Greek name of *ursa major* and *minor*, northern constellations.

ARCUATION, in gardening, is the act of propagating trees, shrubs, &c. by laying down in the

earth, and fastening with pegs, the branches of a stool or mother plant, in order to their striking root, and thereby becoming plants themselves. In some sorts it is necessary to cut a notch in the joint about half-way through, to facilitate their rooting; but others, whose parts are more inclinable to rooting, does not require it. If the main branches are so stubborn as not easily to bend, it may be proper to cut them half-way through, with a slit upwards, which will make them more pliable. Some sorts require to be layed two years, before they get root, which by trying one or two may be known; they all should have the earth drawn in a little ridge about the extremity of the layers, in order to retain the moisture when watered in dry weather.

ARCUTIO, the name of a machine consisting of a board covered with hoops, and used by the nurses of Florence, to prevent the child from being overlaid. Every nurse is obliged to lay her child in an arcutio, under pain of excommunication.

ARDASSES, in commerce, the coarsest of all the silks brought from Persia.

ARDEA, the heron, in natural history, a genus of long-beaked birds; distinguished from all others by having the middle toe of each foot serrated, or jagged, with a series of scales on its outer side.

ARDENT, something hot, or as it were burning.

The word is formed from the Latin, *ardens*, which is derived from *ardere*, to burn.

ARDENT Fever, a violent burning fever. See **FEVER**.

ARDENT Spirits, those distilled from fermented vegetables; so called because they easily take fire and burn.

ARDERS, among husbandmen, implies the followings or plowings of grounds. See **FALLOWING**.

ARDO VENTRICULI, the cardialgia, or heart-burn. See **CARDIALGIA**.

AREA, in a general sense, implies any plain surface whereon we walk, &c.

The word is Latin, and properly signifies a threshing-floor.

AREA, in geometry, signifies the superficial content of any figure whatsoever. To find the area or content of any figure, see for each under its respective name.

AREA, in astronomy, is described by the radius vector, or line joining the sun and planet in its orbit, at different periods of its revolution; and these areas are always proportionable to the time in which they are described; thus (Plate X. fig. 1.) the area of the triangle $A n S$: area of the triangle $n S P$: :: the line of the planet's describing the arch $A n$ of its orbit, to the time of describing the arch $n P$ of its orbit.

AREA,

Fig. 1. Argument of Latitude

Fig. 2. Assay Oven

*Fig. 3.
Athanor*

AREA, among physicians, the same with alopecia. See ALOPECIA.

ARECA, in botany, a species of the palm-tree growing in the East-Indies, producing male and female tripetalous flowers, with egg-shaped seeds. It is accounted by the natives of those parts, as a stomachic and preserver of the gums.

ARENA, sand, in natural history. See SAND.

ARENA, in antiquity, the place where the gladiators, &c. fought; so called from its being always covered with sand to conceal the blood spilt in the combat from the view of the people.

ARENATION, a kind of dry bath, where the patient sits with his bare feet on hot sand.

ARENARIA, in botany, a genus of decandrious plants, whose flowers are composed of a pentaphyllous empalement, with five ovated petals, and ten awl-shaped filaments, topped with roundish antheræ; the germen is egg-shaped, supporting three styles; the capsule, which is unilocular and ovated, contains several reniform seeds.

AREOLA, among anatomists, the coloured circle surrounding the nipple of the breast.

AREOPAGUS, or ARÆOPAGUS, in antiquity, a sovereign court at Athens, so famous for the justice and impartiality of its decrees, that the gods themselves are said to have submitted their disputes to its determination.

ARGEA, or ARGEI, in antiquity, thirty human figures made of rushes, and thrown annually by the priests or vestals into the Tiber, on the day of the ides of May.

ARGEMONE, the prickly poppy, in botany, a plant which is common in most parts of the West-Indies; the flower it produces is polyandrious, containing five roundish petals, which spread open; the capsule is quintangular and egg-shaped, and filled with a number of small seeds. It is called by the Spaniards, *fico del inferno*, or devil's fig.

ARGENT, in heraldry, the white colour in the coats of gentlemen, knights, and baronets; the white in the arms of sovereign princes being called luna; and that in the arms of the nobility, pearl.

This is expressed, in engraving, by the parts being left plain, without any stroke from the graver.

ARGENTARIA CRETA, in natural history, an earth, perfectly white and pure, found in Prussia, and greatly esteemed for cleaning plate.

ARGENTINA, in natural history, the name of a fish found in several parts of the Mediterranean. It resembles a pike, and has an oblong round body without scales. It is of a greenish ash-colour above the lateral lines, but below them of a bright shining silver colour, especially over the covers of the gills. The snout is oblong; the mouth of a moderate size, without teeth in the

jaws, though there are six or eight crooked ones near the end of the tongue. The eyes are large, with a silver-coloured iris; and the brain may be seen through the skull. About the middle of the back is a fin, supported by ten rays. The tail is forked; but the principal mark that distinguishes it from all other fish, is the air bladder, which is conical at both ends, and outwardly looks as if covered with polished shining leaf silver. This is made use of to counterfeit pearls. It is often brought to the fish-markets at Rome.

ARGENTINA, silver-weed or wild tansy, in botany. See POTENTILLA.

ARGENTUM, silver, in natural history. See SILVER.

ARGETENAR, in astronomy, a star of the fourth magnitude, on the curve of the river Eridanus. See ERIDANUS.

ARGILLA, clay. See CLAY.

ARGO, in antiquity, a ship or vessel celebrated among the poets, as being that wherein the Argonauts made their expedition.

ARGO Navis, or the ship, in astronomy. See NAVIS.

ARGOL, red tartar. See TARTAR.

ARGONAUTS, in antiquity, a company of illustrious Greeks, who embarked with Jason, in the ship Argo, on an expedition to Colchis, in order to acquire the golden fleece.

ARGUMENT is defined by Cicero to be *ratio probabilis, et idonea ad faciendam fidem*: "A probable and apt reason to gain belief." It is more accurately defined by the logicians, who call it a mean, or middle, which by its connection with the two extremes, connects the extremes with each other. In other words, it is an inference drawn from premises, the truth of which is indisputable, or at least highly probable.

Arguments are distinguished, in relation to the source from which they are drawn, into arguments taken from reason, and arguments taken from authority; in relation to their form, they are distinguished both by rhetoricians and logicians into syllogisms, enthymemes, inductions, or sorites, and dilemmas. See SYLLOGISM, ENTHYME, INDUCTION, &c.

An argument in form is a syllogism, framed according to the rules of logic, to which this kind of argumentation is nearly allied. All rhetoricians since Aristotle say, that the enthymeme is the argument in rhetoric; because it is the form of reasoning most familiar to orators. Rhetoric, according to their definition, being nothing but the art of finding in every subject arguments proper to persuade, they distinguish them into two kinds, in relation to the sources from which they are furnished; viz. intrinsecal, or artificial arguments, and extrinsecal, or natural ones. Intrinsecal, or artificial arguments, called by the Greeks, *ἐνδοχόμενα*, and by the

G g g

Latins,

Latins, *insula*, are those which depend on the ability of the orator, which he either draws from himself, or from his audience, or from the subject on which he is treating. The orator sometimes persuades from the weight of his own person or manners, when his discourse strikes his audience with a lively idea of his virtue and probity; because we voluntarily give credit to the words of such a man, especially in points that are doubtful and problematical: it was for this reason, that Cato regarded probity as the great basis of all eloquence: *Orator vir bonus, dicendi peritus*. The arguments that are drawn from the part of the audience, have for their object some passion or other, that may lead and bias the judgment either to this or that side. It is by this, that the orator is enabled to exercise an absolute empire over those that hear him, and determine their judgement just as he pleases. But to do it effectually is a great and difficult art, as it requires a thorough and deep knowledge of manners and passions, and a perfect acquaintance with all the various springs of the human mind.

The arguments that are drawn from the subject itself, consist in laying it open to the bottom, and considering its nature, circumstances, effects, consequences, conformity, or disagreement with others, &c.

Extrinsical or natural arguments are those which do not depend at all upon the orator, but are found as it were ready made to his hands; such, for instance, are arrests, judgements, laws, written demonstrations, public registers, depositions of witnesses, &c. which supply him with authorities, from which he draws his consequences.

ARGUMENT, in astronomy, is a known arch, by the help of which we find others that are unknown.

Thus if the plane of the planet's orbit be supposed infinitely extended to the heavens, the orbit then respectively to the sun S, (Plate XIII. fig. 1.) will be a great circle, as NpD_b , of the celestial sphere, inclined to the celestial ecliptic NDe ; the intersections or nodes of these two circles will be in N and D; and if the point b , answering to the beginning of aries, be marked on the orbit NpD_b , the arc D_b is then called the longitude of the ascending node: from the point p , draw pl perpendicular to the ecliptic, then is the arc pl the planet's latitude, and Dp the argument of the planet's latitude, which is the planet's distance from the ascending node.

ARGUMENT also implies the abridgement or heads of a book, chapter, poem, &c.

ARGUMENTATION, the act of arguing; and the manner of framing arguments.

ARGUS, in natural history, the name of an uncommon serpent found in Guinea; and so called from its being covered with spots from the head to

the tail, resembling eyes. On the back there is a double row of them, which are the largest, and the ground colour of the scales is a bright chefnut, except on the back between the eyes, where it is of a dark brown.

ARGUS is also the name of a very curious shell, about three inches long, two in diameter, and somewhat less in height. The mouth is wide, and the lips are continued at each extremity in the form of a broad short beak, each way. The general colour is yellowish, only there are three brown bands of a considerable breadth running over it; and the whole surface is adorned with a multitude of round spots, like eyes, from whence it has its name. It is brought from Africa and the East Indies.

ARIA *Theophrasti*. See CRATÆGUS.

ARIANS, in ecclesiastical history, a sect of heretics, who followed the opinions of Arius, a presbyter of Alexandria, in the time of the patriarch Alexander. He broached his heresy in the beginning of the fourth century.

ARIANISM, the doctrines of Arius and his followers. It is a remark not unworthy observation, that the greatest number of those who have dissented from the received opinions of the church, have done it through the disappointments they have met with in the earlier part of life, and have afterwards been confirmed in their errors, by that violent spirit of opposition which is sure to persecute them. We shall be convinced of the truth of this, if we attend a little to the conduct of Arius, when he first published his tenets to the world. He was a sound scholar, and a subtle disputant; as apt in logic, as accomplished in the belles lettres. Under the appearance of extraordinary virtue and piety, he had the art of concealing his vanity and ambition. From being a deacon, he was raised by Achilles, bishop of Alexandria, to the priesthood. At the death of this prelate, which happened in the year 312, Arius expected to have been elected into his room; and was chagrined and disappointed at Alexander's being chosen. He was determined to be revenged on his rival; and accordingly, not only preached against him, but published a book, written expressly against Alexander, wherein he maintained, "That THE WORD was not equal to the Father, and that it had not existed from all eternity; but had been created out of nothing, and of course was to be ranked amongst the number of created beings." This was the first source and origin of that doctrine, which was called afterwards Arianism; and it arose, as we have already seen, from chagrin and disappointment. Alexander proceeded against his antagonist with all the rancour and zeal of a furious bigot; what he wanted in argument he made up in railing, and at last advanced so far as to excommunicate and anathematize him. It must be owned, indeed,

Aries

indeed, that he did this very *canonically*, if not charitably; for he called together near an hundred bishops, amongst whom Arius boldly professed and defended his doctrines. Immediately all the thunder of the church was launched against the poor culprit and his followers; he was called unanimously the Man of Sin, and was very *piously* consigned over to eternal perdition. It was expected by all the orthodox, that this powerful argument, which was so full of reason and religion, would have silenced Arius: but it had a direct contrary effect, for like the oak mentioned by Horace,

*ab ipso
Duxit opes animamque ferro;*

he gained strength and spirits, by being hacked and hewed with the sword of persecution. His doctrines spread like wild-fire throughout Egypt, Lybia, and Palestine; converts came over to him daily, and that very opposition *was for his health, which was intended to him an occasion of falling.* Things now began to wear a very serious aspect; when Constantine the Great convened the General Council of Nice, in the year 325. Before this august assembly Arius presented himself; but to very little purpose for either party, as he was determined to defend his tenets, and the bishops who were met together would not listen to him, but while he was speaking thrust their fingers into their ears. A second anathema was thundered out against him, and he was condemned to banishment; where he continued three years, and was then recalled. He presented at his return a confession of his faith to Constantine, which was drawn up in such a very artful manner, that it comprized both the Catholic doctrine, and that of his own sect. Arius afterwards went to Alexandria, of which see Athanasius was then bishop, but could not continue there, as the people refused to communicate along with him. He died of a fainting fit, at Constantinople, in the year 336: his death has been regarded by some as a judgement, because Alexander had often prayed to God to take him out of the world, or to hinder his heresy from spreading. His being removed out of the world did not seem to answer any great end, and therefore we will suppose it to be natural; for he left his doctrines behind him, which from that day to this, have had a considerable number of followers.

The particular tenets which were held by Arius are, That THE WORD, or the Son, did not exist from all eternity, but was created in time; that he is inferior to the Father, and of a different essence; that Christ had nothing of human nature but merely the flesh, in which was THE WORD, that operated in him, as the soul in us; that the Holy Ghost was of the order of created beings. These tenets made a very considerable progress in the

Eastern churches, and were advanced in the West by the followers of Servetus, who in the year 1531, published a treatise against the mystery of the Trinity. See SERVETISTS.

They were adopted likewise with very little difference by Faustus Socinus, a gentleman of Sienna, about the year 1548, from whom sprang the sect of the Socinians. See SOCINIANS.

These doctrines are all of them confronted in the creed that is called Athanasian; not from its having been composed by Athanasius, for it is of later date; but because it contains those tenets which were supposed to be held by Athanasius, who was a warm stickler against Arius. See ATHANASIAN.

ARIDED, in astronomy, a fixed star of the second magnitude, in the swan's tail. See the constellation CYGNUS.

ARIDAS, a kind of taffety manufactured in the East Indies from a shining thread drawn from certain plants; and hence they are stiled aridas, or herbs.

ARIES, in astronomy, a constellation in the heavens represented by a ram, and which is the first sign of the zodiac. The sun enters this sign the twenty-first of March, at a time when the fields and hills are more numerously overspread with flocks than at any other season, by the new increase of lambs; therefore it is natural to think, that the ancient astronomers observing the sun to enter this sign at so profitable a time, thought fit to signalize it by the principal of the flock, aries, or the ram.

The fabulous stories of the poets concerning aries are as follow: Athamas, king of Thebes, had by his wife Nephele, a son named Phrixus, and a daughter named Helle. He afterwards married again Ino, who fell desperately in love with her son-in-law Phrixus; but finding herself slighted by him, she persuaded Athamas that the death which then happened, could not be remedied but by sacrificing Phrixus and Helle: but Nephele gave them a golden ram, which she had received of Mercury. On this ram they fled through the air from Thebes, and in their flight Helle fell off into the sea, which from thence was called Hellespontus; but Phrixus arrived at Colchis, where he was kindly received by Elia the king, who sacrificed the ram to Jupiter, and hung up the golden fleece in the grove of Mars. There it was kept by bulls with brazen feet breathing fire, and also by a great dragon. The ram was afterwards taken up into heaven for his services, and made a constellation.

Others will have this ram to be that which led Bacchus to a spring of water, when he had like to have perished through thirst in the desert of Lybia. Novidius will have this to be the ram which Abraham offered up instead of his son Isaac.

For the places of the stars in this constellation, see the following Catalogue. See also Plate XIV.

ARIES, the battering ram. See BATTERING RAM.

ARISARIUM, in botany. See ARUM.

ARISH, a Persian long measure, containing about 3107 English feet.

ARISTA, among botanists, a long needle-like beard, which stands out from the hulk of a grain of corn, grass, &c. It is also called awn.

ARISTOCRACY, a form of government where the supreme power is lodged in the principal persons of the state, either on account of their nobility, their capacity, or their probity.

The word is Greek, and compounded of *αρις* principal, and *κρατος*, to command.

ARISTOLOCHIA, *Birthwort*, in botany, a genus of gynandrious plants; the flower consists of an irregular single petal without any filaments, but contains six anthers, which join the under part of the stigma; the fruit is a large hexangular capsule of six cells, containing a number of depressed seeds: there are two sorts of birthwort, whose roots are imported for medicinal uses from France, Spain, and Italy; one fort with long roots, and the other with roundish roots, in shape and colour like the common cyclamen roots. The former is of a subacrid aromatic taste, and both sorts by all accounted a great cleanser of the womb, both as a provoker of the menstrual discharges, and a forwarder of delivery: it is said to be so powerful as to cause abortion, if given to a woman with child; and many of the old writers on physic have asserted, that if a pregnant woman stepped over one of these roots, it would certainly cause a miscarriage, and the roots, properly applied, would hasten delivery.—To birthwort are ascribed some alexipharmic qualities, and it is reckoned detergent externally, and suppurative; for which reason it hath been used in styptic plasters.—One of the species of aristolochia is called the Virginia snake-root. See the article SNAKE-ROOT.

ARISTOTELIAN, in a general sense, signifies any thing that belongs to Aristotle.

ARISTOTELIAN *Philosophy*, the philosophy of Aristotle, called also the peripatetic philosophy, from a custom which Aristotle had to philosophize while he was walking. Notwithstanding Plato was Aristotle's master, the peripatetic philosophy was set up in opposition to the academic, of which Plato was the inventor. Aristotle was chagrined at Zenocrates succeeding Speusippus as head of the academic sect; and thro' a spirit of emulation composed his system of laws and politics, to destroy the credit of what Plato had before written upon that subject.

If we consider the busy life of Aristotle, who was tutor to Alexander the Great, and besides the time which he spent in travelling, was engaged in endless disputes in the Lyceum; we shall be astonished how he could find leisure to compose the hundredth part of those books he is said to have done, amounting to above four thousand, of which few more than twenty are at present extant. The truth is, he was a man of an universal and comprehensive genius, with an insatiable thirst for knowledge, that roused his industry, and made him read over all the books of the ancients. At the head of those works which he has left us, are his treatise of Rhetoric and Poetry, which were composed in all probability to form the taste of that illustrious prince whose education had been committed to his care. They are full of excellent remarks and wise instructions in these two branches of science, and are undoubtedly master-pieces: no man has penetrated farther into the human heart than he has done; nor laid more open those secret and invisible springs that move it. Whatever has been written since on these two subjects has been borrowed from him; and one may venture to affirm that these two works do more honour to his memory, than all the others put together. His *Morals* are dry and barren, and present us with nothing but general views and metaphysical propositions; which are more adapted to set off the wit and burden the memory, than touch the heart and rectify the will. Such is in general the spirit that prevails in the ethics of this philosopher: we shall present the reader with a few of his precepts, and the turn that he gives them:

First, He says, that the happiness of man does not consist either in pleasures, or riches, or honours, or power, or nobility, or in speculations of philosophy; but in—what?—why the *EUTAEKEIA*; a word of so dark and doubtful a signification that Hermolaus Barbarus is said to have consulted the devil about it; after which, in his Paraphrase on Themistius, whether from the devil or himself we will not pretend to say, he renders it by *perfectibilia*, which is not a whit the clearer. We imagine that Aristotle meant *habitudes* of the soul, which render it more or less perfect.

Secondly, "Virtue is full of charms and attractions." This he had from his master Plato; but he

improves upon it, and says, that "a life where the virtues are linked together one with another, must needs be perfectly happy."

Thirdly, Tho' Virtue is sufficient of herself, yet it cannot be denied, that she finds a powerful support in riches, honours, nobleness of blood, beauty, and strength of body; all which contribute to make her take a loftier flight, and, of course, advance the happiness of mankind.

Fourthly; All virtue is placed in the middle, between the two extremes of excess and defect: thus, courage is the mean between fear and rashness; magnificence, betwixt luxury and fordidness, &c. from which one may conclude, that the number of vices is double that of the virtues, because every virtue has a vice on each side of it.

This is sufficient for a specimen of Aristotle's Ethics, in which he has not succeeded so well as in his Logic. He has there laid open the principal sources of the art of reasoning; he has pierced into the inexhaustible fund of human thoughts; he has distinguished ideas; has shewn their connection with each other, and pursued them thro' all their deviations and seeming contrarieties, till at last he has brought them to a fixed and determined point. Yet his method, so much approved by philosophers formerly, is not without defect; sometimes he is too diffuse and prolix, which discourages one from going on with him: his book of Categories, and that of Interpretation may be contracted to a few pages; the idea is often lost in a crowd of words: at other times he is obscure and embarrassed; we are obliged to divine, and can guess only at his meaning. We shall give no specimen here of his Logic, as we shall be obliged, in the course of this work, to explain it under the different words that he has made use of to distinguish his syllogisms, &c.

Let us now a little consider his *Physics*, or natural philosophy; in which we shall generally follow the celebrated Lewis Vissis, as he has disposed it in a very methodical manner. He begins with his eight books of natural principles, which seem rather a compilation of different memoirs, than a work formed upon any one regular plan. These books treat in general of *body extended*, which is the object of physics; and in particular, of the principles, and every thing that has a connexion with them; as motion, space, time, &c. Nothing can be more confused than this part of his work: the definitions render those things which they were intended to explain, less intelligible than they were before. Aristotle begins with blaming the philosophers who preceded him, some for admitting too many principles, others for admitting only one. With regard to himself, he has established three, viz. *Matter*, *Form*, and *Privation*. Matter, according to him, is the general subject on which nature operates; it has existed from eternity, and is itself eternal; it is the parent of all things that long

for motion, and desire that form should unite them to it. It is difficult to say what Aristotle understood by this first matter, which he defines, "that which has neither quality nor quantity, nor any mode or accident by which its essence may be determined." It seems to have been with him a mere abstract idea, or imaginary being that had no real existence of its own, tho' he affirms that it was the first principle of existence in every thing besides.

Having established these three principles, he passes on to explain the causes, which he treats of distinctly enough, but almost without mentioning the first cause, which is God: and this has given occasion to some to accuse Aristotle of atheism, as if he was ignorant of, or did not believe in the existence of a Deity. But this appears to be a mistake; for he asserts that there is ONE effective principle, or plenary cause, by and through which every thing exists; that it informs the whole universe, and renders those beings in which it resides capable of motion or rest in themselves. He calls indeed this first great cause Nature; but he could mean nothing by this term but the Deity, or that ONE SUPREME, in and thro' whom *we live and move, and have our being.*

He then proceeds to treat of motion and rest; finite and infinite; of the vacuum and atoms; of space and time; in all which he makes no confusion; one proposition leads naturally to another, and tho' he proceeds always with the greatest rapidity, yet still the connection is preserved in the strongest and plainest manner imaginable.

After having explained what he means by *Matter* and *Form*, he begins to treat of the third principle, which he calls *Privation*. He contradicts the prevailing opinions that nothing absolutely perished, but something was again produced from it; that all the changes which happen in bodies, were only another arrangement, or different distribution of the parts of matter which compose these same bodies; and that increase and diminution, division and reunion, separation and mixture, would account for all the changes that happen in the universe. He rejects these notions, and establishes the doctrine of generation and corruption, affirming that new beings are continually produced out of the womb of Nature, which perish in their turns; and that from this privation, other beings again exist. This part of Aristotle's system is very perplexed and chimerical, and has led the schoolmen into monstrous absurdities, who have multiplied a number of nonsensical terms, such as *Forma substantialis*, *modi*, &c. which raise no ideas, except those of wrangling and disputation.

Aristotle does not content himself with laying down a general system of natural philosophy, but descends to particulars, and treats of wind, rain, hail, dew, &c. besides which he has given us a his-

tory of animals; which has been highly approved by Mr. Buffon, who himself has treated largely on this subject.

It is no wonder, if we consider every thing, that there should be many false and absurd opinions maintained by this universal philosopher. He asserts that the universe is not equally under the immediate government of God, but that the celestial bodies only are worthy of his care and attention: as to all sublunary things, he thinks them below his notice, and, to use the words of Prior, imagines the Deity

Has fairly left us, human elves,
To cut and shuffle for ourselves,
To stand or walk, to rise or tumble,
As matter and as motion jumble.

Diogenes Laertius tells us, that it was the opinion of Aristotle, that the heavenly bodies only were governed by the Deity, and that the earth and all its inhabitants were regulated and influenced by a kind of sympathy with them. He saw that all sublunary things were subject to changes and vicissitudes, to disasters and evils; which made him conclude that they could not possibly be under the immediate care and providence of an all-wise and gracious Being. Aristotle denied the immortality of the soul, which he looked upon as a particle of the Divinity, which was lent to man on his first appearance upon this theatre, and was to be resumed again into the Divinity, when he made his exit. The false notions which he had framed to himself of motion, led him to believe that the world was eternal: Motion, says he must have been eternal, consequently the world, wherein it exists, must have been so too.

Before we conclude this article, it may not be amiss to present our readers with an ingenious parallel, drawn by father Rapin, between Aristotle and Plato. The qualifications of the mind were extraordinary in both one and the other; they had each of them an elevated genius, capable of the highest and noblest contemplations. The wit of Plato was more elegant and polished, and that of Aristotle more grand and profound. Plato's imagination was lively, copious, fruitful in invention, in ideas, in expression, in figures; he could give a thousand different turns, and place the same subject in a thousand different lights, all striking and agreeable: but still this was often nothing but imagination. Aristotle is harsh and dry, but what he says carries with it the force of reason: his diction, tho' pure, has in it I know not what of austerity; and his natural or affected obscurities disgust and fatigue the reader. In Plato there is a delicacy of thought and expression not to be found in Aristotle, who is natural, simple and even, but at the same time close and nervous. The style of Plato is sublime and elevat-

ed, but loose and diffuse; he says always more than he should; Aristotle does not say enough, but leaves to the reader to supply what is wanting: the one surprizes and dazzles with his sublimity and brightness, the other improves and instructs by his judgment and solidity. Plato seems to have studied chiefly how he should speak, Aristotle how he should think; the latter has given us strength and substance, and the former grace and colour.

ARISTOTELIAN Wheel, rota Aristotelica. See *ROTA*.

ARITHMETIC is the art or science of computation, hath for its subject number, and teaches us to give proper answers to such who demand how many?

Number must have been made use of ever since our first parents had occasion to communicate their ideas to one another, of *so many* or *so much*; and as to the origin of arithmetic, tho' history neither fixes the time nor author, yet in all probability it took its rise with the introduction of commerce, and is therefore of Tyrian invention.

Josephus tells us, the art was carried by Abraham into Egypt; from thence it hath been supposed to be transmitted to the Greeks, who handed it with great improvements to the Romans, and from them it came to us; and as learning advanced in Europe, so likewise did the knowledge of the science of arithmetic, which gradually received great improvements, and is far superior to the ancient, which chiefly consisted in the various division of numbers, as appears from a treatise writ by Nichomachus in the third century, and one of Boethius, which are still extant. But what rendered their operations abstruse and tedious, was their imperfection in notation; for not having any character to supply the place of our cypher, (which were received from the Arabians) their series only extended to nine, while the present method changes the value of numbers in a decuple progression.—Modern arithmetic is divided into different kinds, viz. theoretical, practical, instrumental, numerous, specious, logarithmetical, decimal, dignæmical, tetractical, duodecimal, sexagesimal, &c.

Theoretical ARITHMETIC is the knowledge of the properties and proportions that numbers bear to each other considered abstractedly, with the reasons and demonstrations of the several rules in common arithmetic. The seventh, eighth, and ninth books of Euclid's Elements, where he has delivered the doctrine of proportion, and that of prime numbers, is the oldest extant of this kind; however, since Euclid we have had many treatises on theoretical arithmetic by different authors, as Barlaam the monk, Frater Lucae de Burgo, &c.

Practical ARITHMETIC is that which shews the method of working by numbers, so as may be most useful and expeditious for business. The first entire treatise we have of this kind was given by Nicholas

Tartaglia, a Venetian, in the year 1556, consisting of two books: the first contained the application of *Arithmetic* to civil uses, the latter the grounds of algebra. Stifelius gave some few particulars concerning the application of irrationals in 1544, which are no where else to be found. However, since their time, almost an infinite number of authors have appeared to the publick, viz. Metius, Ramus, Clavius, Buckley, Digges, Record, Cocker, Wingate, Leybourn, Ward, Malcolm, Weston, West, Gordon, Fenning, Dilworth, Fisher, &c.

Instrumental ARITHMETIC is that which is performed with great ease and expedition by means of scales, rules, sectors, Napier's bones, &c. for the method of performing which, see under each particular article, *SCALE*, *RULE*, &c.

Numerous ARITHMETIC is that which gives the calculus of numbers or indeterminate quantities, and is performed by the common numeral, or Arabic characters.

Specious ARITHMETIC. See *ALGEBRA*.

Logarithmetical ARITHMETIC is that which is performed by tables of logarithms; which are artificial numbers in arithmetical progression, which being fitted thereto express the ratios of natural numbers in geometrical progression. See *LOGARITHMS*.

Decimal ARITHMETIC is a very compendious method of performing many calculations in practical arithmetic, especially in interest, annuities, &c. See *DECIMAL FRACTIONS*.

Dyadic, or Bynary ARITHMETIC is that wherein only two figures, viz. unity, or 1, and 0, are used. See *BINARY*.

Tetractyc ARITHMETIC is that only wherein 1, 2, 3, and 0, are used.

Duodecimal ARITHMETIC. See *Duodecimal FRACTIONS*.

Sexagesimal ARITHMETIC. See *Sexagesimal FRACTIONS*.

Political ARITHMETIC is the application of arithmetic to political subjects. See *POLITICAL ARITHMETIC*.

ARITHMETIC of Infinites is the method of summing up a series of numbers consisting of infinite terms. See *SERIES*.

ARITHMETIC of Irrationals and Surds, &c. See *SURDS*, &c.

Universal ARITHMETIC, a name given by Sir Isaac Newton to algebra, or the calculation of quantities in general. Nor did that great man, whose elevated genius and profound penetration seem to have traced all the sciences to their true metaphysical principles, give it this title without sufficient reason.

Common arithmetic has two kinds of principles; the first are general rules, independent of the characters made use of to express numbers; the second are rules which depend upon these characters, and are

are properly called rules of arithmetic. The former contain only the general properties of proportions, and take place universally, be these proportions stated how they will.

Hence it follows, that by noting numbers by general expressions, tho' they do not denote one number more than another, we may form certain rules relative to operations, which may be performed by numbers so expressed. These rules shew the result of one or more operations performed by numbers expressed in a general manner, and in the most simple method; and this result is properly nothing more than an arithmetical operation, expressed in characters, which will vary according to the different arithmetical values we assign the quantities substituted for numbers.

In order to set this idea of algebra in a clearer light, it may not be amiss to mention, in a cursory manner, the four common rules of arithmetic. Addition consists in the adding any numbers proposed into one total, without any other operation. If, for example, it were required to add two dissimilar quantities together, as a and b , we set them down simply $a + b$, the result of which is nothing more than an indication, that if a represents a certain number, and b another, these numbers must be added together. The expression $a + b$ is therefore nothing more than an indication of an arithmetical addition, the sum of which will be different, according to the different arithmetical values assigned to a and b . Suppose it were required to add $5a$ to $3a$, we may write $5a + 3a$; but it is plain that this may be expressed in a more simple manner; viz. $8a$; and consequently the arithmetical operation should be expressed in that manner.

Hence it follows, that addition in algebra expresses the sum or aggregate of several numbers, generally in the most simple manner, and saves the arithmetician as much labour as possible.

In subtraction, the thing is the same; for if it be required to subtract b from a , we write $a - b$; because it is impossible to express this operation in a more simple manner: but should it be required to subtract $3a$ from $5a$, it would be improper to write $5a - 3a$; because, if a had any numerical value, it would occasion the trouble of several arithmetical operations; but simply $2a$, which is more convenient in calculation.

The same thing is true in multiplication and division. If we would multiply $a + b$, by $c + d$, we might write indifferently $a + b \times c + d$, or $ac + bc + ad + bd$; though the first method seems the more proper, because it requires fewer arithmetical operations: in the former there are only two additions and one multiplication necessary; in the latter, three additions and four multiplications. But if it should be required to multiply $5a$ by $3a$, we should write $5a$, and not $5a \times 3a$; because the first has only two arithmetical operations, and the second three. In

the same manner, to multiply $a + b$ by $a - b$, we should write $aa - bb$; because this result would be more commodious than $aa + ab - ab - bb$, and at the same time furnishes a useful theorem, namely, that the product resulting from the sum of two numbers, multiplied by the difference of the same numbers, is equal to the difference of their squares.

In division, instead of writing $\frac{20ab}{5b}$, we should set down simply $4a$; but to express the division of ab by cd , we must write $\frac{ab}{cd}$; because a more simple expression cannot be found.

Hence it is evident that Sir Isaac Newton was in the right to call algebra universal arithmetic; because it exhibits all the general and common rules of every kind of arithmetic, in a more clear, concise, and simple method.

But it may be asked, why we should have recourse to perplexity? In all arithmetical questions the numbers are expressed; of what use therefore can it be to give them a literal expression?

The answer is very easy: There are questions far more complicated; and in the solution of these we are obliged to form combinations, of which the number or numbers sought must form a part. We must therefore be possessed of an art, whereby we may represent these combinations without knowing the number sought; and consequently express these numbers by characters not numerical: because it would be very improper and inconvenient to express an unknown number by a numerical character, which we had no reason to expect would be its real value.

ARITHMETICAL, something belonging to, or performed by arithmetic.

ARITHMETICAL Complement of a Logarithm, is what any logarithm wants of 10,0000000, as 7,520335 is the arithmetical complement of 2,4789665, where each figure is subtracted from 9, except the last which is subtracted from 10.

ARITHME- TICAL	- { Mean. Progression. Proportion. Ratio. }	See { MEAN. PROGRESSION. PROPORTION. RATIO. }
-------------------	--	--

ARITHMOMANCY, a species of divination performed by numbers.

The word is Greek, *αριθμομαντια*, and compounded of *αριθμος*, number, and *μαντια*, divination.

ARK, ARC, or ARCH. See the article ARCH. ARK of Noah was a kind of floating vessel, built by the command of God, for the preservation of the several species of animals, at the general deluge. It is derived from the Latin word *Arca*, which signifies a chest or coffer.

As historians and commentators differ widely in their opinions concerning this surprising vessel, we shall lay before our readers what appears to us most worthy

worthy of their attention, in relation to the following particulars, viz. the time that it took in building, the materials of which it consisted, its form, capacity, and resting-place after the Flood.

It is generally agreed that Noah began to build the ark in the year of the world 1557; but it is not so clear at what particular period it was finished. Some have conjectured that he was an hundred and twenty years about it: they are led to this opinion by the following passage in Genesis, where God says, "My spirit shall not always strive with man; his days shall be an hundred and twenty years." Others imagine that it was completed in seventy-eight years; some have assigned a much shorter period, namely, seven or eight years; the Mahometans say that he had only two years allowed him for this work. But all this is only conjecture, and it seems to be impossible to fix the exact time that it took in building; thus much, however, may be collected from the sacred writings, that it was built some time in the fifth and sixth hundredth year of Noah; for God, when he commanded him to build the ark, told him that he and his wife, and his sons, and his sons wives should enter into the ark. Now Noah's three sons, Shem, Ham, and Japheth, were not born till after Noah was five hundred years old, and it is clear that the deluge happened in the six hundredth year of Noah; from which it necessarily follows, that the ark must have been constructed some time between the fifth and six hundredth year of Noah.

As to the materials, the scripture tells us that it was made of *gopher wood*, which is translated by the Septuagint *square pieces of wood*. Some commentators are of opinion that it was cedar, others box, others pine, and others cypress. It is translated by Jerom in one place *ligna levigata*, or *wood that is planed*, and in another *ligna bituminata*, or *wood that is pitched*. Some have maintained that the Hebrew word גפר, *gopher*, signifies any kind of pitchy resinous wood, which is not improbable, as the word גפרית, *gophrit*, literally means *bitumen*, sulphur, or any other inflammable substance. Our learned commentator Mr. Fuller has observed, that the wood whereof the ark was built, was nothing else but that which the Greeks called *κυπαρισσος*, or the Cypress tree; for taking away the termination, cupar and gopher differ very little in sound. Bochart has confirmed this observation, and shewn that no place abounds so much with this kind of wood, as the country about Babylon; near which place Noah is generally supposed to have constructed his ark. Pelletier prefers cedar, on account of its incorruptibility, and the great plenty of it in Asia; whence Herodotus and Theophrastus relate, that the kings of Egypt and Syria built whole fleets of it, instead of pine; and the common tradition throughout the East imports, that the ark is preserved entire to this day on Mount Ararat.

There have not been less various opinions about the particular form of the ark, than about the particular kind of wood of which it was constructed. God commanded Noah to make it three hundred cubits in length, fifty cubits in breadth, and thirty cubits in height. Now the exact dimensions of it might be known to a tittle, if it was only once agreed what the particular measure of this cubit was. But the misfortune of it is, that scarce two people are of the same opinion as to this point, and therefore it is not to be wondered at if they differ widely in every other. Origen thinks that this cubit was of the same dimensions with six common cubits; but the ark in this case must have been monstrously too large, as it would have taken up near the space of a mile. Others have imagined that it was a geometrical cubit, and contained six feet: but the most probable opinion is, that it was the common Egyptian cubit, which was made use of by the Jews from the time of their departure out of Egypt, till the Babylonish captivity. This cubit was pretty near a foot and a half, or twenty-inches and a half of our measure. According to this computation, the length of the ark must have been 512 feet 6 inches; its breadth 85 feet 5 inches; and its height 51 feet 3 inches: its whole capacity consequently would have been pretty nearly 229822 feet 4 inches. Such a building as this would have contained sufficient room for all the creatures that were to enter into it; as we shall clearly conceive, if we consider that the number is not so great, as might at first have been imagined. We are not acquainted with above a hundred and thirty species of quadrupedes; nor do we know of a greater number of birds; and with regard to reptiles not above thirty species. Bishop Wilkins has endeavoured to shew that not above seventy-two of the quadrupede kind needed a place in the ark.

There are various conjectures about the particular manner in which the ark was laid out. Noah was commanded by God to make it with lower, second, and third stories. The lower story was most probably defined for the beasts, the middle for the food, and all the upper for the birds, with Noah and his family. Each story was divided into different apartments, stalls, &c. Drexelius makes three hundred apartments; father Fournier three hundred and thirty-three: the anonymous author of the Questions on Genesis four hundred; Butes, Temporarius, Arias Montanus, Hostas, Wilkins, Lamy, and others, suppose as many different partitions, as there were different sorts of animals. Pelletier makes only seventy-two, namely, thirty-six for the birds, and as many for the beasts: his reason is, that if we suppose a greater number, as three hundred thirty-three, or four hundred; each of the eight persons in the ark must have had thirty-seven, forty-one, or fifty stalls to attend and cleanse daily, which he thinks impossible. But there does

not seem to be much in this: for to diminish the number of stalls, without diminishing the number of the animals, would be insignificant; it being, perhaps, more difficult to take care of three hundred animals in seventy-three stalls, than in three hundred.

Some persons have computed that all the animals contained in the ark could not be equal to five hundred horses; nay, they have reduced the whole to the dimensions of fifty-six pair of oxen. Father Lamy enlarges it to sixty-four pair, or an hundred and twenty-eight oxen: so that supposing one ox equal to two horses, if the ark had room for two hundred fifty-six horses, there must have been room for all the animals. But the same author demonstrates that one floor would suffice for five hundred horses, allowing nine square feet to an horse.

Bishop Wilkins computes all the carnivorous animals equivalent, as to the bulk of their bodies and their food, to twenty-seven wolves; and all the rest to two hundred and eighty bees. For the former he allows 1825 sheep, and for the latter 109500 cubits of hay; all which would be easily contained in the two first stories, and a deal of room to spare.—As to the third story, no body doubts of its being sufficient for the fowls, with Noah, his sons, and daughters. The learned bishop remarks, that the most expert mathematician, even at this day, could not have assigned the proportions of a vessel better accommodated to the purpose, than was this of Noah's; and concludes in the following words; "The capacity of the ark, which has been made an objection against scripture, ought to be esteemed a confirmation of its divine authority; since, in those ruder ages, men being less versed in arts of philosophy, were more obnoxious to vulgar prejudices than now: so that, had it been an human invention, it would have been contrived according to those wild apprehensions which arise from a confused and general idea of things; as much too big as it has been represented too little."

According to the sacred historian, the ark rested in the seventh month, on the seventeenth day of the month, upon the mountains of Ararat. This is a famous mountain in Armenia, situated twelve leagues east of Erivan, in a vast plain, having no other mountain near it on any side. It is called by many of the Eastern nations Ar dag, or Parmardagh, because it stands upright by itself, like a finger when held up. It is so high as to be seen at the distance of ten days journey, according to the stages of the caravans. The city of Tauris is situated near this mountain. Tavernier says that there are many monasteries upon Mount Ararat; and that the Armenians call it Mere Souffar, because the ark stopt here. It is as it were taken off from the other mountains of Armenia, which make a long

chain, and from the middle to the top of it is covered with snow for three or four months in the year. Notwithstanding all this, there are some authors of opinion that the ark rested on a mountain near Apamea in Phrygia.

ARK of the Covenant, in scripture, denotes a small chest or coffer, three feet nine inches in length, two feet three inches in breadth, and the same in height; in which were contained the golden pot that had manna, and Aaron's rod, together with the tables of the covenant, as well the broken ones (according to the rabbins) as the whole. This coffer was made of shittim wood, and was covered with the mercy-seat, which was of solid gold; at the two ends whereof were two cherubims, looking towards each other with expanded wings, which embracing the whole circumference of the mercy-seat, met on each side in the middle. Here it was that the shecchinah, or divine presence rested, both in the tabernacle and in the temple, and was visibly seen in the appearance of a cloud over it: and from hence the divine oracles were delivered in an audible voice, as often as God was consulted in behalf of his people. Hence it is that God is said in scripture to dwell between the cherubims on the mercy-seat because there was the seat or the throne of the appearance of his glory among them. And for this reason the high-priest appeared before the mercy-seat once every year, on the great day of expiation, at which time he was to make his nearest approach to the divine presence, to mediate and make atonement for the sins of the people.

ARM, *Brachium*, a part of the human body, terminating at one end in the shoulder, and at the other in the hand.

Anatomists divide the arm into two parts, calling only that part the arm included between the shoulder and the elbow; the rest they term the forearm. The arm in this acceptation has only one large bone called the os humeri, or the shoulder-bone. The other part consists of two bones, termed the radius, and the cubitus, or ulna.

The os humeri has five sorts of motions, which are effected by five pairs of muscles; upwards by the deltoides, supraspinatus, and coraco-brachialis; downwards by the rotundus major, and latissimus dorsi; forwards by the pectoralis; and backwards by the infraspinatus.

The muscle of the fore-arm are the biceps, brachialis internus, gemellus, brachialis externus, anconeus, pronator, radii teres et quadratus, supinator longus et brevis. Its motions are confined to two kinds, that of rotation, and that of flexion and extension.

ARM, among sportsmen, is applied to a horse, when by pressing down his head, he endeavours to defend himself against the bit, to prevent his being checked by it.

ARM, in geography, implies a branch of the sea running some distance into the land.

ARM of a *Magnet* is a small piece of steel in the iron inclosure, in which the load-stone is placed. See MAGNET.

ARMADILLO, in natural history, the name of an animal resembling a hedge-hog, and almost of the same size. His head, body, and tail, are covered with a shield of a bony substance, and very curiously contrived with most beautiful scales. Near the hind part of the head are two joints, that he may move his head; and on the back seven divisions, or shields, with a yellow skin between each. The feet are also covered with a thinner shield. The lower parts of his body are without this covering, but are beset with hairs near an inch long, which proceed from prominent pores. There are also a few hairs on the skin, which joins to several shells of the shield, like the former; as also near the mouth and eyes.

The head is like a hog, with a sharp snout: it has little eyes sunk deep in the head, and a pointed narrow tongue. The ears are naked, brown, and short; the teeth are of a middle size, and eighteen in each jaw. The feet resemble hands, with five fingers, and roundish nails. He roots up the ground with his snout, like a hog; and is tintured all over with a reddish colour. The tail at the root is near four inches thick; but grows less gradually to the end, which terminates in a point. He lives upon melons, potatoes, and other roots; and will eat flesh when he can get it. He generally lies hid in the ground, and sometimes will frequent water and watery places, where he feeds upon worms, small fish, and water insects. Sometimes he will eat ants, apples, and the berries of certain trees.

ARMED Ship, in the marine, a vessel taken into the service of the government, and equipped by them in the time of war, being furnished with artillery, ammunition, and martial instruments: they are commanded by an officer who has the rank of master and commander in the navy, and are upon the same establishment with sloops of war, having a lieutenant, master, purser, surgeon, &c.

ARMENICA, apricot, in botany. See APRICOT.

ARMENIANS, in ecclesiastical history, a sect or division among the eastern Christians, so called from Armenia, the country which they originally inhabited. There are two sorts of Armenians, the one catholic and subject to the pope, having a patriarch in Persia, and another in Poland: the other are sectaries, and are generally accused of being Monophysites, i. e. of admitting only one nature in Christ. They likewise have two patriarchs, one in the convent of Etchmiazin, near Erivan, a city of Armenia, subject to the king of Persia; and the other at Cis, in Cilicia, subject to the Grand Signior.

The Armenians agree with the Greeks, except in this, that they mix no water with their wine in the eucharist, and use unleavened bread after the manner of the Latins. They abstain in the most rigid manner from eating blood, and things strangled, and are greatly addicted to fasting; inasmuch that, to hear them talk, one would conclude their religion consisted in nothing else.

ARMILLA-MEMBROSA, in anatomy, is that circular ligament which comprehends all the tendons belonging to the whole hand within a circle, in the region of the carpus.

ARMILLARY, in a general sense, implies something composed of rings or circles.

The word is Latin, *armillaris*, and derived from *armilla*, a bracelet.

ARMILLARY Sphere, an artificial sphere composed of a number of circles of the mundane sphere, put together in their natural order, to ease and assist the imagination, in conceiving the constitution of the heavens, and the motions of the celestial bodies. See Plate IV. fig. 6.

The armillary sphere revolves upon its axis within a silvered horizon, which is divided into degrees, and moveable every way upon a brass supporter. The other parts are the equinoctial, zodiac, meridian, the two tropics, and the two polar circles.

ARMINIANS, in ecclesiastical history, sometimes called REMONSTRANTS, are a religious sect or party, who took their name from Arminius, their leader and advocate. They first of all sprang up in Holland, by a separation from the Calvinists; whose catechisms and formulas of faith they rejected and ridiculed. They hold election and predestination; regard the doctrine of the Trinity as not essential to salvation; maintain that there is no precept in Scripture, which commands the worship of the Holy Ghost; and affirm that Jesus Christ is not equal to God the Father.

ARMISTICE, in military affairs, a temporary truce, or cessation of arms for a very short space of time.

The word is Latin, *armistitium*, and compounded of *arma*, arms, and *sto*, to stand, or stop.

ARMOSIN, a kind of silk stuff, manufactured in the East-Indies, at Lyons in France, and at Lucca in Italy.

ARMONICAL, or AMMONIAC. See SAL AMMONIACUM.

ARMORIAL, something relating to arms, or coats of arms.

ARMORY, a magazine of arms, or a place where military habiliments are deposited, that they may be ready for use.

ARMORY also implies a branch of the science of heraldry, consisting in the knowledge of coats of arms, with regard to the blazonry and various indentments.

ARMOUR,

ARQ

ARMOUR, all such habiliments as serve to defend the body from wounds, especially those given by darts, swords, lances, &c.

ARMOURER, a person who makes or deals in arms or armour.

ARMS, *Arma*, in a general sense, all kinds of weapons, whether offensive or defensive.

ARMS, in a legal sense, extend to any thing a person wears for his own defence, or takes in his hand, and uses in anger, to strike or throw at another.

ARMS, or **ARMORIES**, in heraldry, signify marks of honour borne upon shields, banners, and coats, in order to distinguish kingdoms, states, families, and persons.

Charged ARMS are such as retain their ancient integrity, with the addition of some new honourable bearing.

Canting or Vocal ARMS, those in which there are some figures alluding to the name of the family.

Pure or Intire ARMS, such as retain their primitive purity, without any alterations or abatements.

False ARMS, such as are not conformable to the rules of heraldry.

ARMS, in falconry, imply the legs of a hawk from the thigh to the foot.

ARMY, a large number of soldiers, consisting of horse and foot, completely armed, and provided with artillery, ammunition, &c. under the command of one general, with proper officers under him.

An army is composed of squadrons and battalions, and is usually divided into three corps, and formed into three lines. The first is called the vanguard, the second the main body, and the third the rear-guard.

ARNOLDISTS, in ecclesiastical history, a sect of separatists, so called from their leader, Arnold of Brescia, a great declaimer against the wealth and vices of the clergy. He is also charged with preaching against baptism and the eucharist.

AROMATIC, an epithet applied to such plants and other bodies as yield a fine fragrant smell, and have a warm spicy taste.

AROPH, a term frequently used by Paracelsus for lithontriptic medicines.

AROURA, a Grecian long measure, containing fifty feet. It was also frequently used for a square measure of half the plethron. The Egyptian aoura was the square of a hundred cubits.

ARPENT, a term sometimes used to denote an acre.

ARQUEBUSS. See **HARQUEBUSS**.

ARQUEBUSS, a *erc*, in military affairs, a firearm still found in most old castles, pretty much resembling the barrel of a musket, and sustained by an iron swivel which is fastened to its barrel, and

ARR

supported by a foot called a *chevalet*, or three-legged horse. This piece was formerly much used to mount on battlements, and at loop-holes; but is now almost entirely neglected, being used nowhere but in old forts and castles where it is found. The barrel of an arquebuse a *croc*, is larger than that of a musket, but much less than a cannon's; they are charged in the same manner as a cannon, and like them, fired with a match; the range of this piece is greater than that of a musket.

ARRACHEE, in heraldry, a term applied to the representation of plants torn up by the roots.

ARRAC. See **ARAC**.

ARRAY, in law, implies the ranking or setting forth a jury or inquest of men impanelled on some cause.

Battle ARRAY, the order or disposition of an army drawn up with a view to engage the enemy.

ARREARS, the remainder of a sum due, or money remaining in the hands of an accountant. It likewise signifies the money due for rent, wages, &c. or what remains unpaid of pensions, taxes, &c.

ARRENATION, in the forest laws; implies the licensing the owner of lands in a forest, to inclose them with a low hedge and a small ditch, in consideration of a yearly rent.

ARREST, the apprehending and seizing a person, in order to oblige him to be obedient to the law; which in all cases, except treason, felony, or breach of the peace, must be done by virtue of a precept out of some court. See **WRIT**.

ARREST of Judgment, the assigning just reason why judgment should not pass, as want of notice of the trial, a material defect in the pleading, when the record differs from the deed impleaded, when persons are mis-named, where more is given by the verdict than is laid in the declaration, &c. This may be done either in criminal or civil cases.

ARRESTS, in farriery, many tumours between the ham and the pastern of a horse's hind legs. See **RAT-TAILS**.

ARRHEPHORIA, a festival among the Athenians, in honour of Minerva. The maisters who assisted at it were boys and girls, between seven and twelve years of age.

The word is Greek, and compounded of *αρρητος*, mystery, and *ορος*, to carry.

This feast was also called *Hersiphori*, from *Herse*, the daughter of *Cecrops*, on whose account it was instituted.

ARRIERE, the hinder or posterior part of any thing. See **REAR**.

ARRONDEE, in heraldry, implies a cross, the arms of which are composed of sections of a circle.

ARROW, a missive weapon, sharp-pointed and barbed, designed to be shot from a bow. See **Bow**.

ARROW,

ARROW, among surveyors, implies a small stick generally shod with iron, to stick into the ground, at the end of the chain.

ARSCHIN, in commerce, a long measure used in China to measure stuffs. Four arschins make three English yards.

ARSENIC, a poisonous mineral substance, frequently found mixed with other matters.

The chemists have formed various conjectures about the nature of this singular concrete; but have not been able to determine what it really is, or to what class of bodies it belongs. They have called it sulphureous, unctuous, mercurial, a mineral juice, &c. without foundation. Boerhaave, in his *Elementa Chemiæ*, ranks it under the head of sulphurs, and says it approaches nearer to the nature of sulphur than of any other known mixt body: it wants, however, the peculiar qualities by which sulphur is distinguished. Stahl, with greater probability supposes it to be of a saline nature. In some of its states, it apparently possesses properties attributed to salts alone; but in other states, it is as obviously metallic.

White arsenic, or arsenic strictly so called, is a moderately heavy, compact, hard, brittle concrete; of a crystalline or vitreous appearance, gradually changing, from exposure to the air, to a milky hue like that of porcelain, and at length to the opaque whiteness of white enamel. The larger masses preserve their transparency longer than the small; in a dry longer than in a moist air.

In the fire, it neither burns, nor perfectly melts; but totally and readily exhales in thick fumes, of a strong fetid smell resembling that of garlic. The fumes, caught in proper vessels, condense, either into crystalline masses again, or into a white powder, according as the receiver is less or more removed from the heat.

Mixed with inflammable matters, and exposed to the fire in a retort or other like vessel, it assumes a metallic appearance. In this state, it greatly resembles regulus of antimony; being, like that femimetal, of a bright sparkling whitish colour, a plated or leafy texture, and very brittle: but its whiteness soon changes in the air to a dark blackish hue. It still continues volatile, as in its unmetallic form: it burns and calcines in the fire, and sublimes into white arsenic, as at first.

Arsenic reduced into fine powder, and boiled in fifteen times its weight of water, totally dissolves. If the solution be evaporated a little, the arsenic shoots; on cooling, into crystals, which frequently have a yellowish tinge. The entire crystals are not taken up again by boiling water; but when finely pulverized, they dissolve as at first. The solution has a nauseous taste, but not a saline sharpness.

Arsenic dissolves both in acid and in alkaline liquors, but makes no effervescence with either:

in fixed alkaline lixivia it dissolves very plentifully; in acids, more sparingly. Arsenic in its femimetallic form, called regulus, is easier of solution than the white arsenic or calx.

Arsenic is employed for sundry mechanic uses; by the dyers, as an ingredient in the compositions of scarlet and other fine reds; by the girdlers and pinmakers, for whitening their bras or copper; by the goldsmiths, for enamelling; by the glass-makers, for promoting the fusion of the frits, and the clearness and transparency of the glass; by the porcelain-makers, in white glazings; by the preparers of compound metals, for communicating a silver whiteness to copper; by the assayers, it is used, in the form of glass, for promoting the scorification of refractory ores, which participate of tin and antimony, and which will not work off, but run into lumps in the cupel. A certain artist at Berlin prepares a beautiful metal, like the finest steel, by melting cast iron with arsenic and glass, and adding a little tin during the fusion: the beauty of the metal depends in a great measure upon the proportions. In Vienna, a metal is made for ornamental uses, resembling the finest silver, from iron, tin, and arsenic; perhaps with the addition of a little copper. Arsenic is used also in folders, or for uniting iron with tin, in some places in the making of tinned iron plates.

Arsenic is a most violent poison to all animals; unless the wolf should be an exception, who is said, probably without sufficient foundation, to be only purged by it. The utmost caution is therefore necessary, in all operations upon arsenic, to avoid its fumes: it is on account of the danger attending such operations that this mineral has hitherto been so little examined by the chemists. The destroying of rats, or other domestic animals, by means of arsenic, is full of danger; the operation of the poison being such, that great part of it is discharged, and the animal induced to drink: hence foods, liquors, and the provender of cattle, have too often received a poisonous taint. If we cannot catch those animals, we may nevertheless be cleared from them by much safer means than the use of arsenic: fresh night-shade is their enemy. If the juice of the leaves or berries of that plant, or the distilled water of the fresh herb, be made into pellets with meal, the rats, without tasting the pellets, will forsake the places where they are laid.

ARSIS and **THESIS**, in music, is a term applied to compositions, in which one part rises and the other falls.

ARSMART, in botany, the name of several species of periscaria. See **PERSICARIA**.

ART, *Artis*, a system of rules serving to facilitate the performance of certain actions; in which sense it stands opposed to science, or a system of speculative principles.

Arts are commonly divided into liberal and mechanical; the former comprehending poetry, painting, sculpture, architecture, &c; and the latter, the whole body of mechanical trades, as carpentry, masonry, turnery, &c.

ART and PART, in the law of Scotland, is applied to an accomplice.

ARTEDIA, in botany, a genus of pentandrious plants, with hairy leaves much resembling those of the carrot; the flower stalks are terminated with large umbels of white flowers, composed of five unequal petals; these are succeeded by roundish compressed fruit, each having two seeds, which are oblong, and their borders scaly.

ARTEMISIA, mugwort, in botany, a genus of plants producing a flower, composed of hermaphrodite and female floscules, the disk or middle composing the hermaphrodite, which are funnel-shaped and cut in five parts at the brim, containing five capillary filaments; on the border are ranged the female floscules, which have a germin at their bottoms, supporting a single style; they both afterwards produce each a single naked seed. The common mugwort is perennial, and grows wild in fields and waste grounds, and flowers in June; the stalks of it are firm, and of a purplish colour; the leaves are deeply divided, of a dark green colour above, but hoary underneath, and much like common wormwood; and the flowers stand erect in spikes on the tops of the branches: to this genus Linnaeus has added the southernwood and wormwood.

The common mugwort is said to be opening and discussive, and has been chiefly recommended for promoting the uterine evacuations, and abating hysterical spasms, for which purpose infusions of it have been drank as tea: amongst midwives and nurses it is held in the greatest esteem, as it is much used in complaints peculiar to the female sex, both in inward and outward applications.

The moxa, so famous in the eastern countries for curing the gout, by burning the part affected, is the down which is on the under part of the leaves of a species of the artemisia, and is by some supposed to be the yzecuipathi of Hernandez.

ARTERIAL, in anatomy, any thing belonging to, or that performs the office of, an artery.

ARTERIAL Vein, in anatomy, a name given to the pulmonary artery.

ARTERIOTOMY, the opening an artery in order to procure an evacuation of blood.

The word is Greek, *αρτηριωσις*, and compounded of *αρτηρια*, an artery, and *τομή*, to cut.

ARTERY, in anatomy, a conical tube or canal, which conveys the blood from the heart to all parts of the body.

An artery is composed of three membranes or coats; the outermost of which appears to be a

web of fine blood vessels and nerves, for conveying nourishment to the interior membranes. The next is composed of circular or spiral fibres, of which there are more or fewer, according to the magnitude of the artery. These fibres, being very elastic, contract themselves with some force, when the power ceases by which they have been extended. The third and innermost membrane is of a dense contexture, yet fine and transparent. It serves to keep the blood within its channels, which otherwise would, upon the dilatation of the artery, separate the spiral fibres from one another. The pulse of the arteries consists of two reciprocal motions, like the pulse of the heart, being a systole and a diastole, keeping opposite times; the systole of the one answering to the diastole of the other.

The arteries of the human body are, strictly speaking, only two, namely, the aorta, and the pulmonary artery; all the other arteries, though distinguished by proper names, being only branches of these two.

The ascending aorta, which arises immediately from the left ventricle of the heart, presently after gives two arteries, called coronary ones, to the heart itself. A little above this it is divided into three ascending branches, from which are formed the two carotids, and the two subclavians; and from these last proceed the muscularis colli, the external scapular artery, the superior intercostals, the mediastinal artery, the superior diaphragmatic artery, the mammary artery, and the axillary arteries: all which are subdivided into lesser branches.

From the descending trunk of the aorta, proceed in the following order, the bronchial artery, the inferior intercostals, the arteries of the oesophagus, the interior diaphragmatics, the coeliac, superior mesenteric, the renal or emulgent arteries, the sacra, and two iliacs. These are the main branches sent out from the descending aorta, each of which is again subdivided into many lesser branches.

But Plate XV. which is taken from Drake's Anatomy, will give a much better idea of the arteries of the human body, than is possible to be conveyed by words.

1. The aorta cut from its origin at the left ventricle of the heart. *Fig. 3.* of the same plate, represents part of the trunk of the aorta turned inside out; *a, a,* the internal, or nervous coat; *b, b,* the muscular coat; *c,* the external, or vascular coat.

A. The three semi-lunar valves of the aorta, as they appear when they hinder the blood from coming back into the left ventricle of the heart, in its diastole.

2, 2. The trunk of the coronary arteries arising from the aorta.

3. Ligamentum arteriosum.

4, 4. The subclavian arteries.

5, 5. The

5, 5. The two carotid arteries.
6, 6. The two vertebral arteries, which arise from the subclavicular, and pass through all the transverse processes of the vertebrae of the neck.

7, 7. The arteries which convey blood to the lower part of the face, tongue, adjacent muscles and glands.

8, 8. The trunks of the temporal arteries springing from the carotids, and giving branches to the parotid glands.

9, 9. Branches of the temporal arteries, conveying blood to the neighbouring muscles, the hairy scalp, and forehead.

10, 10. The trunks which send blood to the foramina narium, particularly to the glands of its mucous membrane.

11, 11. The occipital arteries, whose trunks pass close by the mammiform process.

12, 12. Muscles which carry blood to the fauces, gurgareon, and muscles of those parts.

B, B. Small portions of the basis of the skull, perforated by the artery of the dura mater, part of which is represented as hanging to the arteries.

13, 13. The contortions of the carotid arteries, before they pass the basis of the skull to the brain.

14, 14. Those parts of the carotid arteries, where they pass by each side of the fella turcica, where several small branches arise from them, and help to compose the rete mirabile.

C. The glandula pituitaria, taken out of the fella turcica, lying between the two contorted trunks of the carotid arteries, marked 14, 14.

D, D. The arteria ophthalmicae, which spring from the carotids before they enter the pia mater.

15. The contortions of the vertebral arteries, as they pass the transverse processes of the first vertebrae of the neck, towards the os occipitis.

16. The two trunks of the vertebral arteries that lie on the medulla oblongata.

17. The communicant branches between the carotid and cervical artery.

18, 18. The ramifications of the arteries within the skull, the larger trunks of which lie between the lobes of the brain, and its sulci.

E, E. The arteries of the cerebellum.

19, 19. The arteries of the larynx, thyroid glands, and adjacent muscles and parts arising from the subclavian arteries.

20, 20. Others arising near the former, which convey blood to the muscles of the neck and scapula.

21, 21. The mammae, which arise from the subclavian arteries, and descend on the cartilages of the true ribs internally, on each side the os pectoris or sternum. Some branches of these pass through the pectoral as well as intercostal muscles, and give

blood to the breasts, where they meet some branches of the intercostal arteries.

22, 22. The arteries of the muscles of the os humeri, and some of those of the scapula.

23, 23. Those parts of the large trunks of the arteries of the arm, which are liable to be wounded in opening the vena basilica, or innermost of the three veins in the bending of the cubit.

25, 25. A communicant branch of an artery arising from the trunk of the artery of the arm, above its flexure at the cubit, which is inoculated with the arteries below the cubit.

26, 26. The external artery of the cubit, which makes the pulse near the carpus.

27, 27. Arteries of the hands and fingers.

28, 28. The descending trunk of the arteria magna.

29. The bronchial artery, springing from one of the intercostal arteries: it sometimes arises immediately from the descending trunk of the aorta; and at other times from the superior intercostal artery which springs from the subclavian.

30. A small artery, springing from the fore parts of the aorta descendens, and passing to the gula.

31, 31. The intercostal arteries on each side the arteria magna descendens.

32. The trunk of the arteria cœliaca, whence spring,

33, 33. The hepatic arteries, and

34. The arteria cystica, or the gall-bladder.

35. Arteria coronaria ventriculi inferior.

36. The pylorica.

37. The epiploica dextra, sinistra, and media, springing from the coronaria.

38. The ramifications of the coronary artery, which embrace the bottom of the stomach.

39. Coronaria ventriculi superior.

40, 40. The phrenic arteries, or the two arteries of the diaphragm; that on the left side arising from the trunk of the arteria magna; the right springing from the cœliaca.

41. The trunk of the splenic artery, arising from the cœliaca, contorted.

42. Two small arteries going to the upper part of the duodenum and pancreas; the rest of the arteries of the pancreas spring from the splenic artery in its passage to the spleen.

43. The trunk of the arteria mesenterica superior turned towards the right side.

44. The branches of the superior mesenteric artery freed from the small guts. Here the various anastomoses the branches of this artery make in the mesentery, before they arrive at the intestines, may be observed.

45. The inferior mesenteric artery arising from the arteria magna.

46. Remarkable anastomoses of the mesenteric artery, with the superior.

- 47, 47. The branches of the inferior mesenteric artery, as they pass to the intestinum colon.
48. Those of the rectum.
49. The emulgent arteries of the kidneys.
50. The vertebral arteries of the loins.
- 51, 51. The spermatic arteries, which descend to the testes, and are so small as to escape being filled with wax.
52. Arteria sacra.
53. Arteriae iliaci.
- 54, 54. Rami iliaci externi.
- 55, 55. Iliaci interni.
- 56, 56. The two umbilical arteries cut off; that on the right side is drawn as in the foetus, and the left expressed as in an adult.
- 57, 57. The epigastric arteries, which ascend under the right muscles of the abdomen, and are inoculated with the mammariae.
- 58, 58. Branches of the external iliac arteries, passing between the two oblique muscles of the abdomen.
- 59, 59. Branches of the internal iliac arteries, which convey the blood to the extensores and obturatores muscles of the thighs.
- 60, 60. The trunks of the arteries which pass to the penis.
- 61, 61. The arteries of the bladder.
- 62, 62. The internal arteries of the pudendum, which, with those here expressed with the penis, make the hypogastric arteries in women.
63. The penis extended with wax, and dried.
64. The glans penis.
65. The upper part of the dorsum penis, cut from the body of the penis, and raised, to shew the corpora cavernosa penis.
66. Corpora cavernosa penis, freed from the ossa pubis, and tied after inflation.
67. The two arteries of the penis, as they appear injected with wax.
68. The capsula and septum of the corpora cavernosa penis.
69. The crural arteries.
- 70, 70. The arteries which pass to the muscles of the thighs and tibiae.
71. That part of the crural artery that passes the ham.
72. The three large trunks of the arteries of the legs.
73. The arteries of the foot, with their communicating branch, from their superior to their inferior trunk, as well as their communications at the extremity of each toe, like those of the fingers.

Rough ARTERY, or aspera arteria. See ASPERA ARTERIA.

ARTHANITA, fowbread, in botany, a low plant, without any other stalk than the slender pedicles of the leaves and flowers: the leaves are pretty large, round, of a green colour, above

with white specks, and purplish underneath: the flowers purplish, monoetalous, deeply divided into five segments, followed by round seed vessels: the roots large, somewhat globular, with several fibres, blackish on the outside, and white within. It is perennial, a native of the southern parts of Europe, and cultivated in some of our gardens.

ARTHRITIS, in medicine, a disease well known by the appellation of the gout. See the article *GOUT*.

The word is Greek, and derived from *αρθρον*, a joint; because the chief seat of that distemper is in the joints.

ARTHRODIA, in anatomy, a species of articulation, wherein the flat head of one bone is received into a shallow socket in the other. The humerus and scapula are joined by this species of articulation.

The word is Greek, and compounded of *αρθρον*, a joint, and *δεχομαι*, to receive.

ARTHRODIUM, in natural history, a genus of imperfect crystals, always found in complex masses, and forming long single pyramids, with very short and slender columns. See *CRYSTAL*.

ARTICHOKE, cynara, in botany, a well known plant, of which there are two sorts cultivated in gardens; one known by the name of the globe artichoke, and the other called the French artichoke. The globe artichoke produces large round heads, with broad brown scales turning inward: the eatable part at the bottom of the scales is very thick, and better flavoured than the other sort, which produces taller stalks, with less heads, and conically shaped; the scales are narrower, and have less flesh at their bottoms; on which account the French sort is pretty much excluded from the English gardens, the other being considerably preferable.

The artichoke delights in a deep rich and moist soil, well prepared with rotten dung, and mixed to the depth of three feet at least; for the deeper the mould is, the less watering they will require in summer, and produce larger and better flavoured heads. The manner of propagating this plant, is from the slips or suckers (though they may be raised from seed) which arise from the old roots in February or March, or as soon as the hard frosts are over, which if planted in a proper soil will produce good fruit in the autumn following. These suckers should be carefully taken off with roots to them, particularly where a fresh plantation is intended; and as they are pretty deep in the ground, the earth should be removed from around the mother plant, to take them off the more easily, leaving two or three of the straightest, clearest, and most promising plants, which are produced from the under part of the stock, for a crop, observing in slipping off the other suckers, to be careful not to injure those which are designed to remain,

main. When this operation is done, the earth should be drawn to the plants which are left, and well closed to them, cutting off the extremity of the leaves which hang down; after which, the ground between them should be dug, and a crop of spinage may be sown, which will be taken off before the artichokes cover the ground. Toward the latter end of April, or beginning of May, when the plants begin to shew their fruit, all the young shoots produced from the root since the last dressing should be displaced, so as to leave only the principal plants which are intended for fruiting, which will by that means bear the better, and likewise to take off all the suckers that are produced from the sides of the stalk, leaving only the principal head, which will cause the fruit to be considerably larger. When the artichokes are fit to be used, they should be cut, and the stalks broke off close to the surface of the ground, in order that the stocks may make fresh shoots before the end of October, which is the season for earthing them up, although it may be deferred till any time in December, provided the season proves mild.

The method of earthing artichokes, (or landing them, as by some called) consists in cutting off all the young shoots quite close to the ground, then digging a trench between each row, and covering the roots with the earth thrown up in form of a ridge, over the line of the artichokes: this will secure them from the frosts that are common, and is by far much better than covering them with long dung, which is a bad practice, because the dung laying near the roots is very apt to rot them, besides harbouring of vermin, which may destroy the roots; though it would not be amiss in very severe frosts, to put straw, peas-haulm, &c. on the ridges, which will keep some part of the extremity of the weather from them, without damaging the roots; but this covering need not be used till there is no avoiding it, and so soon as the weather becomes mild, it should be taken off, for it will be a disservice to the plants, if it lies too long on them. After the plants are earthed up with the afore-mentioned precautions, they will not want any farther care till February or March, when they will have grown through the ridge of earth, and must be managed as before-directed.

Though the stocks of artichokes will last several years in a good rich soil, yet as they are great impoverishers of the ground, their fruit will dwindle so as to render it necessary to have a fresh plantation every fourth or fifth year, or rather every year, on account of having their fruit in autumn; for this purpose, the ground being prepared and provision made of a sufficient number of suckers, make choice of those which are clear, sound, and not woody, having some fibres to their bottom; with a knife cut off the knotted part which joined to the stalk. If it cuts crisp and tender, it is a sign

of the sucker's being good; but if tough and stringy, it is to be rejected. Having properly singled out those which are fitting for the purpose, cut the large outside leaves off pretty low, in such a manner that the middle leaves may rise above them; the plant being thus prepared, the best method of planting is in rows as strait as possible, which must be done by ranging a line across the ground, setting them at about two feet asunder in each row; and if more rows are wanted than one, these should be at the distance of five feet, and the plants set in quincunx order: the depth they should be planted to be about four inches, and the earth well closed about the roots; and if the season proves dry, they should be often watered till they have taken good root: if the season proves favourable for them, and particularly on a moist rich soil, these plants will produce the largest and best artichokes some time in August and September, after the old stocks have ceased bearing; so that the season is considerably lengthened for producing this fruit, by making a new plantation every year.

The kitchen-gardeners near London, who endeavour to make the most of every inch of their high-rated land, generally plant their rows of artichokes nine or ten feet asunder, and besides sowing between them radishes or spinage, they plant two rows of cauliflowers, at the distance of two feet and a half asunder in rows, and four feet from row to row, so that full five feet are allowed for the artichokes. In May when the crop of radishes or spinage is off, they follow along the middle of the space between the two rows of cauliflowers, a line of cucumbers for pickling, at the distance of three feet; and between the cauliflowers and artichokes, they plant for winter-use a row of cabbages, or favours, which have room enough to grow after the cauliflowers and artichokes are taken off: thus the ground is fully cropped during the whole season. A moist rich soil always yield the largest and best artichokes, but if it be very moist, the roots will not live through the winter: such ground should therefore be allotted for fresh plantations, made every spring, to supply the table in autumn, after the old stocks have done bearing; but for early fruit, the plants should be in a drier situation; they should be also in an open place, that is free from the drip of trees, for they would draw the plants up weak, and thereby render the fruit small and trifling. If the artichoke stocks shoot forth but weakly in the spring, as they will do if they have been hurt by frost, or too much wet, it is best to uncover them with a spade, loosening and breaking the mould around them, or rather to dig the whole ground, if it be not planted with any thing else, and then to earth or raise a small hill about each stock, which will greatly help them: in about three weeks or a month after, the slips will be fit to take off.

The bottoms of artichokes are good for many culinary uses. The way to preserve them all the winter is to separate them from the leaves or scales, parboil them, and hang them up in a dry place, strung on packthread, with a clean piece of paper between every bottom, to prevent their touching one another; they are likewise said to be very good pickled. The artichoke suckers, which grow on the sides of the stalk, are also used in several intentions in cookery.

Artichokes are accounted a diuretic, and good against the jaundice; but they are more esteemed as a food than a medicine. For the general characters of the artichoke, see the article CYNARA.

ARTICHOKE of *Jerusalem*. See HELIANTHUS.

ARTICLE, a small part of a book, writing, account, treaty, or the like.

ARTICLE, in anatomy, implies the juncture of two bones designed for motion.

ARTICLE, in arithmetic, denotes any number that can be divided into ten equal parts, as 10, 20, 30, &c.

ARTICLE, in grammar, signifies a particle which is made use of in most languages to express the case, gender, and circumstance of nouns.

In those languages whose termination does not vary, or, to speak more accurately, whose nouns have no particular declension, articles are absolutely necessary to determine their cases, or shew what relation they stand in, with regard to the verb. Thus the Italians have their *il, lo, la*; the Germans their *der, das, dat*; the French their *le, la, les*, by which they mark the circumstances of their nouns.

In English we have two articles, *a*, and *the*; the former of which is an *indefinite* article, because applied to nouns in their more general signification; and the latter *definite*, or demonstrative, because it fixes the sense of the word it is put before to one individual thing. Thus, if we translate the following words, which Satan made use of to our Saviour, *Si tu es filius Dei*, "If thou art a son of God," we degrade Christ into the order of angels, who are called in Scripture the sons of God; whereas if it is rendered "If thou art *the* Son of God," it is then making him the Messiah, or the only begotten of the Father.

The Latins make use of no article; but instead of it, when they would mark any thing particularly, they employ the pronouns *is, hic, ille, iste*;—thus, *Unum erat ei, si natus non fuisset homo ille*, "It was well for *thee*, or *that* man, if he had not been born;" thus too, in Virgil, *Hæc illa Charybdis*, "This is *the* Charybdis." The Greeks have their *ὁ*, which is constantly prefixed to a word when they intend to mark it as particular, or emphatic: thus, in the first chapter of St. John, *Ἐν ἀρχῇ ἦν ὁ λόγος, καὶ ὁ λόγος ἦν πρὸς τὸν θεόν, καὶ θεὸς ἦν ὁ λόγος*, which ought to be translated thus, "In *the* beginning was *the* Word, and *the* Word

was with God (i. e. with the only one true God) and the word was a God, or as a God;" it should not be translated *God*, for then there ought to have been the article *ὁ*, to have distinguished and made it emphatic. And here I cannot help remarking how blind has been the zeal of some well-meaning people, who have fixed upon this one text in Scripture, preferably to all others, to confute the followers of Arianism, when this, perhaps of all others, is one under which they can best shelter themselves.

It is not agreed by grammarians under what class of words the article should be reckoned: some make it a distinct part of speech, others will have it to be pronoun, and others again a noun adjective. This does not seem to be a very interesting point, and so we shall beg leave to drop it, just as we found it, without determining any thing of the matter.

ARTICLE of *Death*, *articulus mortis*, the last pangs, or agony of a dying person.

ARTICLE of *Faith*, a point of religious doctrine, allowed and received by some church or religious sect, as having been revealed from heaven.

ARTICLES of the *Clergy*, certain statutes relating to ecclesiastical persons and causes, made in the reigns of Edward the Second and Third.

ARTICLES of *Religion*, the thirty-nine heads of the protestant faith, drawn up by the bishops Cranmer and Ridley, and published by regal authority in the reign of Edward the Sixth.

ARTICULARIS MORBUS, the disease of the joints, generally called the gout. See GOVT.

ARTICULATE *Sounds*, such sounds as express the letters, syllables, or words of any alphabet or language; such as are formed by the human voice.

ARTICULATED, something furnished with, or consisting of joints.

ARTICULATED *plants*, are such as are distinguished from space to space, by knots or joints along their stems.

ARTICULATION, in anatomy, implies the juncture of two bones intended for motion.

Articulation is of two kinds, diarthrosis and synarthrosis, the former being that which admits of a manifest motion, and the latter that which allows only of an obscure motion. See DIARTHROSIS and SYNARTHROSIS.

Diarthrosis is subdivided into enarthrosis, arthro-dia, and ginglymus. See each under its proper article. And synarthrosis is subdivided into symphysis, syntenosis, futura, harmonia, fissuræcosis, sycondrosis, and synneurosis. See the articles SYMPHYSIS, &c.

ARTIFICER, a person whose employment it is to manufacture any kind of commodity, as iron, brass, wood, wool, linen, &c. such as smiths, braziers, carpenters, weavers, spinners, &c.

ARTIFICIAL, something made, fashioned, or produced by art, in contradistinction to the productions of nature.

ARTIFICIAL	Day.	See the article	DAY.

	Vortex.		VORTEX.

ARTILLERY, the general name for all sorts of large fire-arms, or the engines used in war since the invention of gun-powder, as cannon, mortars, bombs, petards, musquets, carabines, &c. See **CANNON**, **MORTAR**, &c.

The first pieces of artillery were of a very clumsy inconvenient shape, being usually framed of several pieces of iron fitted together lengthwise, and then hooped with iron-rings; and as they were used for throwing stones of a prodigious weight, in imitation of the ancient machines, to which they succeeded, they were of an enormous bore. But the difficulty of conducting and managing these pieces, and the discovery, that iron bullets of much less weight, impelled by better powder, were more efficacious, soon introduced the present matter and fabric of cannon.

The term **ARTILLERY** is also applied to the ancient instruments of war, as the catapulta, battering-ram, &c.

Train of ARTILLERY, a certain number of pieces of ordnance, mounted on carriages, with all their furniture, and every thing necessary for marching; it is divided into brigades; each brigade generally consists of eight or ten pieces of cannon, with all the machinery belonging to them, and officers to conduct them. When the artillery marches with the army, the military-chest is placed at the head of the train.

There are also a number of pioneers, proportioned to the repairs the roads are supposed to require, who march after the first battalion of the royal artillery, and are under the direction of a skilful officer, in capacity of their commander.

The heaviest brigade, or that which is composed of the heaviest cannon, marches in the center; so that, if there are six light brigades, three march behind and three before this heavy brigade, which is sometimes called the *park-brigade*.

All the brigades, except the park-brigade, change places, and are alternately at the head and in the

rear, that the fatigue of each post may be equally divided.

The provincial commissaries march at the heads of their brigades, and see that the officers appointed to conduct them preserve the order of the march, and do not quit their post till the brigade arrives at the place intended, called the park.

ARTILLERY-Park, is the place appointed by the general of the army to lodge the train of artillery; the ammunition is disposed in the same order as the battalions of the royal artillery, appointed for its defence and service.

The figure of the park of artillery is that of a parallelogram, if the situation of the ground does not make another form necessary.

Some commandants place the pieces of the first line first, and next to these the waggons containing the ammunition intended for the service of these pieces; and afterwards arrange the pieces of the second line in the same manner, forming the first line with one half of the artillery, and the second with the other. These gentlemen are of opinion that the park may be divided in this order with less confusion than any other method: others think that by placing all the cannon in the first rank, and the proper ammunition behind each brigade, the park is raised; i. e. the artillery renews its march with as much ease and better effect.

The pieces of cannon and carts ought always to be two paces distant from each other, the brigades five paces, and the lines forty paces: when there are pontoons in the train, they form the last rank, and are forty paces behind the preceding.

The park-guard consists of fifty men, draughted from the battalions of the royal artillery, who are posted over-against the park, at the distance of forty or fifty paces from the front: from these also the centinels of the park are draughted, two of which are posted at each rank, sword in hand, without fire-arms.

The battalions of the royal artillery are placed at the right and left of the park, and the carriage-horses about three hundred paces distant, in a commodious place on the right or left, where they may be out of danger.

When the army is encamped in form in a field, or open place, the artillery is placed over-against the center of the first line, formed by the troops, at the distance of three or four hundred paces from the front of this line, if the ground will permit; otherwise, it is placed at the distance of two or three hundred paces behind the center of the second line.

About one hundred paces before the park, are planted three advanced pieces of cannon, charged and ready to be fired, which are called *alarm-pieces*, because they are used to call in on a sudden the troops which are foraging, when there is a necessity for so doing, and to give the alarm for the whole army

army to put itself under arms; or for any other purpose to which the general thinks proper to appoint them. A cannoner is always posted near these pieces with a match ready lighted.

ARTILLERY-Company, a band of infantry, consisting of six hundred men, making part of the militia, or city-guard of London.

ARTIST, a person skilled in some art.

ARTOTYRITES, in ecclesiastical history, a sect who, in celebrating the holy sacrament, made use of cheese as well as bread; or, perhaps, bread baked with cheese: and hence came their name, which is compounded of the Greek words *αρος*, bread, and *τυρος*, cheese.

They are a branch of the ancient Montanists, who first appeared in the second century, and infected all Galatia. They admitted women into the priesthood, and into the episcopacy; and Epiphanius tells us that it was no uncommon thing to see a body of seven girls enter their church, dressed in white, with each a torch in her hand, where, like so many Magdalens, they beat their breasts, and bewailed the wretchedness of human nature, and the miseries and iniquity of the world.

ARVAL BROTHERS, *Arvales fratres*, in antiquity, a college of twelve priests, instituted by Romulus, who presided over the ambervalia, or sacrifices, annually offered to Bacchus and Ceres.

The word is Latin, and derived from *arvum*, a field; because they offered sacrifices for the fertility of the field.

Fulgentius has given us the following account of their original: "The nurse of Romulus, called Laurentia, had a custom of offering a sacrifice annually to the gods for obtaining a plentiful crop; and in these religious exercises she was accompanied with her twelve children. But one of them happening to die, Romulus, in compliance to his nurse, assisted himself to complete the original number, and gave them the title of the twelve arval brothers, which they kept ever after."

They held their assemblies in the temple of Concord, and wore on their heads a crown composed of the ears of corn, tied together with a white ribbon. Some add, that they were entrusted with the authority of determining the limits of lands and inheritances.

ARUM, wake-robin, or cuckoo-pint, in botany, a genus of glandular plants, producing a flower with a large monophyllous oblong spathe, or sheath, inclosing a pistil, which is shorter than the spathe: it is destitute of petals, style, and filaments, but hath many four-cornered anthers, adhering to a number of germen, with double rows of hairs between them, which are affixed to the pistil; each germen afterwards turns to a roundish unilocular berry, containing several seeds of the same shape. There are a considerable number of species contained in

this genus, especially as Linnæus has classed the aritarum and dracunculus of Tournefort, and the colocasfia of Boerhaave with the arum.

The common arum, which is a low perennial plant, and grows wild under hedges, and by the sides of banks in many parts of England, sends forth in March three or four smooth leaves, which are spear-shaped and triangular; these are succeeded by a naked stalk, bearing a purplish pistil, inclosed in a long sheath, which is followed in July by a bunch of red berries. The root is regularly roundish, about an inch thick, brownish on the outside, and white within. There are two varieties of this sort; one with plain leaves, and the other hath leaves full of black spots; the roots of the last are supposed to be most efficacious, and are therefore ordered by the College of Physicians. The arum roots are most violently pungent and acrimonious; inasmuch, that the least touch of its juice on the tongue is scarce tolerable, and almost caustic, producing at the same time a considerable thirst. These uneasy sensations are somewhat alleviated by milk, butter, or oils: the other parts of the plant are likewise acrid, though rather less so than the roots. This quality makes it recommended in all viscidities, and in phlegmatic, and scorbutic cases; because it penetrates and rarefies tough concretions and infarctions of the glands and capillary vessels: it hath been prescribed in humoral asthma and obstructions of the bronchia; for, by the great force and activity of its parts, it breaks through and wears away those little stoppages in the extremities and cutaneous glands, which occasion itchings and scabs; it is therefore justly ranked amongst the most powerful antiscorbutics. Some have affirmed a dram of this root fresh powdered and taken in any proper vehicle, to be a most excellent remedy against poison, the plague, or any pestilential disorder. A cataplasm of this root fresh bruised and mixed with cow-dung, is reckoned very efficacious in arthritic pains, by applying it hot to the part affected. Such a composition cannot but do all that may be expected from the most penetrating substances. This root loses much of its acrimony, by being dried to become pulverable: if kept for some time it seems, on first chewing, to be an inspissated farinaceous substance; it still, however, retains a kind of latent pungency, so as, when chewed long in any considerable quantity, to produce a sensation, as of a slight excoriation of the tongue. These roots are generally gathered in the spring, when the leaves are in full vigour: by taking them up that time of the year they soon lose their pungency; but if they are taken in autumn, when their leaves are decayed, they will retain their quality perhaps a year, or more, at which time, when fresh, they yield on expression a milky juice, about a sixth part of its weight, which, on standing, deposited a white fecula, and became clear; the clear liquor was in-
spid

lipid, the secula was considerably pungent, but like the root in substance, loses its pungency on being dried: the fresh and the moderately dried roots were digested in water, in wine, in proof spirit, and rectified spirit, with and without heat; the liquors received no colour, and little or no taste in distillation; neither spirit nor water brought over any sensible impregnation from the arum. The watery and spirituous extracts also were nearly infusid; the root, nevertheless, loses in these operations almost the whole of its pungency. By beating the fresh roots with gummy resins, and making the mixture into pills, its virtue might be better preserved than in the form of powder; the proportions of the gums in these compositions may be very considerable, two or three grains of the arum being a sufficient dose. It likewise preserves its acrimony unabated for several months, if beaten with sugar into a conserve, its virtue seeming to be retained as long as its native aqueous humidity. Though spirituous liquors are incapable of dissolving or extracting the active matter of the arum; they seem nevertheless, when given along with the dried root, as a vehicle to promote its action. Juncker observes, that a drachm of the powder taken with a spoonful of brandy, procures a very copious sweat, even in persons little disposed to that evacuation, while the powder by itself has no such effect. Most of the other species of arum being natives of the hot countries, they therefore require a stove in this climate.

ARUM *Æthiopicum*. See CALLA.

ARUM *Scandens*. See DRACONTIUM.

ARUNDELIAN *Marbles*. See MARBLE.

ARUNDO. See REED.

ARUNDO *Saccharifera*. See SACCHARUM and SUGAR.

ARUSPICES, in antiquity, an order of priests among the Romans, that pretended to foretell future events, by inspecting the intrails of beasts killed in sacrifices.

The word is Latin, and derived from *aspicio*, to view.

The aruspices were consulted on occasion of all portents and prodigies. Women were admitted into this order.

ARYTÆNOIDES, in anatomy, the name of the third and fourth cartilages of the larynx. See LARYNX.

The word is formed from the Greek, *αρυταν*, an ewer, and *ειδος*, resemblance, they being thought to resemble an ewer in shape.

ARYTÆNOIDEUS, in anatomy, one of the muscles that closes the larynx, having its head inserted in one arytenoid cartilage, and its tail in the other; serving at once to draw them together, and shut the rima, or glottis.

ARYTHMUS, among physicians, implies the want of a just modulation in the pulse; and is op-

posed to eurythmus, or a pulse modulated according to nature.

The word is Greek, *αρυθμος*, and compounded, of *α*, priv. and *ρυθμος*, measure.

AS in antiquity, a particular weight, among the Romans, consisting of twelve ounces, and was the same with what they called libra, or a pound.

As was also the name of a Roman coin, which was of different weights and different matter in different ages of the commonwealth.

Eusebius tells us, that, under Numa Pompilius, the Roman money was either of wood, leather, or shells. In the time of Tullus Hostilius it was of brass, and called *as*, *libra*, *libella*, or *pondo*; because actually weighing a pound, or twelve ounces.

Four hundred and twenty years after, the first Punic war having exhausted the treasury, they reduced the *as* to two ounces. In the second Punic war, Hannibal pressing very hard upon them, they reduced the *as* to half its weight, viz. to one ounce. And lastly, by the Papirian law, they took away half an ounce more, and consequently reduced the *as* to the diminutive weight of half an ounce; and it is generally thought that it continued the same during the commonwealth, and even till the reign of Vespasian: The *as* therefore was of four different weights in the commonwealth. Its original stamp was that of a sheep, ox, or sow. But from the time of the emperors, it had on one side a Janus with two faces, and on the reverse, the rostrum, or prow of a ship.

As was also used to denote any integer or whole; and hence the English word *ace*.

ASA, or ASSA, in the materia medica, an epithet applied to two very different substances, called *asa-dulcis*, and *asa-fetida*.

ASA-DULCIS is the same with benzoin. See the article BENZOIN.

ASA-FETIDA is a kind of gum, of a very offensive smell, produced by a plant common in some parts of Persia.

The plant which produces it is one of the pentandria dignia of Linnæus, and one of the herbæ umbelliferae femine foliaceæ, seu ala foliaceæ cinctæ of Ray. We had a multitude of various and false accounts of it for a long time; Garcias telling us it had leaves like the hazel; and Bontius making two plants of it, one like a willow, and the other with a root like a turnip; some have given it leaves like the fig-tree, some like those of rice, and others have made it a shrub of the phylleræ kind. Kämpfer is the author to whom we owe the true account of it. This is given in his *Amœnitates Exoticæ*, where he describes it fully and accurately, under the name of umbellifera levisticæ affinis foliis instar præoniæ ramosis, caule pleno maximo, femine foliaceo nudo solitario brancæ ursine sive pastinacæ simili radice asam fetidam fundente. The Persians call both the plant and the juice hingeseh; and

and the Indians, hiing; but the more accurate in both countries call the plant hingesch, and the juice or gum, hiing.

The root of this plant is perennial, and very large. It is covered with a thick black rind, which easily comes off from the rest, when fresh. Within it is perfectly white, and full of white, milky, and stinking juice, which, when collected and dried, is what the Persians call hiing, and the Europeans *asa-fetida*. The top of this root is furnished with a large tuft of hairy or filamentous matter, like that on the crown of the meum or spiguel. The leaves are very large, and like those of the piony.

The stalk is as thick as a man's arm, and grows to eight or nine feet high. It gradually becomes taper toward the top, whence it is divided into a small number of branches. The leaves stand alternately on these stalks, and that at no great distances from one another. The flowers are small, and disposed in umbels. The seeds are flat-tish and striated, and of an oval figure; they have somewhat of the *asa-fetida* smell, but much less than might be expected. It grows in Persia, but there only in two places, at least in those only in any great plenty. These are the mountains about Heraat, and the province of Laar. In these places it abounds with juice, and yields the gum in great plenty; when found elsewhere, it yields very little. The leaves in these places are of a horrible offensive smell, and no animal will touch them: but the people of the town of Diguum affirm, that, in the country beyond them, the plant loses much of its bad smell, and that the goats feed very greedily on the leaves, and grow fat upon the diet. Some have pretended to distinguish two species of this plant, the one yielding a smaller quantity of juice, and that of a less fetid smell; the other yielding more of it, and that more stinking: but Kempfer, who was upon the spot, declares the plants to be the same, and all the difference to be in the soil that produces them. If what the Persians of Diguum say be true, however, it very well accounts for the difference of the Cyrenaic and Persian kinds of sulphur; for the plant in the first of these places, might be as mild as beyond Diguum, or even more so.

It is very singular in this plant, that it seldom flowers, sometimes not till its twentieth, thirtieth, or even fortieth year. During all this time the root is increasing in size, and, consequently, it sometimes grows to an enormous bulk: roots of it have been seen of the thickness of a man's thigh, and of a yard and a half in length: those of the thickness of one's arm are frequent. When it sends forth a stalk, and has ripened its seed, it perishes. The ancients made a distinction in their sulphur, as it was produced from the stalk, or from the root of the plant; but, at this time, all that we have is obtained from the root. They never make incisions in roots of less than four or five

years standing; and they always find, that, the older and larger the root, the more plentifully the juice flows.

The gum or juice, as it flows from the root, is white, and perfectly resembles cream, and has no visciduity: on the contact of the air it dries and hardens, and becomes viscous and coloured. The most strongly scented *asa-fetida* is always esteemed the best; and Kæmpfer observes, that it is much stronger, when fresh, than when kept and imported into Europe; that a drachm of it has more scent than an hundred weight of what our druggists keep.

The leaves of the plant appear in autumn, and continue green the whole winter; in spring they wither. About the end of April, when their leaves are in their decaying state, the Persians ascend the mountains in search of the plants. They clear away the earth about the root for six or seven inches deep; they then twist off the leaves, and the fibrous substance at the top of the root. They next earth up the root again to its top, which is now perfectly bare; and this they cover with a bundle of weeds, to keep off the heat of the sun, which would otherwise destroy it. They lay a stone over all this to keep it firm, that the wind may not blow it off; and in this condition they leave the root for a month or six weeks. At the end of this time, they take off the covering, clear away the earth a little from the crown of the root, and, with a sharp knife, cut it transversely off, taking off about an inch, or a little more, of the top. They then cover this wounded root with the weeds again, making them stand hollow from the wounded part, and thus leave them for two days; at the end of which time they return, and find the top of the root, where they had cut it off, covered with exsuded juice, or *asa-fetida*: this they collect, and put up in proper vessels; and, clearing away the earth a little lower, they cut off another slice from the top of the root, but this not thicker than a crown-piece, and cover it up again for another gathering. As they take a large compass of ground for their search, they are kept in constant employment; the roots of the first day's cutting being ready for their taking the gum from, by that time they have cut the more distant ones, which they are regularly to return to afterwards. After they have gone through this second operation with all the roots, and collected the second quantity of gum from them, they cover them up for eight or ten days; and, after having spread their gum in the sun to harden it, they carry it home. Four or five men generally go out in a company, on these expeditions; and it is a common thing for them to bring home 50 lb. weight of it from this first gathering; this, however, is esteemed but an inferior kind of *asa-fetida*; after the roots have remained covered for eight or ten days, they visit them again, take off the covering of the weeds, and collect the gum. They then cut off another slice of the root, and af-

ter that another, and then a third; this is done at the distance of two days between each operation, and the earth is every time cleared away to a proper depth, and the whole process managed as before.

After the third collection in this second expedition, they cover up the roots again, and return home with their stores, leaving them covered for three days. After this, they return to their work, and cut them again three several times at the same distances of time; and, after the third collection of this last expedition, they leave them to perish; for they never recover this terrible operation. *Kemp. Amoen. Exot.*

Afa-fetida is composed of a gummy and resinous substance, the first in the largest quantity. Its smell and taste reside in the resin; which is readily dissolved and extracted by pure spirit, and the greater part with the gummy matter by water. It is by much the strongest of the deobstruent warm fetid gums; and is given not only against hysterical complaints, flatulent cholics, and obstructions of the breast, but in most nervous disorders, in which it frequently acts as an antispasmodic, and an anodyne: in some cases musk, and in others opium, are usefully joined with it. Hoffman recommends it as one of the most powerful anthelmintics hitherto known. It is most commodiously taken in the form of pills, from a few grains to a scruple, or half a drachm. It loses both its smell and strength with age; a circumstance necessary to be attended to in proportioning the doses necessary to be given in order to procure the intended effect.

ASAPPES, or AZAPES, an order of soldiers in the Turkish army, whom they always expose to the first shock of the enemy.

The word is derived from *saph*, a word in the Turkish language signifying rank, file, or order.

ASARUM, *asarabacca*, in botany, a low plant without stalks: the leaves are stiff, roundish, with two little ears at the bottom, somewhat resembling a kidney, of a dark shining green colour, somewhat hairy, set on pedicles three or four inches long: the flowers, which rise among the leaves on shorter pedicles, consist of purplish stamina, standing in a darker-coloured cup, and are each followed by a capsule, containing six seeds. It is perennial and ever-green, a native of the southern parts of Europe and the warmer climates, and raised here in gardens. The dried roots have been generally brought from the Levant; those of our own growth being supposed of weaker virtue.

The roots and leaves of *asarum* have a moderately strong, not very unpleasant smell, something resembling that of valerian or nard; and a nauseous bitterish acrid taste. The roots given in substance, in doses of a scruple or more, prove strongly emetic and cathartic. The leaves have the same effect, but their dose or degree of strength

has not been precisely determined; some say they are of more activity than the roots.

Its principal use among us is as an errhine. The root is one of the strongest of the vegetable substances commonly employed in this intention: a grain or two snuffed up the nose, procure a large evacuation of mucus, both from the mouth and nostrils, without provoking sneezing, like the white hellebore root, or discovering any remarkable irritation. Geoffroy relates, that after snuffing up a dose of this errhine, he has observed the salutary discharge to continue for three days successively, and that he has known a paralysis of the mouth and tongue cured by one dose. He recommends this medicine in stubborn disorders of the head, proceeding from viscid matters, in palsies, and in soporific distempers. During its operation the patient must carefully avoid the cold, which is apt to produce pustules, inflammations, and swellings of the face, and sometimes more alarming symptoms. This herb is the principal ingredient in the cephalic, or sternutatory powders of the shops: some take equal parts of dried *asarum*, and *marjoram* leaves; others equal parts of the dried leaves of *asarum*, *marjoram*, and *marum syriacum*, and dried lavender flowers. The empyrical herb snuffs have likewise the leaves of *asarum* for their basis; but often mixed with ingredients of a more dangerous nature.

ASBESTINE, some incombustible body, or that partakes of the nature and properties of asbestos.

ASBESTOS, salamanders wool, in natural history, the same with *amianthus*. See the article *AMIANTHUS*.

The word is Greek, and compounded of *as*, priv. and *σβεννυμι*, to extinguish.

ASCARIDES, in medicine, a species of worms, very slender, found in the intestinum rectum, chiefly of children, and frequently voided with the feces. They often adhere to the fundament, and are sometimes even pendent from it.

The word is Greek, and derived from *ασκαρίζω*, to leap; because of their continual motion, which causes an intolerable itching.

ASCENDANT, or ASCENDING Line, in genealogy, is understood of ancestors, or such relations as are nearer the root of the family.

ASCENDANT, in astrology, that degree of the equinoctial which is rising above the horizon in the East, at the time of the birth of any person; and by some astrologers is called the angle of the first house.

ASCENDANT, in astronomy, is a term used for such stars as are rising above the horizon in any parallel of declination.

ASCENDENS *Obliquus*, in anatomy. See *OBLIQUUS*.

ASC

ASCENDING Latitude of a planet, is when the latitude of the planet moves towards the North pole.

ASCENDING Node, is that point of the planet's orbit, which intersects the ecliptic in the projection, when the planet is moving towards the North. See **NODE**.

ASCENDING Signs, in astrology, are those which are arising from the nadir, or lowest part of the heavens to the zenith.

ASCENDING Vessels, in anatomy, those which carry the blood upwards, as the aorta ascends, and vena cava ascendens.

ASCENSION, in a general sense, implies a moving upwards.

ASCENSION, in astronomy, is the rising of any celestial object above the horizon.

Right ASCENSION, in astronomy, is an arch of the equinoctial contained between the vernal equinox and the meridian, passing through the center of the sun, planet, or star.

The rule for finding the sun's right-ascension, having his longitude and greatest declination given, is this :

As radius,
Is to the cosine of the greatest declination,
So is the tangent of the sun's longitude,
To the tangent of right ascension required.

The rule for finding the right-ascension of a star, having the longitude and latitude given. Say,

As radius,
Is to the sine of longitude,
So is the tangent of latitude,
To the tangent of an arc, which call *a*.

Then, if the longitude be in a northern sign, with north latitude, or in a southern sign, with south latitude, subtract the first arc *a* from the obliquity of the ecliptic, for a second arc *b*. Then say,

As the sine of the first arc *a*,
Is to the sine of the second arc *b*,
So is the tangent of longitude,
To the tangent of right-ascension required.

But when the star's longitude and latitude are of different denominations, take the sum of the first found arc *a*, and the obliquity of the ecliptic, for the second arc *b*. Also note, when the difference is taken, that if the obliquity of the ecliptic be greater than the first arc *a*, the right ascension will be on the contrary side of the equinoctial point than the longitude is reckoned from.

The mean right ascension of any star may be readily found in the catalogue of its respective constellation, by adding or subtracting the annual variation in right ascension from the right ascen-

ASC

sion there found, according as the time required is before or after the year 1770 : and if you would have the apparent right ascension, apply the equation of aberration to the mean right ascension, and you have the apparent.

EXAMPLE.

Suppose the apparent right ascension of α Aquila be required, November the 29th, 1764.

Mean right ascension from catalogue
of Aquila, for the beginning of the
year 1770 $\quad\quad\quad = 328\ 29\ 27$

Annual variation $46''\ 27$, therefore, in
5 years and 32 days, it amounts to $\quad\quad\quad = 0\ 3\ 56$

Which subtracted from the right ascen-
sion for 1770, leaves the mean right
ascension for the year 1764, on No-
vember the 29th $\quad\quad\quad = 328\ 25\ 31$

Then in the table of aberration under
Aquila, and against Nov. 26, you
find $13''\ 1$; and proportioning for
the 3 days, you have $13''\ 9$ $\quad\quad\quad 0\ 0\ 13\ 9$

Which having the negative sign pre-
fixed, must be subtracted from the
mean right ascension, and you have
the apparent right ascension $\quad\quad\quad = 328\ 25\ 19\ 1$

To find the apparent right ascension of a planet, by observing with a good regulator the time of the transit of a star and the planet over the meridian.

RULE.

Find the apparent right ascension of the star, as directed before; then subtract the time of the passage of the first from that of the last, and turn the difference in time into degrees, minutes, and seconds of a circle; then if the planet passed the meridian first, subtract the difference in time turned into degrees, from the star's apparent right ascension, and the remainder is the planet's right ascension required; but if the planet passed the meridian the last, then the sum is the right ascension required.

EXAMPLE.

November the 29th, 1764, at the Royal Observatory at Greenwich, α Aquila passed the meridian (by a regulator adjusted to sidereal time) at $19^h\ 38'\ 48''$, and the moon passed the same day, by the same regulator, at $22^h\ 14'\ 8''$; therefore the difference in time is $2^h\ 35'\ 20''$, which turned into degrees, equals $40^\circ\ 50'\ 0''$. The apparent right ascension of α Aquila at the time of its passage, is found (as above) to be $328^\circ\ 25'\ 19''\ 1$, therefore adding $40^\circ\ 50'\ 0''$, the difference of the times of their transits, (because the moon passed last) we have $369^\circ\ 15'\ 19''\ 1$; which because it exceeds 360° , the whole circle, we must subtract 360, and the

the remainder is $9^{\circ} 15' 19''$, i, the apparent right ascension of the moon required.

To find the right ascension of the sun, planets, stars, &c. mechanically on the globe, armillary sphere, &c. see *GLOBE*, &c.

Oblique ASCENSION, is an arch of the equinoctial, comprehended between the vernal equinox, or point aries, and that point of the equinoctial line which rises with the planet or star.

When the latitude of the place and declination of the object are of the same name, that is, both north, or both south, then the difference between the right ascension and the ascensional difference will be the oblique ascension: but when of contrary names, their sum will be the oblique ascension required. Note, That if the sum exceeds 360° , the excess above is the oblique ascension; and when the ascensional difference is greater than the right ascension, add 360° to the right ascension, and then subtract the ascensional difference therefrom, and the remainder is the oblique ascension required.

ASCENSIONAL Difference, in astronomy, is the difference between the right and oblique ascension, which is found thus; Having the latitude of the place, and the declination of the planet or star, given,

Say, As the cotangent of latitude,

Is to radius,

So is the tangent of declination,

To the sine of the ascensional difference.

The ascensional difference thus found by trigonometry, is always equal the time the sun rises before or after 6 o'clock; therefore, if it be turned into time, and added to 6 hours when it rises before 6 o'clock, or subtracted when after 6 o'clock, we shall have the length of the semi-solar day. Note, That if the star or planet have no declination, they can have no ascensional difference, because when the sun or star are in the equinoctial, their oblique ascension and right ascension are the same.

ASCENT, in a general sense, implies the motion of a body upwards.

ASCENT of Fluids, is particularly understood of their rising above their own level, which is caused either by attraction, pressure, elasticity of the air, the force of pistons in pumps, &c. There are various experiments for proving the ascent of fluids by attraction; thus, if a tube be filled with sand, or sifted ashes, well pressed together, and one end of it be placed in a vessel of water, the water will be attracted by the sand, or ashes, and rise to a great height above that in the vessel. Or if any part of a piece of cap-paper, sponge, bread, sugar, pen, or several other substances, be wetted, the water will ascend or descend, and therefore propagate itself to the other parts by the power of at-

traction: This is likewise the cause of the ascent of spirit of wine, oil, melted tallow, or any other unctuous body into the wick of a candle. Nor is it unreasonable to think, that this is also the cause of the ascent of sap in trees, and of the various secretions of fluids through the glands of animals, and of several other effects in nature. See *ATTRACTION*, *Capillary TUBE*, *FLUID*, &c.

ASCENT of Vapours. It cannot be denied, but that the air is at all times more or less full of humid particles, as appears by their falling in an exhausting receiver, producing the halo. It is no less certain, that more moisture will be taken up and imbibed by air in motion, than air at rest; as is evident from the drying of linen and other things that are wet, much sooner when there is a gale of wind, than in calm weather. Besides, Dr. Halley's Experiments related in the Philosophical Transactions, put this matter past all doubt.

This gentleman, in order to account for the circulation of vapours, caused an experiment to be accurately made by the operator to the Royal Society at Gresham College, whereby the quantity of water raised and carried off in vapour from the surface of stagnate water, in a place as free from sun and wind as might be, was determined to be exactly eight inches deep or perpendicular in a year. This fell very much short of the quantity of rain found by the French academicians to fall in a year at Paris, viz. full nineteen inches perpendicular: and shorter still of the observations of Mr. Townley; who, at the foot of the Lancashire hills, lying in the neighbourhood of the Irish sea, found there fell in a year above forty inches of water perpendicular. So remarkable a difference makes it evident, that the sun and winds are the principal causes of the evaporation of fluids; the one to raise the vapour, and the other to carry it off and disperse it.

The doctor, in the same course of observations, takes notice of the vapours seeming at sometimes to adhere or hang about the surface of the fluids whence they rise, clothing them as it were with a fleece of vapourish air; at which times the evaporation appeared to be very little, by the small quantity of water then lost in twenty-four hours: and as this was observed to happen commonly when there was very little wind stirring, had these experiments been made in a place fully exposed to wind and sun, the expence of rising vapour would have been found to compensate at least the ordinary return of rain for a supply, as later experiments have sufficiently evinced.

And here it may be observed, that in still weather, when this fleece of vapourish air happens to be lodged in greater quantities near the surface of the water, both it and all objects thereon seem to be considerably raised, and even to lie in a level above the land. This can proceed only from the

refraction or bending of the rays of light, coming out of a medium of one degree of density into one of another; as may be exemplified at any time by pouring a quantity of fair water into a basin, which will then shew a piece of money, lying at the bottom, to an observer, from whom it was before screened by the brims of the vessel: by this experiment it will, to appearance, be raised about one third of the water's depth.

In still and sultry weather, when the sun-beams seem to act with a great, a general, and an equal force, on both the land and water, the rise of vapours is then observed to be more dull and languid. When they gleam as it were from behind, or through a cloud, and there is something of motion in the air, or a wind abroad, they rise in greater plenty. And in very hot climates, as Dr. Halley informs us, they mount in such abundance, that in St. Helena, lying in latitude sixteen degrees south, his glasses for observation were very often and very soon covered with water. And even in hot weather, in our own climate, the dews, which are no other than vapour condensed, are found sufficiently copious. Morning and evening, in that season of the year when the sun is not far above the horizon, the rising of mists from rivers, pools, and moist places, is frequently very visible, and is generally the forerunner of a sultry day. As the sun gains a greater height, the continued rise of the vapour is indeed not so apparent; but as the cause of their rise, viz. the heat, increases, there is no room to suspect, but that the effect is still proportionable to it.

It has been matter of dispute among naturalists, how the waters which form the clouds, and which descending, often deluge over vast tracts of land, come to be exhaled from the earth and suspended in a fluid so much lighter than water, as is the air. Some have imagined, that particles of fire, separated from the sun-beams, adhering to those of water, make together little masses of matter lighter than air, and which therefore rise therein till they come to such a part of the atmosphere as is specifically, or bulk for bulk of the same weight with themselves; there forming a thin cloud. And they suppose that rain is produced by the separation of those particles of fire, on occasions, from them; whereupon they coalesce, and then descend according to their own gravity, in drops of rain or dews.

This hypothesis, as Dr. Desaguliers justly observes in the Philosophical Transactions, is not without objections. As first, fire has never yet been proved to be a distinct element, or a particular substance; and the change of weight of bodies in chemical preparations heretofore presumed to rise from the adhesion of particles of fire, is proved by Dr. Hales, in his Vegetable Statics, to proceed from the adhesion of particles of air, which he has

there shewed to be absorbed by some bodies in good quantities, while it has been generated as fast by others; and that it may even be absorbed and generated successively by the same body under different circumstances. Secondly, Should the above-mentioned supposition be allowed, the fiery particles joined with the watery must be of some considerable bigness, and a person passing through a cloud, in ascending a hill, must be sensible of an extraordinary degree of warmth, which does not happen; for the vapour is there found to be really colder than rain itself falling at the foot of the hill. Besides, the manner in which these particles of fire might be separated from those of the water, is to be conceived from no phenomena yet observed: this theory therefore seems to be without foundation.

The second opinion concerning the rise and suspension of vapours is, that though water be specifically many times heavier than air, yet if the surface of it be increased by greatly diminishing the bulk of its particles, it cannot easily fall; since the weight of each particle is known to diminish in proportion to the cube of its diameter; whereas the surface to which the air resists, decreases only as its square: and this is sufficiently evident from the floating of dust, motes, and other light bodies, for a time therein, according as they are more or less minute.

This, however, will not explain the matter before us to satisfaction; because, though the increase of surface, the weight continuing the same, may in great measure hinder or retard the descent of very small bodies in the air, on account of its resistance to a surface, so much in proportion larger than their bulk, as aforesaid, it will for the same reason also impede their ascent therein. And 'tis known that the rising of dust, &c. in the air, is owing always to some outward force or motion applied; whereas vapours continue to rise as well in calm as windy weather, though not in an equal degree; neither do they always fall to the ground, or subside therein, when the wind ceases.

The third and most received opinion concerning this matter is, that by the action of the sun on the surface of the water, the aqueous particles become formed into spherules or bubbles, filled with an aura, a much finer air, or one highly rarefied, which thus becoming specifically lighter than common air, must therefore rise therein by hydrostatic laws, till such time as they meet with such an air as is bulk for bulk of their own weight.

This seems indeed to be the more probable supposition of the three; but to support it the following queries must be answered. How comes the aura, or subtle air within the bubbles to be at all specifically lighter than that without them; since the sun's rays must be admitted to heat the one equally with the other, and to beat with equal strength

on every part of the surface? Was it possible, that a rarer could be thus separated from the ambient fluid, what should hinder the cold air, which they needs must meet with in their ascent, from reducing these bubbles by contracting their contents; just as bubbles of soaped water commonly are, notwithstanding their tenacity is much greater than that of common water, when blown up by warm air from the lungs? And again, Was it reasonable to admit the rest of the supposition, a considerable difficulty will yet remain, viz. If clouds were thus constituted of shells of water filled with air, in its own nature elastic, why should they not always expand, when the circumjacent air is rarefied; and why not be condensed, when the weight of the atmosphere is there increased? This must be the natural consequence of this hypothesis, and the clouds would sink and rise in the atmosphere on every alteration of weight therein, without affording us any rain at all.

The doctor then plausibly proposes another, whereby he endeavours to account for the rise and suspension of the vapours in the atmosphere, from the elasticity and repellency observed in the steam of boiling liquors, capable of extruding either air or water from any vessel; and supposes the repellency of the particles of vapour to be always in proportion to their degree of heat. Hence he calculates the force of the vapours raised, taking with Sir Isaac Newton, the heat of boiling water at 34 (when the thermometer will shew our heat in the summer to be 5, in winter 2, and in spring and autumn 3 of those parts) and computes the height to which they accordingly must rise, comparing their elasticity with that of the air; on which heat has a much less effect; since that degree of heat which will expand water fourteen thousand times in boiling, will rarefy air only two thirds. He next considers the effects the cold found near and above the earth must have in condensing those vapours, and forming the clouds; and thinks that the distance they are observed to float at from the earth, in the various seasons of the year, corresponds with this theory.

But neither does this seem to be absolutely free from objections. For in distillations, the liquor boiling in the still, over a brisk fire, raises a great quantity of steam into the head, which endeavours to make its way immediately down the spiral pipe or worm, usually set in a tub of water, which, being cold when the still begins to work, condenses the rising vapour very fast. As the water next the worm comes to be heated by the continued rising of the burning steam, it condenses it indeed something slower; but yet when this water is become so hot, that a man can scarce bear his hand in it, it will nevertheless continue to condense them into a grosser fluid again.

Now as the mitigation of the heat of vapour,

and the lowering it from that of boiling water is generally attended with this effect, and as very little vapour is raised in the still before the liquor actually boils; it may be presumed, that the repellency of the particles of steam, under the degree of a boiling heat, can be but inconsiderable in promoting the rise of vapours to any great height in the atmosphere, or of producing the thing proposed.

Besides, steam of any heat whatever, if it be not some how confined, and caught as it were by some object near at hand, but being let into the air loose, like that rising from a seething-pot, or flaking lime, as far as we can trace it, that is, so long as it continues visible, does not by its motion shew any great disposition or tendency towards rising steadily, briskly, or the shortest way, into such part of the atmosphere as may be of equal gravity therewith: but it rather seems vaguely to fly hither and thither, till it can be absorbed and received by the air, thereby warmed in the same manner as the breath from the lungs and other humid vapours are.

It might be also suspected, that the repellency which should give the particles of water their first rise into the denser and circumambient air, would increase in air more rare, in their ascent, and defeat, and by their undue separation prevent their being ever condensed in rain. Besides, as the pressure of the denser air near the earth is not able to reduce them into so close a contact as to form drops of water there, it is not likely that in a rarer medium this should be done with more success.

For want therefore of a more perfect theory of this part of our meteorology, we must at present, in good measure, content ourselves with observed facts. And it being evident, that rare and warm air, together with what humid particles it shall at any time imbibe (and which from the constant heat of the sun must necessarily constantly be done, and that in very great plenty) will emerge and swim in air that's dense and cold, to such a part of the atmosphere as is of equal specific gravity therewith: and that whenever, for want of the superincumbent pressure, a part of its density shall be lost, it will let the watery particles fall, and they being collected and assembled in good quantity, will at length perhaps form a floating cloud, and become visible, merely by the reflection of the rays of light, which, falling by various angles thereon, exhibits various colourings, and a multiplicity of forms, to the eye of an observer: or if its density shall continue to be still more diminished, it may be again resolved into its original water, and become an immediate shower of rain.

The sun shining with equal strength on the surface both of the land and water, will doubtless affect them differently: because a great part of his rays are reflected from the solid earth by the same angle in which they fall thereon, whereby the air will

will always be more rarefied over this, than over the water, which absorbs most of them, and reflects but few: of consequence then the light air will mount, and continue to rise over the land, and the dense and vaporous air from sea will croud after it, to make good the deficiency; as in the case of the land and sea-breezes; and hence abundant matter will probably there be collected towards the formation of a cloud. See CLOUD.

ASCETICS, a name given to those who exercise an extraordinary degree of piety or virtue: such were the Esseni and Pharisees amongst the Jews, and the Stoics among the Heathens. In the primitive times of christianity, it was applied to those who lived a life of more rigid and austere sanctity, continually exercising themselves in the difficult and painful graces of self-denial and mortification, foregoing society, and wearing out their days in solitude and devotion. It was afterwards in a great measure laid aside, being seldom applied to any, except monks and hermits.

ASCII, in geography, are they who inhabit the torrid zone; because twice every year they have no shadow, which is, when the sun's declination is equal and similar to the latitude of the place.

The word is compounded of the Greek, *α*, priv. and *σκια*, a shadow.

ASCITES, in medicine, the same with dropsy. See DROPSY.

ASCLEPIA, in antiquity, a festival of Æsculapius, the god of physic; and observed particularly at Epidaurus.

ASCLEPIAD, in ancient Greek and Latin poetry, was the name of a particular kind of verse, which consisted of four feet, composed of a spondee, a choriambus, and two dactyls; or, which is the same thing, of a spondee, a dactyl, a long syllable, and then two more dactyls; as for instance,

Terrarum dominos evabit ad deas.

HOR.

ASCLEPIAS, swallow-wort, in botany, a genus of pentandrious plants; the flower is monopetalous, reflexed, and divided into five parts. In the center is situated five nectariums, encompassing the generative parts; these have horns which turn toward the stamina. It hath five filaments, which are scarce visible, topped with the same number of antheræ; these are situated between the nectariums. It hath two oval acuminate germen supporting two styles hardly discoverable, crowned with little stigmas; the germen afterwards becomes two large oblong acuminate pods, opening with two valves in one cell, which is filled with a number of imbricated seeds crowned with down. There are various species of asclepias; the officinal fort, called also hirsundinaria and vincetoxicum, grows naturally in the south of France, Spain, and Italy, and is

accounted a great counter-poison. The root of this plant is composed of many strong fibres, which are connected at the top (like those of asparagus), from which arise many stalks in number proportional to the size of the roots; these grow near two feet high, and are very slender at the top. The leaves are oval, ending in a point, and placed opposite by pairs. The flowers are white, growing in umbels near the top of the stalk, from which are sent out smaller umbels: the flowers appear in June, and the seeds ripen in September. Its roots and seeds are most in use, and recommended for their drying and warming qualities, which rank them among the alexipharmics and cephalics; and formerly an extract and a distilled water was made from this plant, but in the present medical practice it is much in disuse. To this genus Linnæus has added several species of the apocorum of Tournefort.

ASCLEPIODOTÆANS, in ecclesiastical history, a sect of heretics that appeared in the time of the emperor Heliogabalus, and so called from their leader Asclepiodotus, the first who taught that Jesus Christ was a mere man.

ASCORDRUTÆ, in ecclesiastical history, a sect of Christians in the second century, who placed all religion in knowledge, and under pretence of inward and spiritual worship, rejected every external and corporeal symbol.

ASCOLIA, in antiquity, a festival celebrated by the Athenian husbandmen in honour of Bacchus, to whom they sacrificed a he-goat, because that animal destroys the vines.

The word is Greek, and derived from *ασκος*, a bottle; it being customary at this festival to form the victim's skin into a kind of bottle, which was filled with oil and wine, and fell to the share of him who first fixed himself upon it with one foot.

ASCUS, in natural history, the pouch, or bag of the opossum. See OPOSSUM.

ASELBES, a name given by some to the millipedes. See MILLIPEDES.

ASH, *fraxinus*, in botany, a genus of polygamious trees, of which there are six species. The common ash grows to a tree of a considerable size. The leaves of this sort are pinnated, and generally contain four or five pair of lobes or folioles, which are placed opposite in pairs, ovated, acuminate, and slightly serrated at their edges, and are terminated by an odd one, of a dark green colour on the upper side and paler underneath. It hath hermaphrodite and female apetalous flowers, which grow at remote distances on the same tree, and sometimes on different trees. The hermaphrodite flowers contain two erect filaments, topped with upright oblong quadrifid antheræ. In the center is placed an ovate compressed germen, supporting an upright cylindrical style, crowned with a bifid stigma: the ovary afterwards becomes a seed vessel, containing a membranaceous lanceolated seed, shaped like

like

A S H

like a bird's tongue ; the female flowers are like the male, except wanting the stamina. This tree is a very free grower, and is propagated by sowing the keys (commonly so called), that are ripe about the latter end of October or November, at which time they should be gathered from the straightest and most thriving trees, rejecting those that grow on small or decaying trees ; having prepared a bed of fresh earth, which should be well dug and cleansed from noxious weeds and roots : a small bed will be sufficient to raise a great quantity of trees ; the seeds should be sown tolerably thick, and covered about half an inch with earth. These seeds many times lay in the ground a year before they come up, especially if they are not sown till the spring ; in this case the bed should remain undisturbed, keeping it clean from weeds. When the plants come up, if the weather proves dry, watering them now and then will greatly promote their growth, observing not to let any weeds grow amongst them ; if they make good progress in the seed-bed, they will be fit to transplant in the nursery the succeeding autumn, at which time there should be a piece of ground well prepared to receive them. When the leaves begin to fall off, it is the proper time for their removal, which should be done carefully with a spade, and not drawn up (as some injudiciously have practised) to the great detriment of the plants. When they are taken up, shorten the downright or tap-roots, and plant them about three feet row from row, and about a foot distance in the row, well closing the earth to their roots. In this nursery they should remain two or three years, observing to trim up the side-branches in winter, and dig the ground between the rows, after which time you may remove them where they are to remain for good. Where there are plenty of ash trees, a supply of self-sown plants may be had, especially in hedges, where they are protected from cattle by bushes, &c. In such places the plants will come up and thrive ; but they should not be suffered to grow in hedge-rows, as the ash robs every plant of its nourishment that is within reach of its roots ; nor should ash trees be permitted near pastures, for if any of the cows eat of the leaves or shoots, all the butter which is made of their milk will be rank and of little value. This tree will grow upon almost any soil ; but the better the soil is, the more the tree will increase in bulk. If they are designed for a particular plantation, their proper distance may be about eight feet each way, and planted in quincunx order ; and after they have been planted a year or two, every other tree may be cut down, reserving the most likely plants. Those which are cut down should be left six or eight inches above ground, when they will make several strong and vigorous shoots, which in a few years will be useful for making coopers hoops, and divers other purposes : the other trees which are left are designed for

A S P

timber, the number of which may be lessened as the trees advance in magnitude, observing to reserve the most promising for timber of the largest size. If a wood of these trees are properly managed, it will turn out greatly to the owner's advantage ; for by the underwood, which will be fit to cut every seven or eight years for the uses above-mentioned, and the stock preserved for timber, it certainly would be well worth while, where the land is not too dear, to make a plantation of ash trees. The timber of this tree is excellent for various uses, as for oars, ploughs, axle-trees, harrows, blocks for pulleys, coach-making, wheels, and divers other purposes. The best season for felling the ash is in December or January, for if it is done either too soon in autumn, or too late in the spring, the timber will be subject to be infested with worms and other insects ; but for lopping the pollards the spring is to be preferred. The other species of ash may be propagated by inoculating them on the common sort, upon which they will all take very well, and become harder than upon their own stock ; but those budded trees never grow so large as those raised from seeds, nor will the stock and bud keep pace in their growth, so that there will be a considerable difference in the size of the stem, and above the place of inoculation ; but as few of the foreign kinds have yet arrived at an age to produce seeds in England, the nursery-gardeners have been obliged to propagate them by budding, unless they can procure a sufficient quantity of seeds from the countries they are natives of. The seeds of the common ash are accounted good in the jaundice, pleurisy, and the stone, but in the present medical practice are much disused.

ASHES, *cineres*, the earthy particles of wood, coal, and other combustible substances, remaining after they are consumed by fire. These, if produced from a vegetable, are of a whitish colour, and contain a considerable quantity of fixt salt, blended with the terrene particles, and when boiled with fair water yield a lixivium of an acrimonious alkaline taste. Ashes of all kinds contain a very rich fertile salt, and are the best manure of any for cold wet lands : they are also of considerable use in making lixiviums or lyes for the purposes of medicine, bleaching, and for sugar-works, and are distinguished by various names, as *poi-ashes*, *pearl-ashes*, &c. which see.

ASIATIC, something peculiar to Asia.

ASIATIC Style. See STYLE.

ASIDE, in the drama, something said by an actor, which some, or even all the other actors present, are supposed not to hear ; a circumstance justly condemned as being unnatural and improbable.

ASINUS, in natural history, the ass. See ASS.

ASP, in natural history, a species of serpents often mentioned by the ancients, but without any accurate

accurate description of it. Some say it is of the size of a common snake, but the back broader; and the neck swells greatly when the creature is angry. Some assert that their teeth grow exceeding long, and stand out of their mouths like those of the boar; but this seems to be fabulous. However, it may be true, that two of the longest are hollow, and that they are those which contain the venom. They are generally covered with thin pellicles, which slide down when the serpent bites. The skin is said to be covered with scales, which are redder than those of any other serpent; but others affirm they are of very different colours. Some say they are two cubits long, others four, and others again five; Peter Kolben affirms he has seen them several ells in length: so that, in short, nothing certain can be known of the asp. It is undoubtedly a native of Africa: and it was by the bite of one of these serpents that Cleopatra is said to have ended her days.

Seba gives the name of asp to several serpents, the first of which is said to be found in Egypt, and is spotted with black. The skin is of a reddish ash-colour, marked with black spots; whereas those on the back nearly resemble eyes. The head is of a dark brown, surrounded with a white colour; and the scales of the belly are white, adorned with a reddish border. He has also an American asp, which nearly resembles this in every respect.

The Java asp is of a sea-green, with a sharp mouth, and a long head covered with scales on the fore-parts. The other scales are also of a sea-green colour, with white edges, except under the belly, where they are of a light green, and separated from the rest by two white streaks running like furrows along the sides.

The Surinam asp is of a bright green colour, with blackish spots; but the belly is of an ash-coloured red, and the head is of a deep green; the eyes are lively, and the tail is terminated with sharp points. *Broske's Natural History.*

ASPALATHUM. See **LIGNUM RHODIUM.**

ASPALATHUS, African broom, in botany, a genus of plants bearing papilionaceous flowers, with obtuse moon-shaped wings, containing ten stamina, with a single style; the ovary becomes an oblong pod, containing one or two reniform seeds. There are three species in this genus, which are all natives of the country about the Cape of Good-Hope.

ASPARAGUS, in botany, a genus of farmentaceous plants, whose flower is rosaceous, composed of six petals, which spread open, and are reflexed at the top, and containing six filiform filaments topped with roundish anthers: from the center of the flower ariseth the pistil, which afterwards becomes a soft, round, red berry, of three cells, in each of which are lodged one or two seeds.

There are several species of asparagus, but the

fort which is best known is the common asparagus, of which great quantities are raised to supply the London markets, for at least half the year. The garden-asparagus is propagated by sowing its seeds; in the choice of which there should be care taken previously to mark the buds of an old bed, the largest and straightest to be reserved; which buds, when they have branched, may be fastened to stakes to preserve them from being broken down. Most of these buds will produce in autumn great quantities of red berries, which should remain on the branches till the stalk begins to decay; then strip off the berries into a tub, where they may lie in a heap to sweat for about three weeks or a month, by which means the outward husks will be rotten; then fill the tub with water, and break all the husks by squeezing them between your hands: these husks will swim upon the water, but the seed will sink to the bottom; so that, by pouring the water off gently, the husks will be carried along with it, and, by putting in fresh water two or three times, and stirring it up, the seed will be entirely clean; then spread the seed on a matt, and exposing it to the sun and air until it is perfectly dry, it then may be put by, and reserved till the time of sowing, which is in February, when a bed of good rich earth must be prepared, whereon the seed may be sown, but not too thick; after which tread the seed into the ground, and rake it smooth over. The succeeding summer the bed must be constantly kept clear from weeds; and towards the latter end of October, the haulm should be taken off, and a little rotten dung should be spread over the bed to preserve the young buds from being damaged by frosts, &c.

The roots in the following spring will be fit to be planted where they are to remain. A proper piece of ground must therefore be prepared, by well trenching it, and burying a large quantity of rotten dung, taking out all large stones, &c. which being handomely levelled, will be fit to receive the plants. The time for planting these roots depends on the moisture or dryness of the soil, so as to make a month's difference. If very dry, plant in the beginning of March; but if wet land, it is better to defer the planting till April; about which time the plants are beginning to shoot. The season being come, the roots should be taken up carefully with a three-pronged fork, commonly called an asparagus-fork, shaking them out of the earth, and separating them from each other, observing to lay their heads even for the more convenient planting them, which must be done in the following manner: The plot of ground being levelled, begin at one side thereof, ranging a line very tight across the piece, which will be a direction to cut a straight trench about six inches deep, in which the roots are to be placed, spreading them with the fingers, and setting the buds upright, so as to be about two inches below the surface of the ground, and twelve

twelve inches asunder; then fill up the trench and smooth the surface; then remove the line a foot farther back, and make a trench in like manner, laying the plants therein as before-directed, and continuing the same distance from row to row till the whole is finished, observing between every four rows to leave the distance of three feet for an alley to go between the beds to cut the asparagus, earthing them up, &c.

The plot being finished and levelled, a small crop of onions is generally sown on it, which hurts but little the asparagus. Another method is sowing the seeds where the plants are to stand for good, which is, instead of planting the roots, as before directed, to make holes at a foot distance and drop two seeds in each; these holes should not be above half an inch deep; then cover the seeds, and so continue on from row to row at the same distance as in planting the roots, if it is designed to stand for the natural season of cutting; but if it is to be taken up for hot-beds, there may be six rows planted in each bed, and the distance in the rows need not be more than nine inches. This should be performed in February, because the seeds lie long in the ground. As the roots of asparagus always send forth many long fibres which run deep in the ground, so when the seeds are sown where they are to remain, these roots will not be broken or injured as those must which are transplanted; therefore they will shoot deeper into the ground, and make much greater progress, and the fibres will shoot out on every side, which will cause the crown of the root to be in the center; whereas, in transplanting, the roots are made flat against the side of the trench. When the asparagus is come up, the onions should be hoed; but this method must be done in dry weather, that the weeds may die as fast as they are cut up. This work must be repeated about three times, which, if well done, and the season not too wet, will keep the ground clear from weeds until the onions are fit to be pulled up, which is commonly in August. When the onions are drawn off, the ground must be cleared, except the asparagus haulm, which should remain till it decays. This haulm should be cut off with a knife, leaving the stems two or three inches above ground, which will be a guide to distinguish the beds from the alleys: then with a hoe clear off the weeds into the alleys, which dig up, burying the weeds in the bottom, and throw the earth on the beds, so that the beds may be about five inches above the level of the alleys. In this manner it may remain till spring, when the beds must be hoed over to destroy the young weeds. In the following autumn dig up the alley again, as was before directed, earthing the beds rather thicker. The third spring after planting, some of the asparagus may be cut for use; therefore, when the buds are preparing to shoot above ground, the beds should be stirred up

with a fork made purposely, observing not to go too deep, lest the head of the root is wounded; then rake the bed smooth, which will destroy the young weeds. When the buds appear about three or four inches above ground, they may then be cut for use; but it should be done sparingly, only taking the large buds, and suffering the small to run up, which is absolutely necessary for the future welfare of the roots.

The manner of dressing asparagus beds is every year the same, viz. Keeping them from weeds, digging the alleys in October or November, and forking the beds in the spring, &c. only observe every other year to lay a little rotten dung all over the beds, and burying some in the alleys, also, at the time of digging them up; this will preserve the ground in good heart to maintain the roots with vigour; and by this management a plot of good asparagus may be continued for ten or twelve years in cutting, and will produce good buds. The alleys being proposed three feet, which is wider than is commonly practised, a crop of beans may be raised in each without prejudicing the roots of the asparagus; and by the beds they will be protected from the cutting winds in the spring.

Asparagus, by being planted about six weeks on a hot-bed (well prepared) before it is wanted, will produce very good crops; and by having a succession of these beds, asparagus may be raised for the table all the winter. The buds of this plant are extremely diuretic, which is discoverable by the smell of the urine; but the roots are yet more so, because they have more of the salt from whence they derive that quality, than any part which grows above ground; to which it cannot rise in such plenty, as the root itself receives it from the earth; and this may pass for a reason why most roots are more endued with this property than their plants. This is deservedly reckoned one of the five opening roots, and is good in all compositions intended to cleanse the viscera; especially where obstructions threaten the jaundice or dropsy. There are several sorts of asparagus, two of which are wild. One is distinguished by C. Bauhine, *sylostetris tenuissimum folia*, which grows about Montpellier in France, differing little from the garden sort; the other, *petraea et corruda foliis acutis*, growing in some parts of Italy; the tops of which are eaten as ours here, having also ascribed to them the same virtues.

ASPECT, among gardeners, signifies the same with exposure. See the article EXPOSURE.

The word is formed from the Latin, *aspectus*, which is derived from *aspicio*, to view.

ASPECT, in astronomy, signifies the situation that each planet or star bears to another, and is usually divided into five by astronomers in almanacks, &c. The first is called Sextile, and marked thus *, signifying that the planets or stars are 60 degrees distant from each other. The second is called

is much slower, and he is sooner tired. The asf brays in a very disagreeable manner; the she-asf has a more shrill and piercing cry.

Of all animals that are covered with hair, the asf is least subject to vermin; which may perhaps proceed from the hardness and dryness of his skin; and for the same reason, he is less sensible of the strokes of a whip, and the stinging of flies, than a horse. The teeth fall out, and grow at the same age, and in the same manner as in a horse, and he has the same marks in his mouth. Asfes generally breed in May and June, and in the tenth month the milk appears in the dugs of the female; but she does not foal till the twelfth month; seven days after which, she is ready for the male again. She always brings forth one at a time; at least there are few instances to the contrary.

The asf, like the horse, is three or four years in growing, and will live till twenty-five or thirty. They sleep much less than a horse, and never lie down for that purpose, unless they are very much tired. In general, they have much better health than a horse, and are subject to fewer diseases.

Travellers inform us, that there are two sorts of asfes in Persia, one of which is used for burdens, they being slow and heavy; and the other, kept like horses, for the saddle; for they have smooth hair, carry their heads well, and are much quicker in their motion; but when they ride them, they sit nearer their buttocks than when on a horse. They are dressed like horses, and are taught to amble like them; but they generally slit their nostrils to give them more room for breathing. Dr. Russel likewise tells us, they have two sorts in Syria, one of which is like ours, and the other very large, with remarkable long ears; but they are both put to the same use, that of carrying burdens.

The onager, or wild-asf, has been, by some authors, confounded with the zebra, but very improperly, the latter being a distinct species; for the onager is not streaked like the zebra, nor is his shape so beautiful. Some have also been of opinion, that the wild asf is not a distinct animal from the common asf; but all judicious travellers that have taken notice of them, affirm the contrary. They are said to be very swift; and when they see a man, will make a bound, and immediately fly away: so that the only method of taking them, is by traps and gins. They have much the same shape as common asfes, but are of a brighter colour, and a white list runs from the head to the tail. Of the hide of these asfes, and particularly of that part next the rump, they make that excellent leather which we call shagreen, and which is put to so many curious uses.

Asfes Milk, the milk of the animal described in the preceding article; and greatly esteemed in consumptions, &c.

ASSA DULCIS, and *FOETIDA*. See *Asa*.

ASSARON, or *OMER*, a measure of capacity, in use among the Hebrews, containing five pints.

ASSART, *Assertum*, in law, an offence committed in a forest, by pulling up the trees by the roots.

This is a greater trespass than waste; though a person may sue out a licence to assart ground in a forest; that is, to render it arable; and hence some districts are called assarted lands; and formerly the owners paid assart rents to the crown for them.

ASSASSIN, a person who kills another secretly, or by attacking his enemy unprepared. It is also applied to a person who, for the sake of some stipulated reward, undertakes to murder a person to whom he is a stranger, in order to revenge the quarrel of another.

ASSAULT, in law, a violent injury offered to a man's person, being of a higher nature than battery; for it may be committed by offering a blow, or pronouncing a terrifying speech.

Thus, in case a person threatens to beat another, or lies in wait to do it, if the other is hindered in his business, and receives loss, it will be an assault for which an action may be brought, and damages recovered.

Not only striking, but thrusting, pushing, throwing stones, or even drink in the face of any person, are deemed assaults. But in all these cases, a man may plead in his justification the defence of his person or goods, father, mother, wife, master, &c.

ASSAULT, in the military art, implies a furious effort made to carry a fortified post, camp, or fortress, wherein the assailants do not screen themselves behind any works: while the assault lasts, the batteries cease firing for fear of killing their own men.

ASSAY, in metallurgy, the trial of the goodness and purity of metals and metallic substances.

ASSAY Oven, or *Docimassical Furnace*, a furnace used in assaying metals.

It is constructed in the following manner: 1. Make with iron plates, a hollow quadrangular prism, H, H, (Plate XII. fig. 2.) eleven inches broad, and nine inches high, ending at the top in a hollow quadrangular pyramid I, seven inches high, and terminating in an aperture seven inches square. But this prism must be closed at the bottom with an iron plate A, which serves as a basis. 2. Near the bottom make a door A, three inches high, and five inches broad, leading to the ash-hole. 3. Above this, and about six inches from the base, make another door C, forming the segment of a circle, four inches broad at its base, and three inches and a half high in the middle. 4. Fasten three iron plates H, H, H, on the fore part

part of the furnace; let the lowermost of these plates, which is eleven inches long, and half an inch broad, be fastened with rivets to the bottom and fore part of the furnace, in such a manner, that there may be a groove so wide, between the upper edge of the said plate, and the side of the furnace, that the sliders B, B, of the lower door, may be moved easily backwards and forwards therein, by means of the handles O, O: these sliders must be made of a thicker iron plate than the other parts of the furnace. The second iron plate must be also fastened with rivets in the space between the two doors, and directly parallel to the former, in such a manner, that both the upper and lower edge of it may form a hollow groove with the side of the furnace. The lower of these grooves serves to receive the upper edges of the sliders B, B, that shut the lower door: the upper groove is to receive the inferior edges of the sliders D, D, belonging to the door C. The third plate, which is like the first, must be riveted close above the upper door, in such a manner, that its lower side may form a groove with the side of the furnace. 5. Make two sliders D, D, to slide in the above grooves, by means of the handles O, O. In these sliders must be two holes near the top; the one, marked E, must be about one fifth of an inch broad, and one inch and a half long; the other, marked F, a circular aperture one inch high, and two inches broad. 5. Let five round holes one inch in diameter be bored in the furnace, two in the fore part marked G, G, and two in the back part, all at the height of five inches from the bottom, and each of them three inches and a half from the nearest side of the furnace: and a fifth hole K, at the height of one inch above the top of the upper door C. 7. Let the inside of the furnace be furnished with iron hooks, about three inches from each other, and projecting about half an inch, in order to fasten the lute, with which the inside of the furnace must be covered. 9. Let a moveable hollow quadrangular pyramid M, three inches high, be fitted to the upper aperture L, of the furnace; seven inches broad at the base, and terminating at top in a circular tube N, three inches in diameter, two inches high, and the upper diameter somewhat less than the bottom. This prominent tube serves to support a funnel or flue, fitted to it, and composed of iron plates, two feet high. This funnel is only necessary when a very strong fire is required. The pyramidal cover M, must have two handles P, P, fastened to it, in order to put it on, or take it off, as the operation may require. And to hinder this cover from being easily thrown down, let an iron plate be riveted to the right and left sides of the upper part of the furnace, and turn down towards the inside, so as to form a grove, into which the lateral edges of the cover may enter, and slide forwards and backwards at pleasure. A square ledge of thick iron plate

must be fastened to the top of the upper ledge of the lower door A, in order to support the grate and lute. The grate must be composed of small iron bars, half an inch thick, three fourths of an inch distant from each other, and placed edgewise on the ledge. The lute must be about three quarters of an inch thick, and composed of Windford loam, or French clay, moistened with ox blood diluted with water. In order to perform an operation in this oven, two iron bars an inch thick, and of a proper length, must be thrust through the four holes G, G, above described, in order to support the muffle introduced through the upper aperture of the furnace.

ASSAYING, the art of discovering how much pure metal is contained in any ore; or the proportion of the several ingredients in any mixed metal. For the methods of assaying the several metals, &c. see the articles **GOLD**, **SILVER**, **LEAD**, **COPPER**, &c.

ASSAYING of weights and measures, implies the examining the several weights and measures by the clerk of the market.

ASSAY-MASTER, an officer appointed by certain corporations, to make just assays of all gold and silver brought to him for that purpose, and make a true report thereof.

ASSEMBLY, in military affairs, implies the second beating of the drum before a march, on which the soldiers strike their tents, roll them up, and stand to arms.

ASSENT, *Assensus*, in a general sense, implies an agreement to something proposed or affirmed by another.

Royal Assent, the approbation given by the king to a bill in parliament, after which it becomes a law.

ASSIENTO, in commerce, a contract between the king of Spain and some other power for transporting negroes into the Spanish dominions in America.

The word is Spanish, and signifies a farm.

ASSIGN, in common law, a person to whom a thing is assigned or made over.

ASSIGNEE, in law, a person appointed by another to do an act, transact some business, or enjoy a particular thing.

Assignees may be appointed either by deed or by law: by deed, where the lessor of a farm assigns the same to another; by law, where the law makes an assignee without any appointment of the person intitled; as an executor is assignee in law to the testator, and an administrator to an intestate. But when there is an assignee by deed, the assignee in law is not allowed.

ASSIGNING, in a general sense, implies the making over the right of one person to another. In a particular sense, it signifies the pointing out of something, as an error, false judgment, or waste:

waste : but in these cases it must be shewn wherein the error is committed, where and how the judgment is unjust, and where the waste is committed.

ASSIGNMENT, in law, the transferring the interest one has in a lease, or other thing, to another person.

ASSISE, in old law books, is defined to be an assembly of knights and other substantial men, together with the justice, in a certain place, and at a certain time : but the word in its present acceptation, implies a court, place, or time, when and where the writs and processes, whether civil or criminal, are decided by judge and jury.

In this sense, assise is either general or special ; general, when judges go their respective circuits, with commission to take all assise ; special, when a commission is granted to particular persons for taking an assise upon one or two districts only.

By magna charta, justices shall be sent through every county, once a year, who, with the knights of the several shires, shall take assise of novel disseisin. With regard to the general assise, all the counties of England are divided into six circuits, and two judges are assigned by the king's commission to every circuit, who now hold the assises twice a year, in every county except Middlesex and the counties palatine. These judges have five several commissions. 1. Of oyer and terminer, by which they are empowered to try treasons, felonies, &c. 2. Of goal-delivery, which empowers them to try every prisoner in goal, be his offence what it will. 3. Of assise, which gives them authority to do right upon writs, brought by persons wrongfully thrust out of their lands and possessions. 4. Of nisi prius, by which civil causes come to an issue in the courts at Westminster, are tried in the vacation by a jury of twelve men, in the county where the cause of action arises. 5. A commission of the peace in every county of the circuit : and all justices of the peace and sheriffs are to attend upon the judges, otherwise they are liable to be fined.

ASSISE is also used in several other significations ; as 1. For a jury, where assises of novel disseisin are tried, and the pannels of assise shall be arraigned. 2. For a writ issued for the recovery of things immovable, of which a person and his ancestors have been disseized. 3. For an ordinance or statute : thus the assise of the forest is a statute concerning orders to be observed in the king's forest. 4. For a quantity of wheat, bread, &c. prescribed by the statute.

ASSISE of Novel Disseisin, is a writ that lies where a tenant in fee simple, fee tail, or for term of life, is put out and disseized of his lands, tenements, rents, common of pastures, common way, &c.

ASSISE of Mort d'Ancestor is a writ which lies

where a person's father, mother, brother, &c. died, seized of lands and tenements in fee, and after either of their deaths a stranger abated.

ASSISE of Utrum lieth for an ecclesiastic against a layman, or a layman against an ecclesiastic, for lands or tenements doubtful whether they be lay-fee or free-alms.

ASSIZE. See **ASSISE**.

ASSOCIATION, the act of associating, or constituting a society, or partnership, in order to carry on some scheme or affair with more advantage.

The word is Latin, *associatio*, and compounded of *ad*, to, and *socio*, to join.

ASSOCIATION of Ideas, is where two or more ideas constantly and immediately follow one another, so that the one shall almost infallibly produce the other, whether there be any natural relation between them or not.

When there is a real affinity or connection between ideas, it is the excellence of the mind to be able to collect, compare, and range them in order in its enquiries : but, on the contrary, where there is none, nor any cause to be assigned for their accompanying each other, but what is owing to mere accident or habit, the association is unnatural, becomes a great imperfection, and is too often a principal source of error or wrong deductions in reasoning.

ASSOCIATION, in law, is a writ or patent sent by the king, either of his own motion, or at the suit of the plaintiff, to the judges of assise, to have others associated with them to take the assise. Upon this patent of association, the king sends his writ to the justices of assise, commanding them to admit those that are so sent.

ASSONANCE, in poetry and rhetoric, is a term made use of to express a similarity of sound in the final words of any particular phrases, or verses, without their being exactly in rhyme ; thus, for instance, in the following lines of Spencer,

And thou, Menalcas, fraught with treachery,
Shouldst well be known for such thy villainy.

There is a jingle but no rhyme ; which is regarded in English as a very great fault, whether it happens in verse or prose. It was esteemed by the Romans as an elegance, and accordingly we meet with it very frequently in Cicero. It is still in use among the Spaniards, where a resemblance of sound serves instead of a proper and natural rhyme : thus, *ligera, cubierta, tierra, mesa*, are employed to answer each other as *assonant* rhymes, in regard they have each an *e* in the penultima, and an *a* in the last syllable.

ASSUMPSIT, in law, a voluntary or verbal promise, whereby a person undertakes to perform some agreement, or pay a certain sum to another.

Thus, where a man sells goods to another, the law makes the assumpsit ; and promises he shall pay for them.

ASSUMPTION, a festival in the Romish church, celebrated in honour of the miraculous ascension of the Virgin Mary, body and soul, into heaven.

The word is Latin, *assumptio*, and compounded of *ad*, to, and *sumo*, to take.

ASSUMPTION, in logic, is the minor or second proposition in a categorical syllogism.

ASSUMPTION is also sometimes used to imply a consequence drawn from the propositions which compose an argument.

ASSUMPTIVE Arms, in heraldry, are such as a person has a right to assume in consequence of some noble and gallant action.

ASSURANCE, or **INSURANCE**. See **INSURANCE**.

ASSURRITANI, in ecclesiastical history, a sect of heretics, who sprang up in Africa, during the reign of Constantius, and were a branch of the Donatists. See **DONATIST**.

ASTAROTH, or **ASHTAROTH**, in antiquity, a goddess of the Sidonians.

The word is Syriac, and signifies sheep, especially when their udders are turgid with milk. From the fecundity of those animals, which in Syria continue to breed a long time, they formed the notion of a deity, whom they called Astaroth, or Astarte. See **ASTARTE**.

ASTARTE, the singular of Astaroth, a goddess of the Sidonians, and called, in Scripture, the Queen of Heaven.

This deity is said to have consecrated the city of Tyre by depositing in it a fallen star: and hence, perhaps, came the notion of a star, or globe of light, which at certain times darted from Mount Libanus, near her temple at Phac, and plunged itself into the river Adonis.

Mr. Fourmont, who has endeavoured to trace most of the pagan divinities mentioned in Scripture, supposes the Sidonian Astarte or Astaroth, to be the same with the Rachel of the Bible; because the former in the Syriac language implies sheep, and the latter has the same signification in the Hebrew.

ASTATI, in ecclesiastical history, a sect of heretics in the ninth century, the followers of one Sergius, who renewed the errors of the Manichees.

The word is Greek, *αστατοι*, and compounded of *α*, priv. and *σταμι*, to stand firm; because they were remarkable for their inconstancy.

ASTER, starwort, in botany, a genus of plants producing a radiated flower, the disk of which is composed of several funnel-shaped hermaphrodite floscules, which spread open at the top in five parts, and contain five capillary filaments, topped with cylindrical anthers, with an oblong germen supporting a filiform style. The rays or border compose the female floscules, which are lanceolated and in-

dentated in three parts at the extremity, and are the same as the hermaphrodite in other respects, except wanting the stamina; the receptacle is plain and naked, and the seeds are of an oblong figure, oval at top, and winged with down.

There are various species of asters, some of which are perennial, and others which are annual; but the most beautiful and greatest in esteem is the China aster, commonly called the queen Margaret, of which there are three sorts; one with purple flowers, another with pink-coloured flowers, and the third with white flowers: of each of these sorts, there is a variety producing double flowers, which are most esteemed. These plants are raised on slight hot-beds in the spring, in order to forward their growth, so as to produce flowers early enough in autumn, that their seeds may be ripened. The common perennial sorts are increased by parting their roots in autumn, some of which are very troublesome to be eradicated, if suffered to run much, and are commonly called Michaelmas daizies.

ASTERIA, in natural history, a beautiful pelucid gem of variable colours, when viewed in different lights. It is generally known among jewelers by the name of cat's-eye. See **CAT'S-EYE**.

ASTERIA is also the name of an extraneous fossil, called in English the star-stone. See **STAR-STONE**.

ASTERISK, a mark or character in the form of a small star (*) placed over any word or sentence, to render it more conspicuous, or refer the reader to the margin, or elsewhere, for a quotation, explanation, or the like.

The word is a diminutive of the Greek, *αστηρ*, a star.

ASTERISCUS. See **BUPHTHALMUM**.

ASTERISM, in astronomy, the same with constellation. See **CONSTELLATION**.

ASTERN, in the marine, any distance behind a ship, or in direct opposition to that point of the compass which is a-head, and to which her stem points; as when north is a-head, south is a-sterne. See **A-HEAD**.

ASTHMA, in medicine, a painful, difficult, and laborious respiration, occasioned by an intolerable straitness of the præcordia, which, by impeding the free circulation of the blood through the lungs, endangers a suffocation.

The word is Greek, *ασθμα*, and derived from *αω*, to breathe.

There are several sorts of asthmas: one difficulty of breathing proceeds from corpulency, and a very full habit of body; and is most apparent after violent motion; but this is a slight disorder, and free from all danger. The next is the pituitous asthma, attended with a moist cough, and the bringing up pituitous matter; it attacks the patient at all hours, and in all positions of the body; and

is owing to a plenty of a viscid mucus stuffing the vesiculæ of the lungs, and hindering the free ingress and egress of the air through them. Another is owing to the convulsive contraction of the parts designed for respiration, and proceeds from various causes, both within and without the thorax; and this is called the dry, flatulent, or convulsive asthma.

The longer this disease continues, the more sharp and violent all the symptoms become. The patient's body grows more colicive, and the urine is thin and watery; most commonly the feet swell, then the hands, face, and back; there is a numbness of the arms; the countenance is wan and livid, or of a leaden colour: then comes on a little fever, which grows worse in the evening; the whole body is cachectic, with an cedematous swelling of the feet; there is a dropsy of the breast, or an ascites, or anasarca; at least there is a palsy on one side, or of the arm; or instead thereof, a palsy of the eyelids. This disease is likewise called by some, a suffocating asthma; by others the nervous asthma.

When the disease is recent, and is owing only to the spasmodic contraction of the præcordia, there are hopes of a cure; especially if the matter of the gout, ulcers, and exanthemata, are sent back to their proper seats. When the menses or hæmorrhoids, which were stopped, return, it yields relief, and if the disease was not too far advanced, perfect health. If it is inveterate, or ill-managed, it brings on a dropsy of the breast, obstructions of the lower belly, cedematous swellings of the feet, a cachexy, and an universal dropsy. In general, all convulsive asthmas portend a sudden exit, or suffocation; especially if there is a polypus of the heart; if it continues long, then the patient will die of the dropsy; in which case it will be soon fatal: when there is a slow fever, an unequal intermitting pulse, a palsy of the arms, a continual palpitation of the heart, little urine, a syncope or swooning, then death is at hand. Some are carried off by an inflammation of the lungs, and the more grievous the disease the more languid the pulse. The asthma, in old persons, continues till death: that which is caused by a dislocation of the vertebra cannot be cured till they are reduced. The more violent the accession, the longer it lasts, and the oftener it returns with a greater danger of suffocation.

In the paroxysm, because the body is generally bound, and the wind and humours are carried upwards, the speediest assistance is from emollient and carminative clysters.

If there is occasion, it may be repeated two or three times: afterwards use frictions of the feet, which have an incredible efficacy; also let them be put into warm water; for the feet are almost always cold. When there is a violent spasm about the

præcordia, hot fomentations are necessary, or bladders filled with hot milk, and applied to the part affected; likewise nervous liniments are very useful, rubbed in with a warm hand.

Out of the fit, if it proceeds from too great a congestion of blood about the breast, or from a polypus of the heart, bleeding in the foot will be proper, as also scarifications; in a suppression of the hæmorrhoids, leeches should be applied to the anus; as also gentle laxatives to cleanse the primæ viæ: likewise bodily motion, slender diet, and soft drink. If there are hypochondriacal or flatulent symptoms, then gentle laxatives will be the more necessary, together with clysters. When the menses or hæmorrhoids are suppressed, then nothing is better than the Bath waters, both for bathing and drinking; or the waters of Selters taken warm and mixed with milk.

When the asthma proceeds from the driving back some impure matter from the skin, or from the drying up of ulcers, and the humour is transfused to the nervous parts of the breast, then gentle diaphoretics will be necessary to send it back to the superficies of the body.

ASTRÆA, in mythology, the goddess of Justice. She was the daughter of Jupiter and Themis, and came down from heaven in the golden age; but when the manners of men became corrupt, she left the earth and returned to heaven.

ASTRÆA, in astronomy, the same with Virgo. See **Virgo**.

ASTRAGAL, in architecture, a small round moulding in form of a ring, serving as an ornament at the top and bottom of columns. Sometimes the astragal is put to separate the fascia of the architrave; in which case it is ornamented with beads and berries, chaplet-wise. It is likewise used above and below the lists, adjoining immediately to the dye, or square of the pedestal. See **COLUMN**.

ASTRAGAL, in gunnery, a round moulding, encompassing the cannon about six inches from its mouth.

ASTRAGALUS, wild liquorice, or milk-vetch, in botany, a genus of plants producing papilionaceous flowers, which contain ten filaments, nine of which are joined together, and one stands single, and topped with roundish antheræ: the germen is tapering, and becomes an oblong bilocular pod, containing a row of reniform seeds. It is said to be diuretic, and to increase the milk of nurses.

ASTRAL, in astronomy, is something belonging to, or connected with the stars; as astral year is the same as syderial year.

ASTRINGENTS, among physicians, such medicines as are of an astringent or binding quality.

The word is formed from the Latin, *ad*, to, and *stringo*, to bind.

Hoffman very judiciously observes, that astrin-gents are very proper to restore a tone and elasticity to the animal fibres, when debilitated by diseases, intemperance, or accident: but they are very seldom proper without a previous attenuation of the juices, and a course of deobstruent medicines; because obstructions are more firmly riveted, and the viscid juices circulated with more difficulty, when the diameters of the vessels are constricted by astringents.

ASTRORITES, the star-stone, in natural history; see the article STAR-STONE.

ASTROLABE, among the antients, was the same with what we now call an armillary sphere. It was also the name of a stereographic projection of the sphere, either on the plane of the meridian, equator, or any great circle, which are commonly called planispheres.

The *Sea ASTROLABE* is an instrument formerly used for taking the sun's altitude at sea; but since the invention of Hadley's Quadrant, they are rare to be met with, that instrument being so much superior. The sea astrolabe consists of a brass circle, about one foot in diameter, and six or seven lines in thickness, that it might be pretty weighty: there was sometimes a weight of six or seven pounds suspended at the point C, (Plate XI. fig. 5.) so that when the astrolabe was hung by the ring A, which was moveable, the instrument would turn any way, and keep a perpendicular situation, notwithstanding the motion of the ship. The limb of this instrument is usually divided into four times 90°, and sometimes into halves, or quarters of degrees. It is absolutely necessary that the right line D, G, B, which represents the horizon, be perfectly level, so that the beginning of the divisions of the limb of the instrument may be graduated therefrom. Now to examine this, observe some distant object through the sights or sights F, E, and fastened near the ends of the index, freely turning about the center G; place your eye to one of the said sights, as F, and look at a distant object through the other sight E; then turning the astrolabe about, letting the index remain at rest, look for the distant object, placing your eye at E; and if you find it through the other sight F, without moving the index, you are certain the fiducial line of the index is right, or truly horizontal. But if at the second time of observation, the index must be raised, or lowered, before the object becomes visible through the two sights; then the middle point between the two positions will shew the true horizontal line passing through the center of the instrument, which must be verified by repeated observations, before the divisions of the limb are begun to be graduated.

The method of making observations with this instrument, is, to hold the astrolabe suspended by the ring, and turn its side toward the sun; then

move the index or label till the sun's rays shine through both the sights on the index, and you have the sun's altitude pointed out on the limb by the extreme points of the index, comprehended between the horizontal radius G D, and the sun's rays F G E *, because the instrument in this situation represents a vertical circle.

The astrolabe by some is now accounted the best instrument for observing the sun's altitude when near the zenith; but we apprehend it is only by such who have not been used to make observations with accuracy; nor can we find by experience where the difficulty lays, so much talked of by navigators, in observing the sun's altitude when in the zenith, with a Hadley's Quadrant; but rather look upon it as the most accurate of any, being almost instantaneous; though the reason, we apprehend, from what we have seen, arises from their observing about once in a minute, and the sun changing its azimuth so very instantaneously, that they have lost it when they look again, and so from their own neglect arises the difficulty.

ASTROLOGICAL, something belonging to astrology.

ASTROLOGY, in the modern acception, implies the pretended art of foretelling future events, by observing the different aspects and situations of the heavens, and from thence to judge of the effects and influences of the stars and planets on human actions.

The word astrology is formed from the Greek *αστρον*, a star, and *λογος*, a discourse; whence in the literal sense, it signifies the doctrine or science of the stars; and was formerly the same with what we now call astronomy. The reason of this change of the word astrology to astronomy, was because of the absurdities that were gradually introduced into that science, by such whose natural inclination led them to impose on the weak and credulous part of mankind; which they found could not be done more effectually and plausibly, than by pretending to foretel future events from their great knowledge of the heavens. Therefore those whose only desire was to seek after truth, thought proper to distinguish themselves by the name of astronomers, from those jugglers of mankind; not being willing to be encouragers and partakers with them in the least shadow or appearance.

In the present age, astrologers, or conjurers, have by our legislature been obliged to keep their knowledge to themselves, not daring publicly to expose it to sale; by which means it is become contemptible for any to declare their belief therein: however, from our own knowledge we are sorry to declare, that the number is incredible who secretly apply at different places to be made acquainted with their future fortune. The motives are chiefly a desire of matrimony, revenge, grandeur, and sometimes

sometimes covetousness. The greatest number conflicts chiefly of those whose motive is matrimony; nor need we wonder, when we consider how strongly the inclinations of youth are directed that way by nature, and how hard it is on the fair sex that they are obliged to fulfil the old proverb, which we apprehend most of our readers are acquainted with. It is very surprizing that many of those are very sensible and discerning in every other particular, and yet suffer themselves in this article to be imposed upon with very little or no trouble, and even become strong advocates for their deceivers, where they are not ashamed to own their connections or enquiries.

Astrology is commonly divided into two branches, natural and judicial.

The former being the production of natural effects, as the changes of weather, winds, hurricanes, storms, earthquakes, floods, thunder, rain, &c. this art properly belongs to physiology, or natural philosophy, and is only to be gathered from accurate and continual observation of the different phenomenas in nature.

The latter is that which pretends to foretell moral events, or such as have a freedom of the will. This art is sometimes called divining; it treats of the revolution of the years of the world, of nativities, of horary questions, good or bad hours, distribution of houses, &c. all ridiculous and stupid.

ASTRONOMICAL, something belonging to astronomy; thus we say, astronomical calendar, characters, column, horizon, hours, month, observation, place, quadrant, ring-dial, sector, tables, telescopes, time, year, &c. See each under its respective article, **CALENDAR, CHARACTER, &c.**

ASTRONOMY, that science which treats of the heavenly bodies, teaching us to observe and discover their true motions, magnitudes, distances, eclipses, oppositions, conjunctions, mutual aspects, &c.

Astronomy, among all the sciences studied by man, may be esteemed the most excellent and most sublime; for there is no other knowledge, acquired by the light of nature, which teaches us truer or juster notions of the Supreme Being than astronomy. Nothing supplies us with more forcible and convincing arguments of the being of a God, than our contemplation on the celestial bodies, and observing their motions. By astronomy we discover the wonderful harmony of nature, where-with the frame and structure of all created beings are linked and knit together, to constitute the great machine of the universe. No science ravishes the mind of man sooner into an admiration and adoration of his Maker; for who can contemplate on so many immense bodies, endued with heavenly light, so beautiful to the eye and amusing to the mind; or who can consider their mutual inter-

courses, regular motions, determined circulations, their revolutions and periods, all settled by a divine law with such admirable harmony, but must cry out with David, *The heavens declare the glory of God, and the firmament sheweth his handy-work*; or with Cicero, who was only guided by the light of reason, "Nothing is more evident, nothing more plain, when we look up to the heavens and contemplate the bodies there, than that there is a Deity of most excellent wisdom who governs them." It is by this science that the very faculties of man are enlarged with the grandeur of the ideas it conveys, his mind exalted above the low contracted prejudices of the groveling vulgar, and his understanding clearly convinced of the existence, wisdom, power, goodness, omniscience, omnipresence, omnipotence, and superintendency of the Supreme Being, over, and in all his works!

The greatest heroes in various ages, as well as kings and emperors, have taken pleasure to study and improve this science: the Chaldean wisemen and philosophers were always revered by their antient kings, who thought it absurd that any should govern the world, who knew not what the world was. There is no science in which there are fewer difficulties to be explained, objections to be answered, or scruples to be removed, than there are in astronomy, or perhaps, that has attained to greater perfection than it has at this present time. The certainty and evidence of its demonstrations is not inferior to geometry; its usefulness is manifold; and the scope of its subject so large, that it comprehends nothing less than the whole universe.

Astronomy is not only useful and pleasing, as it improves the mind, and by its delightful speculations encreases the force and penetration of the understanding, but it is likewise a considerable help to the perfecting of other arts and sciences. In how great darkness would the geographers and the chronologists wander, were they not assisted with light from astronomy? To it we are indebted for our knowledge of the figure and magnitude of the earth, and the method of finding or determining the situations and distances of places. We learn from it the true measure of the year, and can give an account of actions according to the true order of the times in which they happened. It is from astronomy we are certain, that the darkness at the crucifixion of our Saviour, was not any eclipse of the luminaries, but the displeasure of the Almighty, which he pleased to signify by a supernatural cause, and as a miracle to convince all deistical astronomers, as well as others, of the divinity of his beloved Son. Hence it is evident how useful astronomy is to human affairs; for without it we could have no geography nor chronology, and consequently, no certain account of history.

But among all the arts there is none that has received greater improvements from astronomy, than navigation has done. For by our knowledge in it, we can carry our ships through the vast ocean in a right course, though there is no tract to be seen, and visit the utmost regions of the earth. Hence arise the advantages of trade and commerce; so that whatever things other countries afford, that are either precious or delightful, we receive and enjoy without the inconveniencies of intemperate heats or colds, to which those countries are liable. It is owing to our skill in navigation, that our British monarchs have obtained the sovereignty of the seas: so that there is no nation at what distance soever, but what are kept from doing injuries to our countrymen, by the terrors of a British fleet.

By astronomy, in its present perfection, we are enabled to foretell, for many ages to come, the eclipses both of the sun and moon, very minutely; their quantities and durations, the conjunctions, oppositions, and mutual aspects of the planets, and what will be the distances of all the stars from the pole at any time, their places and motions having been exactly settled from constant observation; though at the same time the science of geography, or a description of our own habitation, is so imperfect, that we have an exact determination of the longitudes and latitudes of but a very few places: however, we do not doubt but the honourable commissioners of the board of longitude will shortly take this into consideration, and send out a person properly qualified, with good instruments, to apply the noble science of astronomy as much as possible, where it is so very beneficial to mankind; for being able to determine the longitude of the ship will be of little service, if we are unacquainted with the longitude of the port bound for.

No philosopher has ever yet discovered the figures of the small particles of matter, or the texture, intervals, form, and composition of the parts of the most common plant. Nor has any physician yet found out the reason of the virtues and operations, by which their medicines affect the human body. And even in all animated and vegetable bodies, the fountain and first principle of life and action is unsearchable, and looks like a mystery much beyond the reach of our understanding, which knowledge perhaps in this life is never to be attained. But astronomers in their proper science meet with no such difficulties; they contemplate not the natures, but the motions, of the celestial bodies, and they clearly account for the phenomena, or appearance, that arise from thence; they not only determine what sort of motion the planets have, and in how large a compass they circulate, but they likewise shew us the crooked tracts in the immense regions of space, which the wandering comets take; they can give us the geome-

trical properties of their orbits, and the laws which they observe in describing them. The astronomers are not ignorant where or when the planets are at their farthest distance from the sun, and participate the least of his heat and light; from whence they return, and are constantly quickened in their motions by the sun, who draws them towards himself, till they come to those parts of space where they make their nearest approach to him, enjoy most of his heat and light, and are actuated by the greatest force of their own gravity.

By astronomy we have learned the vast distance of the earth from the sun; and although its circumference is found to be 25,020 miles, yet, if viewed by a spectator placed at the sun, would scarce be visible, or appear no bigger than a point. But what is this distance when compared with that immense space betwixt us and the fixed stars? for though the earth, in its annual revolution, is nearer to some of the stars at one time of the year than at another, about 162 millions of miles, yet their apparent magnitudes, situations, and distances from one another, still remain the same: nor has our most ingenious astronomer, Dr. Bradley, with the most accurate instruments, been able to discover that the nearest stars have any parallaxic angle, though observed at such periods of the earth's orbit, that the two stations of observation are no less distant than 162 millions of miles from each other; and often have we heard this great man declare, that if their parallax had amounted to half a second, he did not doubt but he should have discovered it.

By the assistance of telescopes we discover an innumerable quantity of stars, which are not perceivable with the naked eye, and the better our glass, the more of those telescopic stars become visible; therefore, when we consider these things, we may very naturally conclude, that they are not placed in one concave surface, but scattered at immense distances from one another, through unbounded space.

The sun, from our proximity with it, appears very large, bright, and splendid, in comparison of the stars; but was an observer placed at the same distance from one as the other, no doubt but he would find them put on the same appearance in every circumstance. When we consider the immense distance of the stars from the sun, we must conclude that they shine with their own native and unborrowed light; for the rays of light passing through such an immense space must be scattered and dissipated before they arrive at such remote objects, nor could they be transmitted back to our eyes, so as to render these stars visible by reflection: much more to shine with that lustre and brilliancy that many of them do, especially Sirius, which seems to vie in splendor with some of the planets.

It is no ways probable that the Almighty, who always acts with infinite wisdom, and does nothing in vain, should create so many glorious suns, fit for so many important purposes, and place them at such distances from one another, without proper objects near enough to be benefited by their influences. Whoever imagines they were created only to give a faint glimmering light to the inhabitants of this globe, must have a very superficial knowledge of astronomy; and a mean opinion of the Divine Wisdom; since, by an infinitely less exertion of creative power, the Divinity could have given our earth much more light, by one single additional moon.

Instead then of one sun and one world only in the universe, as the unskilful in astronomy imagine, that science discovers to us such an inconceivable number of suns, systems, and worlds, dispersed through boundless space, that if our sun, with all the planets, moons, and comets belonging to it, were annihilated, they would be no more missed out of the creation than a grain of sand from the sea-shore; the space they possess being comparatively so small, that it would scarce be a sensible blank in the universe; although Saturn, the outermost of our planets, revolves about the sun in an orbit of 4884 millions of miles in circumference, and some of our comets make excursions upwards of ten thousand millions of miles beyond Saturn's orbit; and yet, at that amazing distance, they are incomparably nearer to the sun than to any of the stars, as is evident from their keeping clear of the attractive power of all the stars, and returning periodically by virtue of the sun's attraction.

From what we know of our own system, it may be very reasonably concluded that all the rest are with equal wisdom contrived, situated, and provided with accommodations for rational inhabitants.

To an attentive considerer, it will appear highly probable, that the planets, together with their attendants called satellites or moons, are much of the same nature with our earth, and destined for the like purposes: for they are solid opaque globes, capable of supporting animals and vegetables. Some of them are bigger, some less, and some much about the size of our earth. They all circulate round the sun, as the earth does, in a shorter or longer time, according to their respective distances from him; and have, where it would not be inconvenient, regular returns of summer and winter, spring and autumn. They have warmer and colder climates, as the various productions of our earth require; and in such as afford a possibility of discovering it, we observe a regular motion round their axes, like that of our earth, causing an alternate return of day and night, which is necessary for labour, rest, and vegetation, and that all parts of their surfaces may be exposed to the rays of the sun.

Such of the planets as are farthest from the sun,

and therefore enjoy least of his light, have that deficiency made up by several moons, which constantly accompany and revolve about them, as our moon revolves about the earth. The remotest planet has, over and above, a broad ring encompassing it, which, like a lucid zone in the heavens, reflects the sun's light very copiously on that planet: so that if the remoter planets have the sun's light fainter by day than we, they have an addition made to it morning and evening by one or more of their moons, and a greater quantity of light in the night-time.

On the surface of the moon, because it is nearer us than any other of the celestial bodies are, we discover a nearer resemblance of our earth: for, by the assistance of telescopes, we observe the moon to be full of high mountains, large vallies, and deep cavities. These similarities leave us no room to doubt but that all the planets and moons in the system are designed as commodious habitations for creatures endowed with capacities of knowing and adorning their beneficent Creator.

Since the fixed stars are prodigious spheres of fire, like our sun, and at inconceivable distances from one another, as well as from us, it is reasonable to conclude they are made for the same purposes that the sun is; each to bestow light, heat, and vegetation, on a certain number of inhabited planets, kept by gravitation within the sphere of its activity.

What an august! what an amazing conception, if human imagination can conceive it, does this give of the works of the Creator! Thousands of thousands of suns, multiplied without end, and ranged all around us, at immense distances from each other, attended by ten thousand times ten thousand worlds, all in rapid motion, yet calm; regular, and harmonious, invariably keeping the paths prescribed them; and these worlds peopled with myriads of intelligent beings, formed for endless progression in perfection and felicity!

If so much power, wisdom, goodness, and magnificence, is displayed in the material creation, which is the least considerable part of the universe, how great, how wise, how good, must he be, who made and governs the whole!

It does not seem improbable, or to be in the least doubtful, but that there was some kind of observations of the celestial bodies as soon as there were men, when we consider the beautiful appearance which the heavens constantly present; which is both so glorious and useful, that men could not have eyes to see, and not fix them attentively and considerately thereon.

Among other appearances they could not easily neglect observing the sun change his place of rising and setting; likewise, at certain times of the year, to approach nearer to the earth in his diurnal arch, and at others to mount up to a height much more remote from it; and that his apparent approaching

proaching nearer to the earth made winter, and his removing higher made summer.

Again, so admirably various did the moon appear in her several shapes and dresses of light, that she must naturally engage the eyes of man to frequent speculations, especially when the assumed those various phases or appearances at particular and certain times, which, doubtless, was the cause that every nation measured their times and seasons by observing her constant and periodical circuits; because those periods succeeded much more frequent than the visible elevations and depressions of the sun. To these we may likewise add that beautiful and spangled view of the nightly stars, undergoing likewise their variations, according to the variety of the seasons, and more particularly of the planet Venus, which they must observe to rise sometimes before the sun, and sometimes to set after the sun—Therefore, from such considerations, we may reasonably conclude that celestial observations are as ancient as man, tho' it might be some time before they enquired into the causes of these celestial changes; only accommodating what they first observed to the uses of their lives.

But, because this is too general a method of observation, we shall look back into those times wherein men first began to reduce their celestial observations into method, and founded the art and science of astronomy thereon.

Josephus, the learned antiquarian of the Jews, affirms, "That the sons of Seth invented the science of the heavens before the flood, and engraved the same on two pillars, the one of brick, and the other of stone, so that it might be preserved in one, if by any accident it should be destroyed in the other." But as we find nothing of this in sacred writ, or any other profane history to strengthen this affirmation of Josephus, we cannot therefore think it sufficient to discuss the darkness wherein the origin of astronomy seems involved: nor does the reason this antiquarian gives seem strong enough to evince that astronomy was reduced to a science before the flood; for he supposes the duration of men's lives, in those days, was sufficiently long to perfect the knowledge of astronomy.

Again, the origin of astronomy might be deduced from not long after the flood, if in sacred writ we could find the least word from whence might be argued the truth of what the same author writes; namely, that the Egyptians were taught astronomy by Abraham. It is probable enough that Berofus and others, quoted by Josephus and Eusebius, might have read some such thing among some books of the old rabbins: but that the same should be learned from holy writ, is most improbable, there being no mention made of any such thing. Indeed it is written that Abraham came from Ur of the Chaldeans, but not that he

learned, or received astronomy from them, or that he delivered it from them to the Egyptians; nor will the learned Doctor Saliannus allow it to be even probable that he should instruct the Egyptians in this science, because of his short stay among them. The most ancient monument of the science of the stars that can be found in holy writ is what is said concerning Moses, when he was admitted into the Egyptian court; namely, that he was "learned in all the wisdom of the Egyptians;" and doubtless the wisdom of the Egyptians was contained in the mathematics, and astronomy was always esteemed the best and most sublime part of them.

If we look back into that part of time which is called obscure or fabulous, we possibly may find something relating to our inquiry wrapped up in darksome shrouds of fables.

The most ancient of the heathen gods, we are told by Diodorus Siculus, was Cœlus, so called, because of his high devotion to, and delight in the observation of the stars. This eminent person being the father of many sons, as Atlas, Saturnus, the Titans; and among those especially, Hyperion, and Japetus, from whence we may conjecture, that they being induced by his example, were addicted to the same study: for Cœlus, living near the ocean in Mauritania, extended his kingdom over all Africa, and likewise into a considerable part of Europe, where it is well known, that his son Atlas succeeded him in the same dominions, where he gave his own name to the highest mountain of that country, because he frequently made observations of the motions of the heavens on the top thereof. For the ancients in those days imagined the concave arch of the heavens to be but at a small distance from the top of high mountains; and that the higher they ascended up those hills, the more clear and distinct they could observe celestial objects. To this Diodorus Pliny and others add, that Atlas was feigned to support heaven on his shoulders, because he had framed a sphere or globe, which strongly represented the whole heavenly machine. Clemens Alexandrinus remarks, that Hercules, being both a prophet and philosopher, was reported to come and relieve Atlas, by taking the vast burthen of heaven on his own shoulders; which we apprehend means nothing more than that he succeeded him in the study or science of celestial bodies. Hesperus, the son of Atlas, is reported to have been snatched away by some sudden and violent disease, while observing and speculating the stars on the top of the said mountain; from whence the common people, in respect to his piety and justice, gave his name to the most brilliant and beautiful star, which is also called Vespergo, being the evening-star while seen in the west. As for his sisters, called both Atlantiades and Pleiades, their names were given to that com-
pany

pany of stars which are visible in the back of Taurus; and of one of those was born the famous Mercurius, who is said to have first brought the science of the stars into Egypt; whence, Marcellus, writing of the astronomy of the Egyptians, says of Mercury, *Tu princeps, auctorque sacri Cyllene, tanti, &c.* The Ethiopians contend that they received astronomy from them; for first Diodorus, and afterwards Lucian, has observed the same. Cicero saith of Atlas and Prometheus "That neither had " Atlas been believed to have supported heaven on " his shoulders, nor Prometheus to have been chained " on Caucasus; nor Cepheus, with his wife, son-in- " law, and daughter, been stellified, had not their " divine cognition of celestial bodies first occasion- " ed the perpetuation of their names in the dis- " guise of fables." Saturn, another son of Cælus, who reigned in Italy, Sicily, and Crete, prosecuted his father's studies no less than the former; and it is very probable that he was the first that understood the motion and course of the planet Saturn, which is the slowest of all in its celestial circuits, because he bears that name. Jupiter, his son, applied his mind to the study of the heavens, and for that purpose chose the high mountain Olympus, to make his observations upon, which is the reason that he afterwards is called Olympus, and the name of the mountain transferred into heaven; and Jupiter, because of his great understanding of the order and laws, is said to have the dominion of heaven.

Diodorus saith that Hyperion, who was one of the progeny of Cælus likewise, demonstrated the courses of the sun and moon, and therefore called the sun Helios, after the name of his son; and the moon Selene, after that of his daughter.

Jaetus performed nothing worthy notice in his father Cælus's speculations; but Prometheus whom he begat, who is feigned to have been chained on the hill Caucasus, and to have his heart perpetually torn by a hungry eagle or vulture, made great advances in the science of astronomy. Servius thinks the above fable means nothing more than that with restless care, and solicitude of mind, he constantly execrated himself with observing the stars, and studying their right ascensions and declinations. The same author likewise insists that Prometheus was the first that introduced astronomy and astrology to the Syrians not far from Caucasus. With regard to the fabulous story of his having stolen fire from heaven, for the inanimation of man, means nothing more than that he infused his heavenly knowledge of the stars, and of other celestial motions, into the breasts of men, and inflamed their minds with a desire of studying that noble science. If we examine the fabulous history of Phaeton, we may suppose it hath this mythology; that in his life he had made a considerable progress towards discovering the apparent motion and annual course of the sun, but, dying immaturely, left the theory

thereof imperfect. Likewise that of Bellerophon, who is supposed to have been carried up into heaven by a flying horse, only signifies that he was studious, and had a contemplative mind, eager in the quest of fyderal mysteries. Again, that of Dedalus, who is likewise reported to have been carried into heaven, which arose from his great attention to this science, and his towering speculations; while his less ingenious son Icarus falling much short of his father, both in these sublime observations and in understanding the reasons and demonstrations of his theory, made little progress, in his studies; and fell from the true and epodictical cognition of celestial motions and vicissitudes.

There are likewise many others mentioned by Lucian, as that of Endymion, the favourite of the moon; of Tiresias, the prophet, &c. There is mention made both by Lucian and Tacitus, under the account of herolical times, which seems to come somewhat nearer to the historical, of a remarkable contention that arose betwixt Atreus and Thyestes about supreme dominion; when, by the vote of the Argives, the kingdom was to be given to him who should give the most eminent testimony of science. Thyestes shewed them the sign Aries in heaven, for which he was honoured with a golden ram: but Atreus declared a thing far more excellent; for he made it appear that the apparent motion of the sun and of the starry orb were not carried the same, but quite contrary ways; and consequently, that the part of the heavens which was the west, or occident, of the starry orb, was the very rising, or orient, of the solar orb: therefore Atreus was made king, because of his superior knowledge in astronomy. Lucian reports of Orpheus, that he studied attentively the seven planets, and that he represented their harmony by the seven-stringed harp. Uranus, king of the country situated on the shore of the Atlantic ocean, for his skill in astronomy, is said to have been descended from the gods. Zoroaster, a Persian philosopher, is celebrated by all antiquity, as a skilful astronomer: and the honour and dignity of this science was had in so great a reputation, as to be called the Royal Science, being that in which kings most delighted above all others; for the kings of Africk and Syria first invented and improved it, and that long before it was known in Greece. This Plato acknowledges in his Dialogue which he calls Epinomis. "The first, says he, who observed these " things, was a barbarian, who lived in an ancient " country, where, upon the account of the clearness of the summer-season, they could first discover them, such as Egypt and Syria, where the " stars are clearly seen, there being neither rains " nor clouds to hinder their prospect. And because we are more remote from this summer- " clearness of weather than the barbarians, we " came later to the knowledge of these stars." So Lucian

Lucian tells us, "That the Ethiopians first took notice of the heavenly motions, and, by finding the causes of the lunations, they knew that the moon had no proper light of its own, but borrowed it from the sun." However, it is certain that astronomy, from the very beginning, was cultivated and improved by the eastern nations: for if we may believe Porphyry, when Alexander took Babylon, Calisthenes, at the desire of Aristotle, carried from that city the observations of 1903 years, which brings the beginning of these observations to 115 years after the flood, and 15 years after the building of Babel. Pliny, in his Natural History, relates that Epigenes affirmed, that the Babylonians had observations of 720 years, all graven upon bricks. And Achilles Tatius, in the beginning of his Introduction to Aratus's *Phænomena*, informs us, "That the Egyptians were the first who measured the heavens and the earth; and their science in this matter was engraven on columns, and by that means delivered to posterity." Yet the Chaldeans take the honour of the invention to themselves, and ascribe it to Belus." The Greeks had all their astronomical learning from Egypt: for Laertius owns that Thales, Pythagoras, Eudoxus, and many others went to that country to be instructed in the sideral science: these men were not only the first, but the greatest philosophers that Greece produced: and from the same author we know, that those who staid longest in that country were most famous for their skill in geometry and astronomy, after they returned home: so Pythagoras, who lived in society with the Egyptian priests seven years, and was initiated into their religion, carried home from thence, besides several geometrical inventions, the true system of the universe; and was the first that taught in Greece, that the earth and planets turned round the sun, which was immoveable in the center, and that the diurnal motion of the sun and fixed stars was not real, but apparent, arising from the motion of the earth round its axis. At that time no body was esteemed as a philosopher, but who was well acquainted with the mathematical sciences.

But these sciences were soon neglected by the philosophers that came after them, who much degenerating from their predecessors, had so little care and concern for the mathematical sciences, especially astronomy, that of all the observations of eclipses, for the space of near 2000 years, that were sent from Babylon by Calisthenes, Ptolomy could recover but a very few, the rest being lost by the carelessness, negligence, and want of skill of those men who should have preserved them; for these pretenders to philosophy, having no concern for the useful parts of it, spent their time about trifles, and disputes of no value, and in endeavouring to find out sophisms, whereby they would impose upon their own and the common sense of all

mankind: such were Zeno's arguments against motion, and most of the philosophers disputations against the divisibility of matter *in infinitum*; whereas a little knowledge of geometry would easily have dissolved all the difficulties they could raise. But tho' astronomy was thus banished out of the schools of the common philosophers, yet it was received and cultivated by some, tho' but a few, especially by the Pythagorean sect, which flourished in Italy many years, among whom was Philolaus and Aristarchus Samius. The Ptolemy's, kings of Egypt, were also great patrons of learning; they founded an academy for astronomy at Alexandria, which furnished us with great men, the chief of whom was Hipparchus, who, according to Pliny, "undertook a business which would have been a great work for a god to perform, that is, to number the stars, and leave the heavens for an heritage to all that come after." This man foretold the eclipses of both sun and moon for six hundred years; and upon his observations is founded that precious work of Ptolomy, which he called his *μικράν συντάξιν*, or his Great Construction; for from them he gathered the precession of the equinoxes, and the theory of the planets.

When Egypt was conquered by the Saracens, and Alexandria reduced under their jurisdiction, the conquerors took astronomy, with the rest of the liberal arts, under their protection; and took care that most part of the books concerning the liberal arts and sciences should be translated from the Greek into their own Arabian language.

The Saracens passing from Africa into Spain, and having a commerce with the western European nations, imparted to them the science of astronomy, which before was almost lost in Europe; so that about the year 1230, at the command of the emperor Frederick, Ptolomy's *Almagest*, or his great *Syntaxis*, was translated from the Arabic into Latin.

After that time, astronomy received many improvements from the patronage of the greatest princes, and the labours of the most celebrated philosophers; among whom, in the first place, is to be named Alphonfus king of Castile, who is never to be forgotten, on the account of the astronomical tables called after his name. Nicolaus Copernicus was not only a diligent observer, but also a restorer of the ancient Pythagorean system. Prince William, landgrave of Hesse, who procured quadrants and sextants much larger than what were formerly used, to observe the true places of the stars: this prince's observations are published by Snellius. Sir Henry Savill was most skilful both in astronomy and geometry, who is ever to be honoured for his munificence in founding our two professorships of astronomy and geometry in the university of Oxford, and endowing them with ample salaries: upon which account, and many other be-

nefits he bestowed on the learned world, he will always be had in remembrance with the greatest respect. That noble Dane, Tycho Brache, who for his skill in observing, was superior to all that went before him; and who, for the furniture of his observatory, exceeded even princes and kings. He published a catalogue of seven hundred and seventy fixed stars, which he had diligently observed. John Kepler, a most excellent astronomer, by the help of Tycho's labours, found out the true system of the world, and the laws the celestial bodies observe in their motions, with which he vastly improved astronomy: his excellent works are well known to the learned world, and will ever shew how much he is to be praised. Galileus, the Lyncean philosopher, who first applied a telescope to the heavens, and by its means discovered a great many new surprizing phenomena; as the moons or satellites of Jupiter, and their motions; the various phases of Saturn; the increase and decrease of the light of Venus; the mountainous and uneven surface of the moon; the spots of the sun; and the revolution of the sun about his own axis; all which were first observed by this great philosopher.

Hevelius has given us a catalogue of stars much larger than Tycho's, composed from his own observations. Huygens and Cassini first saw the satellites of Saturn, and discovered his ring. Mr. Flamsteed, who for more than forty years watched the motion of the stars, and has given us innumerable observations of the sun, moon, and planets, which he made with instruments much superior to any that had been made before, whence astronomers could rely on his observations more than those that had been made without the assistance of telescopes. The said Mr. Flamsteed likewise composed the British Catalogue, containing about three thousand stars, which is twice the number that are in the catalogue of Hevelius, to each of which he has annexed its longitude, latitude, right ascension, and distance from the pole, with the variation in right ascension and declination, while the longitude encreases a degree together with most of his observations.

The great and immortal Sir Isaac Newton, who, besides his innumerable other wonderful inventions, has discovered the fountain and spring of all the celestial motions, and the great law which is universally diffused through the whole system of nature, which the almighty and wise Creator has commanded all bodies to observe, viz. That every particle of matter attracts each other in a reciprocal duplicate proportion of its distance.

This law is, as it were, the cement of nature, and the principle of union, by which all things remain in their proper state and order; it detains not only the planets, but the comets, within their due bounds, and hinders them from making excursions into the immense regions of space; which they would do if they were only actuated by a mo-

tion once implanted in them, which naturally they would always preserve, according to the principal law of motion.

We are obliged to the same gentleman for the discovery of the law that regulates all the heavenly motions, sets bounds to the planets orbs, determines their greatest excursions from the sun, and their nearest approaches to him. To this sublime genius we owe, that now we know the cause why such a constant and regular proportion is observed by both primary and secondary planets in their circulations round their central bodies, in comparing their distances with their periods; and why all the celestial motions are still continued in such a wonderful regularity, harmony, and order. The same incomparable person having a complete knowledge of the laws of nature and motion, has from them furnished us with a new theory of the moon, which accurately answers all her inequalities, and accounts for them by the laws of gravity and mechanism; so that now the moon's place, computed by the rules of this new theory, which has been corrected by Dr. Bradley's accurate observations; does not sensibly differ at any time from what it is observed to obtain in the heavens, which far exceeds the hopes and expectations of our astronomers; so that we have now a prospect of improving our navigation, by finding from observations of the moon the longitude of a ship at sea, a problem, the solution of which has long been desired, and is now completed.

Astronomy owes many and great improvements to the indefatigable Dr. Halley, in whose labours there shines out the greatest dexterity in practical astronomy, and a most profound and exquisite skill in geometry: he has favoured the world with the astronomy of comets, astronomical tables, and a catalogue of the southern stars.

The next of the Regius Professors of astronomy is Dr. Bradley, whose superior merit and abilities in practical and theoretical astronomy are well known to the world to excel all that went before, but we hope not all that will follow. 'Tis to this great genius we owe the discovery of the nutation of the earth's axis, the aberration of the stars, &c. discoveries, which in themselves are so minute, that some of our modern pretended practical observers, whose heads and hands are too immechanical for such employment, will never be able to corroborate.

The reverend Nathaniel Bliss, successor to Dr. Bradley, was the next and last of the deceased Regius Professors; but his short enjoyment of the royal place, and bad state of health, prevented him from letting the world know he was not less ingenious than his predecessors.

The writers on astronomy are Albategnius, Sacro Bosco, Regio Montanus, Purbachius, Lanstergius, Longomontanus, Clavius, Boyer, Hook, Horrox, Ricciolus, Sir Jonas Moore, Tacquet, Bullialdus, Ward,

Ward, Count Pagan, Wing, Street, De la Hire, Dr. Gregory, Mercator, Whiston, Keil, the two Cassini's, Leadbetter, Dunthorn, Hodgson, Brent, Dr. Long, De la Caille, Wright, Ferguson, Heath, Kennedy, De la Lande.

Astronomy is sometimes divided into old and new.—The *old* astronomy is that which supposes the earth fixed and quiescent in the center; and that the heavenly bodies perform their revolutions round it.

The *new* astronomy is that which has generally been followed since the time of Copernicus, who revived the Pythagorean, or true solar system. See *COPERNICAN System*.

ASTROSCOPE, the name of an instrument composed of two hemispheres, with the constellations delineated on the superficies.

ASTYNOMI, in antiquity, magistrates at Athens, whose office was the same with that of the ædiles at Rome. See *ÆDILE*.

ASYLUM, a place of refuge, or sanctuary: it is compounded, according to Servius, of *a*, priv. and *συλασι*, to draw out, because no one could be taken away by force out of an asylum.

Asylums are of very ancient date, both amongst the Heathens and the Jews: the first that we read of, among the former, was one established at Athens, by the descendants of Hercules, to shelter themselves from the fury of his enemies. In the days of Moses, asylums were in use; for God commanded him to appoint cities of refuge, to which those who had been guilty of particular crimes might escape, and continue there unpunished and unmolested.

The temples, altars, statues, and tombs of heroes, were of old the ordinary retreat of those who found themselves aggrieved by the rigour of the laws, or oppressed by the violence of tyrants: but of all others, temples were esteemed the most sacred and inviolable refuge. They supposed that the gods took upon them to punish the criminal who thus threw himself upon them, and that it would be the highest degree of impiety, to attempt to wrest vengeance out of the hands of the immortals. Hence arose, amongst the Greeks, a kind of proverbial saying, Εχει γαρ καθούριον, θρησκον πεσσαν, δολοι δε ζωουσ θεον: "A wild beast has for its asylum a rock, or den, and slaves the temples of the gods."

It is reported that there were asylums at Lyons, and Vienne, among the ancient Gauls, from which no one durst attempt to force criminals away: and there are even now some cities in Germany, which preserve the ancient right of asylum. We meet with the inscription ΑΣΤΑΟΙ, to which is added ΙΕΡΑΙ, on the medals of several ancient cities, particularly in Syria: thus for instance, ΤΡΟΤ ΙΕΡΑΣ ΚΑΙ ΑΣΤΑΟΣ ΣΙΔΩΝΟΣ ΙΕΡΑΣ

ΚΑΙ ΑΣΤΑΟΣ. There were formerly in Athens six altars or temples, that enjoyed the right of asylum, viz. the temple of Pity, the temple of Minerva, the temple of the Furies, the temple of Munychia, and the two temples of Theseus, of which one was within the city, and the other without the walls. These temples afforded a refuge or sanctuary to malefactors of all kinds, to slaves who had fled from their masters, and to debtors of every denomination, whatever might be the nature or amount of their debts. No one could be forced from these retreats; but if it was found that any one who had fled thither, was guilty of premeditated villainy, that the number of crimes might not encrease through impunity, he was suffered to starve with hunger, or fire was set to the place, to oblige him to quit it: hence Euripides makes Andromache say to Hermione, *πυρ τοι προσοισι*.

In the times of Constantine and Theodosius, asylums were found in the Christian world, the altars and insides of churches only being places of refuge. Afterwards this privilege was extended to church-yards, the houses of bishops and priests, the graves and sepulchres of the dead; nay, even to crosses, schools, monasteries, and hospitals. At length, these asyla, or sanctuaries, were stripped of their immunities, as they contributed only to make guilt more bold-faced and abandoned.

ASYLUM for penitent Prostitutes, commonly called the MAGDALEN-HOUSE, a charitable foundation, which was carried into execution in the year 1758, and does honour to the benevolent and Christian spirit of the present age. It is intended to rescue the most indigent and helpless part of the creation from variety of wretchedness; to relieve those unfortunate females who have been seduced from their innocence, and prevent them from plunging still deeper and deeper into sin, till disease and death put an end to their miserable beings. As it is impossible to conceive any thing more deplorable than a state of guilt and prostitution, that charity cannot fail of being highly useful which is intended to remedy such terrible evils, and provide for the temporal and eternal good of our fellow-creatures. Such a charity is this, of which we are here speaking; a charity that extends its influence to the most wretched and abandoned; to those who would otherwise be exposed to the nauseous breath of brothel rildry, and the wanton insults of ungoverned riot; who are deserted by their friends, and spurned at by the world; poor houseless wretches, subject to every misery that human nature can experience, to scorn and penury, to disease and pain! From this shocking condition, they are removed by this excellent charity; and instead of continuing the bane of youth, and the pests of society, are converted into useful members of the community, by having an opportunity given them

them of repenting of their crimes, and exercising their talents in some honest and beneficial employment.

This charity is under the direction of a president, four vice-presidents, a treasurer, and committee of twenty-one governors, seven of whom are to be elected yearly. No business is to be transacted except at a general court, which is to consist of at least ten governors, the president, or vice-president, and the treasurer. These general courts are to be held quarterly, viz. on the last Wednesday of March, June, September, and December. A quorum, consisting of five of the general committee, are to sit once a week or oftener, to receive persons petitioning for admittance, inspect the cloathing, furniture, and provisions, examine the conduct of all the officers and servants, &c. A person is qualified to be a governor for life, who shall subscribe twenty guineas, and for one year, who shall subscribe only five. The *Penitents* are distributed into separate wards, over each of which a head is appointed, yet they are all subject to the *Matron*. They are entirely concealed from sight, except when they attend divine worship in the chapel; and can receive no messages, but what are beforehand communicated to the matron. Upon their being guilty any of them of bad behaviour, they are either confined for a time, reprimanded, or dismissed from the society, without a possibility of being admitted again, according to the nature of their crime. Each person is employed in such work and business, as is suited to her ability; and part of the benefit arising from her labour and ingenuity, is allotted to her. The articles in which they are employed, are making their own cloaths, which consist of a light grey uniform; knitting, and spinning; making bone lace, black lace, artificial flowers, and children's toys; winding silk, drawing patterns, making women and childrens shoes, mantuas, stays, coats, &c. After the continuance of any woman in the house for three years, upon her modest and virtuous demeanor, or upon the application of her parents or friends, the governors may discharge her by her own consent; and upon her discharge, the cloaths which she brought along with her into the house, or if they have been sold, their value in money will be returned to her, together with a certificate of her good behaviour. If any woman is placed in a service out of the house, and shall continue one whole year in such service, to the entire approbation of her master and mistress, a gratuity not exceeding two guineas, will be given her by the committee. Upon the good behaviour of the women, the committee will always interest themselves to obtain a reconciliation with their parents and friends, when their contract is cancelled. In short, this scheme seems to be excel-

lently calculated to preserve the lives, the welfare, and the souls of many unfortunate women; to recover those that are lost, and bring them back as well to the community, as to the fold and family of Christ's flock; and as such, cannot fail of meeting with the best wishes and assistance of every true lover of his country, his religion, and his God.

ASYMMETRY, the want of proportion between the parts of any thing; being the opposite to symmetry.

The word is Greek, and compounded of *as*, priv. *συρ*, and *μετρον*, measure.

It is sometimes used by mathematicians to signify incomprehensibility, or when there is no common measure between two quantities or magnitudes.

ASYMPTOTE, in geometry, a line which continually approaches nearer to another, but tho' continued infinitely will never meet with it.

Definition of the ASYMPTOTES. If the right line *aTA* be drawn perpendicular to the axis *IT*, at one of its extremities, as *T*, and *TAq* be made equal to the rectangle *IDT*; having taken *Ta* = *TA*; through the centre *C* and the points *A*, *a* draw the lines *AC*, *aC*, indetermined both ways from the centre; these lines are called asymptotes to the hyperbola, or the opposite hyperbola's.

COROLLARY.

It is evident that the asymptotes to one hyperbola are also asymptotes to the other that is opposite.

PROP. I.

If the ordinate of an hyperbola be produced until it meet the asymptotes in *B* and *G*; the rectangle *GPB* is equal to *TAq*. (See Plate XI. fig. 6.)

The lines *TA* and *OB* are parallel; wherefore *CTq*: *TAq* :: *COq*: *OBq*, and *CTq*: *TAq* :: *COq* - *CTq* = rectangle *IOT*: *OPq*. and, *ex æquo*, *COq*, *OBq* :: *COq* - *CTq* :: *OPq*, and alternately *COq*: *COq* - *CTq* :: *Oq*: *OPq*, and, by division, *COq*: *COq* - *COq* + *CTq* = *CTq* :: *OBq*: *OBq* - *OPq*, and alternately *COq*: *OBq* :: *CTq*: *OBq* - *OPq* = rectangle *GPB*: but in the first proposition *COq*: *OBq* :: *CTq*: *TAq*; wherefore the rectangle *GPB* = *TAq*. *W.W.D.*

PROP. II.

If from some point, as *P*, in a hyperbola be drawn the right line *Pg* parallel to the axis *IT*, meeting the two asymptotes in *b* and *g*; then is the rectangle *gPb* equal to *CTq*.

From the position of the asymptotes, is bisected in *O* by the axis *CM*; and from similar triangles, *OBq*:

OBq: (See fig. 6.) $COq = POq$; COq , or OPq : obq ; and by division, OBq : $OBq - OPq$:: OPq : obq ; and alternately, and by inversion, $OBq - OPq = \text{rectangle } GPB$: OPq :: $obq = \text{rectangle } gpb$: OBq . $OPq = COq$; but OBq : COq :: TAq : CTq ; wherefore, *ex æquo*, $\text{rectangle } GPB$. $\text{rectangle } gpb$: TAq . CTq ; but $\text{rectangle } GPB = TAq$. (by the last prop.) wherefore $\text{rectangle } gpb = CTq$. *W.W.D.*

P R O P . III.

The hyperbola and its asymptote approach continually to one another the farther both of them are produced, and yet will never meet, though PB, the part of the ordinate contained between the hyperbola and its asymptote, may be found such, that it shall be less than any line given.

The rectangle GPB is equal to TAq . (See Plate XI. fig. 6.) (by prop. I.) but GB encreases the farther it is distant from C; wherefore PB continually diminisheth; but it can never become equal to nothing, for then the rectangle GPB would be equal to nothing, which would contradict the forementioned Prop. wherefore the hyperbola and its asymptote can never meet: then if a rectangle be made, one of whose sides shall be less than the given line, which rectangle shall be equal to TAq ; the sum of the two sides of this rectangle, as GB, being applied within the angle made by the asymptotes perpendicularly to the axis IT, P the point that divides the sides of that rectangle will be within the hyperbola (by prop. I.) and consequently PB is less than the given line. *W.W.D.*

P R O P . IV.

If two points, as P and A, (Plate XI. fig. 7.) be taken in a hyperbola, or one point only in each of the opposite hyperbola's, and through these points be drawn two right and parallel lines, as PH and AD terminated by one of the asymptotes, as CD; in like manner, if through the same points P, A be drawn two other lines PF, AB, parallel to one another, and terminated at the other asymptote CB; then is the rectangle $PH \times PF = AD \times AB$.

Through the points P, and A, having drawn the perpendiculars to the axis EPG, and LAK terminated by the asymptotes in EG, LK; the triangles EPF and LAB, PGH and KHD, are similar, by reason the lines that compose them are parallel; wherefore EP . PF :: LA . AB , and PG . PH :: AK . AD ; wherefore multiplying these two proportions into one another, antecedents into antecedents, and consequents into consequents; there will arise this proportion; $EP \times PG$: $PF \times PH$:: $LA \times AK$: $AB \times AD$; but the rectangle EPG equal rectangle LAK; for

(by prop. I.) they are equal squares of one and the same right line; wherefore the rectangle $PF \times PH$ is equal to the rectangle $AB \times AD$. *W.W.D.*

C O R O L L A R Y .

It is evident that what we have demonstrated above for two points only, may be demonstrated in like manner for any number of points whatsoever.

P R O P . V.

If a right line, as FH, (Plate XI. fig. 10.) touch an hyperbola in P; then it meets the asymptotes in F and H, and is bisected by the point of contact P.

1. Through the point P draw EPO an ordinate to the axis, and if the tangent P do not meet the asymptotes, it will be parallel to one of them, which let be CG, if it be possible. By prop. III. one may find a line less than PG, which being parallel to CG, let it be comprehended between the hyperbola and the asymptote; this line produced will necessarily meet the tangent FPH parallel to CG within the hyperbola; which is absurd; for FPH is supposed to be a tangent; therefore a tangent meets both the asymptotes, which is the first part of the proposition.

2. If PH be unequal to PF, let it be greater if possible; having cut off $Hp = FP$, draw epg parallel to EPG; then, because $pF = Hp$, and ge parallel to GE, pg : PG :: Hp : HP ; and Hp : HP , or their equals Fp : Fp :: PE : pe , and, *ex æquo*, pg : PG :: PE : pe ; wherefore $PG \times PE = pg \times pe$; and by the converse of the 9th Prop. the point p will be one of the points of the hyperbola; therefore FPH will meet the hyperbola in two points P, p , contrary to the hypothesis, for it is supposed to be a tangent. Wherefore the Proposition is true.

P R O P . VI.

Through the points P, A of an hyperbola, (Plate XI. fig. 9.) draw the right lines FH, BD parallel to one another, and meeting the asymptotes each of them in the points F, H, B, D; then the rectangle $PF \times PH$ is equal to the rectangle $AB \times AD$ or ABq , if BD touch the hyperbola in the point A.

This proposition is evident from prop. IV. and V. for the lines PF, PH, and AB, AD are parallel; and if BD be a tangent in the point A, it is divided by the point A into two equal parts (by prop. V.)

ASYMPTOTIC, something relating to asymptotes. See ASYMPTOTES.

ASYMPTOTIC Space, the same with hyperbolic space.

ASYNDETON, a figure in grammar, implying the want of conjunctions in a sentence. It is compounded of the Greek α , priv. and $\sigma\upsilon\lambda\lambda\epsilon\sigma\iota\varsigma$, I

bind together: because a sentence is connected by the use of conjunctions.

In the following sentence, *Veni, vidi, vici*, the copulative *et* is omitted: as also in that passionate expression of Cicero about Catiline, *Abiit, excessit, evasit, eripit*. This figure is properly applied to express any violent action or emotion of the soul: thus for instance in Virgil,

Ferte citi flammæ, date vela, impellite remos.

When we speak with coolness and deliberation, conjunctions are absolutely necessary; and when we would particularize several things, instead of an asyndeton, we should employ a polysyndeton, or figure by which the copulatives are multiplied. See POLYSYNDETON.

ATARAXY, a term used by the stoics and sceptics to denote that calmness of mind which secures us from all emotions arising from vanity or self-conceit. In this consisted the summum bonum, or sovereign good.

The word is Greek, *αταραξια*, and compounded of *α*, priv. and *ταραξω*, perturbation.

ATAXY, in a general sense, the want of order: with physicians it signifies the irregularity of the crises and paroxysms of fevers.

The word is Greek, *αταξια*, and compounded of *α*, priv. and *ταξις*, order.

ATCHE, in commerce, a small silver coin used in Turkey, and worth only one-third of the English penny.

ATCIEVEMENT, in heraldry, denotes the arms of a person, or family, together with all the exterior ornaments of the shield, as helmet, mantle, crest, scrolls, and motto, together with such quarterings as may have been acquired by alliances, all marshalled in order.

ATE, in the pagan theology, the goddess of mischief.

She was the daughter of Jupiter, and cast down from heaven at the birth of Hercules: for Juno having deceived Jupiter, in causing Euristheus to be born before Hercules, Jupiter expressed his resentment on Ate, as the author of that mischief, and threw her headlong from heaven to earth, swearing she should never return thither again.

The name of this goddess comes from *αταω*, *noceo*, to hurt. Her being the daughter of Jupiter means, that no evil happens to us, but by the permission of Providence; and her banishment to earth denotes the terrible effects of divine justice among men.

ATELLANÆ, in Roman antiquity, comic and satyric pieces presented on the theatre; but as in the later times they grew excessively lewd, they were suppressed by order of the senate.

ATEMPO GIUSTO, in music, signifies to sing or play in an equal, true, and just time.

ATHAMADULET, the prime minister of the

Persian empire, as the grand vizier is of the Turkish empire.

The athamadulet is great chancellor of the kingdom, president of the council, superintendent of the finances, and is charged with all foreign affairs.

ATHANASIAN CREED, that supposed to be composed by Athanasius. See CREED.

ATHANATI, in Persian antiquity, a body of cavalry, consisting of ten thousand men, always complete. They were called athanati, because when one of them happened to die, another was immediately appointed to succeed him.

ATHANOR, in chemistry, a kind of fixed and large digesting furnace, made with a tower, so contrived as to keep a constant moderate heat for a considerable time, which may be increased or diminished at pleasure, by shutting the registers.

Plate XIII. fig. 3. represents an athanor furnace, *aaaa*, the tower of the athanor, or chief furnace, which receives the fuel of the fire: the pricked lines indicate the thickness of the wall: *bbbb*, the inner sides which form the cavity, and are each ten inches long; *c*, the door of the ash-hole; *e*, the upper-door; *d*, the grate which is placed even with the bottom of the door; *f*, the cover where-with the upper aperture of the tower is shut; *gg*, a flue, through which the fire ascends from the tower into the first furnace; *hhhh*, a hollow prism, which forms the first secondary furnace; *ii*, a semi-cylindrical arch, wherewith the aforesaid prism is closed up; *kkkk*, an iron plate coated within, wherewith the first secondary furnace is shut. In this plate is a round hole, through which the neck of the vessel *7* may be passed; *n*, iron-bars; *oooo*, iron-hooks, fastened to the wall to receive the iron-bars; *qqqq*, the funnel of the furnace; *z*, an iron plate, wherewith the funnel may be shut; *tt*, another flue, through which the fire passes from the first secondary furnace to the second; *uuuu*, another secondary furnace cylindrical; *vv*, its upper circular aperture, sloped at the fore-part, to receive an iron pot, which is to be hung in this secondary furnace; *x*, a flue, which conveys the fire from the second to the third furnace; *1111*, the third secondary furnace, having an iron pot, like the second; *2222*, the second funnel; *3*, a plate to shut the funnel; *4*, an aperture which leads from the third furnace into the funnel; *555*, the third funnel; *7*, an earthen retort, placed in the first secondary furnace, with its neck through the hole in the door; *8*, a receiver; *9*, a glass retort, placed in the iron pot belonging to the second secondary furnace, which pot is filled with sand; *10*, a receiver; *11*, a glass cucurbit, with its head placed in the pot of the third furnace; *12*, *12*, stands which support the receivers, and which may be raised or lowered by the help of screws.

Uses of the ATHANOR.—You must put in, at the

the upper arch-door *e*, a semi-cylindrical muffle, twelve inches long, of the same height and breadth of the door, three quarters of an inch thick, and open behind, being *shut* there by the hinder part of the athanor: for this purpose, a tile must be placed on the grate *d*, to support the muffle. Under this muffle you may place your cement-pots, or such bodies as must be calcined with a long and violent fire; which may be done without a muffle, though not so well. In the first secondary furnace, *h h h h*, *ii*, you may perform the most violent distillations with an open fire; for retorts and other vessels may be introduced into it, by taking away the door *k k k*, and placed either upon the hearth itself, or on a particular support of stone: but you must be careful to place those vessels in such a manner, that their necks may pass through the hole in the door *k k*. You may close all the crevices of the door with lute. To the neck of the retort apply a cylindrical segment ten or twelve inches long, that the heat of the vapours may be gradually diminished, lest the receiver, which must be of glass, should split. The receiver must be luted to the other orifice of the said segment, and supported by a kind of triivet. In this chamber, instead of distillations, you may make cementations, calcinations, &c. in which case the round hole in the iron plate *k k*, must be shut.

The second and third secondary furnaces serve chiefly to perform such operations as are made in baths of sand, ashes, or filings. You may also make in these furnaces distillations by a reverberating fire, as in the first; only the fire is less violent in these, though sufficient for distilling aqua-fortis. In order to this, you must take out the iron pot, and invert it on the mouth of the furnace; by this means the segment cut out from the pot, together with that cut out from the side of the cavity, will form a hole for the neck of the retort.

All the apparatus being thus prepared, you must introduce, through the top of the tower *h h h h*, a few burning coals, and then a sufficient quantity of fuel, so that the tower may be entirely filled, or only in part, according to the nature of the operation. Then immediately put on the iron cover *f*, and close exactly all the crevices with lute; for if you neglect this caution, all the fuel contained in the tower would immediately be kindled, which might be attended with very bad consequences.

Manner of regulating the Fire.—The fire may be made very strong in the first chamber *h h h h*, *ii*, by leaving the door of the ash-hole *c*, and the funnel *q q q q*, of the chamber, quite open, and the fire have free liberty to pass from the tower into this cavity: but the closer the funnel is shut, together with the door of the ash-hole, the more the violence of the heat diminishes; and this will be soon effect-

ed, if the iron slider, which separates this cavity from the tower, be partly let down. Observe also, when the strongest fire is required, that the hole in the door *k k* be closely stopped; because, when open, the air, by rushing violently through it, cools the bodies placed in that cavity. At the same time, distillation, or some other process, may be performed, and with the same fire, in the second and third furnaces; for the fire penetrates from the first cavity into the second, and increases when the funnel *2222*, erected on it, is opened: but, before you do this, the funnel of the first cavity must be shut as much as that of the second is opened. By the same means you may hinder the fire, which serves for the operations made in the two first cavities, from going out through their funnels, and force it out through the funnel *555*, by which means it will also act upon the bodies placed in that cavity: for the more the funnel erected on the third cavity is open, the more one or both the funnels of the other cavities must be closed: whence it is plain, that you cannot have the strongest fire in the third cavity, unless there be an equal degree of fire in the other two; but, on the contrary, the heat in the third cavity may be rendered less, by closing its funnel, though it be violent in the others. The same is true of the second cavity, with regard to the first. You cannot make the strongest fire under the muffle placed within the upper door *e*, of the tower, unless you have an equal fire in the first cavity; which fire may consequently be increased by shutting the door quite against the muffle, and diminished by opening it; there being, at the same time, an equal heat in the first and following chambers.

ATHEIST, one who disbelieves the being and providence of God. It is derived from the Greek *α priv.* and *θεος*, a God.

We may distinguish our modern atheists into two kinds; *speculative atheists*, or those who, thro' a pride or singularity of learning, affect to deny the existence of a God, from theory or principle, as they would make us believe; and *practical atheists*, or those whose wicked lives lead them to believe, I mean, to wish that there may be no God. It is to be doubted whether there ever yet existed one sensible reasoning person who actually, and in his heart, entertained a disbelief of a Providence: it is to be doubted, I say, and for this reason; because the whole creation, rational and irrational, animate and inanimate, bear testimony to the great and important truth. That *fools have said in their hearts there is no God*, is not altogether so improbable; as they are incapable of examining any thing with attention, or employing those faculties properly with which nature has invested them. The eyes of their mind are darkened, so that they cannot see the clearest and most glaring truths; and they

they pass their time in a dull inactivity of reason and soul, that degrades and debases them below the brutes.

ATHELING, ADELING, EDLING, ETHLING, or ETHELING, among our ancestors, was a title of honour belonging to the heir apparent, or presumptive, to the crown. This honourable appellation was first conferred by Edward the Confessor on Edgar, to whom he was great uncle, when, being without any issue of his own, he intended to make him his heir.

ATHENÆA, in antiquity, a feast celebrated by the ancient Greeks in honour of Minerva, who was called Athene.

ATHENÆUM, in antiquity, was a public structure wherein the professors of the liberal arts held their assemblies, the rhetoricians declaimed, and the poets rehearsed their performances.

These structures, of which there were several at Athens, were built in the form of amphitheatres, encompassed with seats, called cunei.

ATHEROMA, in surgery, a tumour without pain or discoloration of the skin, containing, in a membranous bag, matter resembling pap, intermixed with hard and stony particles. These tumours are easily cured by incision.

The word is Greek, *αθηρωμα*, and derived from *αθηρα*, pulp, or pap.

ATHLETÆ, in antiquity, persons of strength and agility, properly disciplined for performing in the public games.

The word is Greek, *αθληται*, and derived from *αθλα*, combat.

Under the name athlete were comprehended wrestlers, boxers, runners, leapers, throwers of the discus, and those practised in other exercises exhibited at the Olympic, Pythian, and other solemn games, where prizes were established for the conquerors.

ATHWART, in the marine, across; as, We discovered a fleet at day-break standing athwart us, i. e. discovered a fleet steering across the line of our course.

ATHWART haufe. When a ship is driven by the wind or tide against the fore-part of another, and presses upon it with her side, she is then said to lie athwart-haufe of the latter.

ATHWART the fore-foot : a shot is commonly fired immediately before a ship's fore-part by another of superior force, when she wants to intercept her, that she may remain with her sails slackened until she is examined; and this is called firing athwart the fore-foot.

ATHWART Ships, reaching across the ship, or from one side to the other.

ATLANTIDES, in astronomy, the same with Pleiades. See **PLEIADES**.

ATLAS, in anatomy, the name of the first ver-

tebræ of the neck, or that which supports the head. It has its name from an allusion to a celebrated mountain in Africa, of so stupendous a height, that it seems to support the heavens; and from the fable, in which Atlas, king of that country, is said to bear the heavens upon his shoulders.

ATLAS, in architecture, is a name given to those whole or half figures of men, sometimes used instead of columns or pilasters to support any member in architecture. They are sometimes called Telamones.

ATLAS, in matters of literature, denotes a book of universal geography, containing maps of all the known world.

ATMOSPHERE is a thin elastic fluid, intermixt with particles of different natures surrounding our globe to the height of about forty or forty-five miles. The nature and properties of this fluid, we have shewn under the article AIR. But some of its uses we shall now point out, and first as to Vegetation, Dr. Grew and Malpighi have shewn that it is a principal concurrent therein, and by experiments on seeds sown in earth and put in an exhausted receiver, it has been proved that no vegetation can succeed without it; what makes it so necessary seems to be, because it being more easily rarefied, and heated by the action of the sun than other more compact, heavy, and less springy fluids, is fitter to promote the ascent of juices in the slender channels of vegetables; and there being no fluid without a considerable portion thereof, lodged up and down among its parts, the first impulse of the juices upwards does thence arise. As also because of its active, springy, and subtle nature, it rarefies, actuates, and rehnes the more slyz vegetable juices to promote their circulation, and performs functions on them analogous to that it does on the animal fluids. Next, as to animals, it is well known that they could live but a few minutes without this elastic fluid, and probably that which so suddenly kills thunder-struck animals, is the quick and violent rarefaction of the air about them; for the lungs of all such, upon opening, are found quite destitute of air, and the sides of their vessels quite clapped together. It is certain that the blood is sent from the right ventricle of the heart to the lungs, and if the vessels thereof be not distended or blown up by the air, the circulation must stop there, and the animal perish; and both for the comminution of the particles of the blood, that they may more easily pass through the capillary and terminating vessels, and for the propagation thereof in the wider ones, there is necessarily required a fluid of a determinate gravity and elasticity. We have as great difficulty in breathing, in a thin (as is evident from the difficulty of breathing on the tops of high mountains, and from experiments on animals in nearly exhausted

exhausted receivers) as in a thick air; and even in fishes, where the water in some measure supplies the want of air, yet if you draw out all the bubbles of air which are always found in water, they will languish and die; and in great frosts, if the ice be not broken to admit fresh air, the fish in lochs and ponds will languish and die, not to mention here their swimming-bladders, which are so necessary to them, and communicates with the air in their gills. So that even to them, a certain portion of this elastic fluid is necessary. Now how well is this fluid fitted for the generality of the inhabitants of this globe? it being neither too heavy, nor too light, neither too much, nor too little elastic, for the uses of respiration. Another advantage we reap by our atmosphere, is, that by it our clouds and vapours are supported, without which we should neither have fresh water, nor snow, nor rain, nor any of those things which moisten and enrich our soil, and make it fit for vegetation. For though it be the sun that rarefies the water, and makes it take its first flight in vapours and steams; yet it is by the atmosphere, its progress is continued to the upper regions, and supported when it is there, to be afterwards formed into snow, or hail, or rain, or carried into other regions, whose soil may want it more. Every body knows, that if there were no atmosphere, but a perfect void, around the earth, the action of the sun would not be able to raise the vapours above a few feet from its surface; and that it is only the atmosphere's being specifically heavier than these vapours, that buoys them up in the air, by its greater tendency toward the center. Now then, if there were no atmosphere, the vapours could rise to no sufficient height, and so could never be cooled sufficiently, so as to be formed into snow, or rain; for at a small distance from the earth's surface, the reflected rays of the sun make the places so warm, that no vapour could be turned into snow, or rain, there; for it is the coldness of the upper regions, (being destitute of these reflected rays) and the length of their descent, that forms these clouds and vapours into snow and rain. Whenever the supporting atmosphere becomes lighter than these accumulated vapours, they fall down with the temper of heat or cold they had in the upper regions, and so become snow or rain accordingly. So that it is plain, it is our atmosphere that is one of the principal means of our dews and rains, and all the blessings that follow upon these. A third advantage of our atmosphere is, our breezes and our winds, which carry our ships upon the sea, and purify our air from noxious steams, which (with the concurrence of the sun) melt our snows, and dry our ground when over-moistened; and serve for so many other purposes, for the accommodation of human life. Wind is nothing but a violent motion of the air, produced principally

by its rarefaction, more in one place than another, by the sun's beams, the attractions of the moon, and the combinations of the earth's motions. Without our atmosphere, we should have no more wind above than under ground, and so be deprived of all the benefits arising thence. Lastly, Our atmosphere is the vehicle and medium of sound, that sense which mostly distinguishes us from fishes, and the inferior sort of insects. Sound is nothing but a modulation or percussion of the air, communicated by an impulse from the vibrating sonorous body, and propagated in undulations, through the fluid of the atmosphere, every way round. Without our air we should not be able to hear the report of a thousand pieces of ordnance discharged at the smallest distance, as is evident from the experiments on sounds in exhausted receivers. We should have no such thing as languages or music, and what a comfortable state this would be, we leave the reader to judge. Add to all these, that it is to our atmosphere the beauty, variety of colours and figures, which are painted on the skies, the lightness of our air, and the twilight are owing. By it the day is protracted, and the night shortened, and in these places most, which want those most. By the refractions of our atmosphere, the sun rises sooner, and sets later in appearance, and with its beneficial consequences, even a month sooner in some places than it would otherwise; and the land and mountains appear sooner to the weary wandering sailor. These are great and noble advantages to the inhabitants of this globe, as they best can tell, who by accidents are sometimes deprived of them. From all which, it is very plain that there was counsel and design in the contrivance and production of our atmosphere.

Weight of the ATMOSPHERE upon every square inch on the surface of the earth, is about fifteen pounds, being equal to a column of mercury whose height is thirty inches, and its base one square inch; for such a column of mercury would weigh about fifteen pounds. The weight of the atmosphere therefore which presses upon a man's body, is equal to so many times fifteen pounds, as the surface of his body contains square inches. The reason why a person suffers no inconvenience from so great a pressure, is owing to the air included within the pores and fluids of the body, which by re-action proves a counterpoise to the pressure of the external air.

ATMOSPHERE of the Moon and Sun. See *Moon and Sun*.

ATOM, in philosophy, an indivisible particle, or corpuscle of matter.

The word is Greek, *ατομῶν*, and compounded of *α*, priv. and *τεμνω*, to cut, or divide.

Atoms are properly the *minima naturæ*, the least or ultimate particles into which bodies are divisible; and are conceived to be the first rudiments, or com-

ponent parts of all physical magnitude; or the pre-existent and incorruptible matter whereof bodies are formed.

The notion of atoms arises from a supposition, that matter is not divisible *ad infinitum*. And hence the Peripatetics are led to deny the reality of atoms. An atom, say they, either has parts, or it has not: if it has no parts, it is a mere mathematical point; if it has, these parts must also consist of others, and so on to infinity.

But this is to recede from the genuine characters of atoms, which are not esteemed indivisible from their want of parts (for all physical magnitude must have three dimensions, length, breadth, and thickness, and all extension is divisible); but they are indivisible on account of their solidity, hardness, and impenetrability, which preclude all division, and leave no vacancy for the admission of any foreign force to separate or disunite them.

It is necessary that atoms, as being the first matter, should be indissoluble, in order to their being incorruptible. Sir Isaac Newton adds, that immutability is also requisite, in order to the world's continuing in the same state, and bodies being of the same nature now as formerly.

Hence the ancients were also led to maintain that atoms were eternal; for what is immutable must be eternal.

ATOMICAL Philosophy, the doctrine of atoms; or the method of accounting for the origin and formation of things from the supposition of atoms being endued with gravity and motion. See **CORRUSCULAR Philosophy**.

ATONY, in physic, a relaxation, or debility of the solids of the human body.

The word is Greek, *ατονία*, and compounded of *α*, priv., and *τονος*, tone.

The Methodic sect considered relaxation and stricture, or a mixture of these, as the causes of all distempers.

ATRA BILIS, black bile, among the ancient physicians, implied one of the humours of the body; the moderns call it melancholy. See **MELANCHOLY**.

ATRACTYLIS, distaff thistle, in botany, a genus of plants bearing radiated flowers, containing many hermaphrodite florets, which are included in a common scaly empalement; the seeds are compressed, coronated with a plumose down, and standing on a plane villose receptacle.

ATRACTYLIS is also the name by which Vailant calls a species of the carthamus. See the article **CARTHAMUS**.

ATRAGENE, in botany, a genus of polyandrious plants, the flower of which consists of twelve petals, containing a number of short filaments with oblong antheræ; it hath several oblong germina, which produce a number of caudated seeds.

ATRAPHAXIS, in botany, a genus of hexandrious plants, the flower of which consists of two roundish, sinuated, and permanent petals; it hath six capillary filaments, with roundish anthers, and the calyx, which is permanent, contains a compressed feed.

One of the species of atraphaxis is called atriplex by Tournefort. This is a shrub which rises about four or five feet high, sending out many weak lateral branches, which are armed with spines; these are furnished with small lanceolated leaves of an ash-colour, and are smooth; the flowers come out of the ends of the shoots in clusters, which consist of two white leaves, tinged with purple, and are included in a two leaved empalement, of a white herbaceous colour; they appear in August. This plant is propagated by cuttings, and must be protected from hard frosts.

A-TRIP, in the marine, a ship's top-fails are said to be a-trip, when they are drawn up to the mast-head, or to their full extent. See **TOP-SAIL**.

A-TRIP, the anchor is so called, when the ship, in a perpendicular direction, drags or heaves it off the ground.

ATRIplex, orach, in botany, a genus of polygamious plants, whose flowers are female and hermaphrodite, with no petals; the female flowers have a two leaved empalement, which are plane, large, upright, and pointed in the center: it has a compressed germen, supporting a bipartite style, crowned with a sharp reflexed stigma. The hermaphrodite flowers have a pentaphyllous calyx, which is persistent, and contains five subulated filaments, placed opposite the leaves of the empalement, supporting a double roundish antheræ: the germen is orbiculated, and contains a style like the female, and in both becomes an orbicular compressed seed inclosed in the empalement.

Atriplex is esteemed cooling and emollient, and its seeds, given internally, diuretic, and good in disorders of the uterus.

ATROPA, deadly night-shade, in botany, a genus of pentandrious plants. The common sort, which grows wild in several parts of England, hath a perennial root, which is long, thick, and brown, and sends forth strong herbaceous stalks, which rise to the height of about three or four feet, purple at the bottom, and of a pale-green upwards; thick, hairy, and divided into a few branches: the leaves are numerous, oblong, hairy, of a faint green, and placed irregularly on the branches; the flowers rise from the bosoms of the upper leaves, and are large and campanulated, spreading at the top, which is cut into five segments, of a dusky greenish colour, striated and stained in various degrees with a dull purple; the base within is yellowish, and the upper part purple; from the base of the petal ariseth five subulated filaments, which are topped with large antheræ, which stand upwards; the style is slender,

slender, and a little bent; it rises from a roundish rudiment of a berry, crowned with an oblong stigma, placed transversely; the flowers are succeeded by a large round berry, a little flattened at top, which is first green, but when ripe turns to a shining black, fitting close upon the empalement, and containing three cells filled with kidney-shaped seeds.

This plant is rarely admitted into gardens, nor indeed should it be suffered to grow in any places where children resort, for it is a strong poison, and there have been many instances of its deadly quality, by several children being killed by eating the berries, which are of a fine black colour, about the size of a black cherry, and not unpleasant to the taste. Buchanan, in his History of Scotland, gives an account of the destruction of the army of Sweno the Dane, when he invaded Scotland, by mixing a quantity of the juice of these berries with the drink, which the Scots by their truce were to supply them with; which so intoxicated the Danes, that the Scots fell upon them in their sleep, and killed the greatest part of them; so that there were scarcely men enough left to carry off their king. With these bad qualities it possesses also great virtues, which were known among the ancients, though at present little noticed. Mathiolus mentions the use of deadly nightshade internally, in the distilled water, against inflammations of the viscera, and in a syrup from the juice of the berries; as also outwardly, in various inflammatory swellings. In the writings of those who first described this plant, it is strongly recommended as a cure for cancers, though this article has been long over-looked, as it was dreaded as a poison, while neglected as a remedy: but later experience has proved, that it hath not the desired effect.

ATROPHY, in physic, implies an universal consumption, proceeding from the whole habit of body, and not from any distemper of the entrails; it is attended with no remarkable fever, and is natural in old age.

The word is Greek, *ατροφία*, and compounded of *α*, priv. and *τροφή*, to nourish.

An atrophy is either nervous, or the effect of immoderate evacuations. A nervous atrophy is that which owes its origin to a bad and morbid state of the spirits, or to a weakness or destruction of the tone of the nerves; whence a weakness and an universal consumption of the body proceeds, for want of a proper assimilation of the nutritious juices; so that, from the beginning of the disease, there is a defect of appetite, and a bad digestion in the stomach.

An atrophy from inanition proceeds from a preternatural defect or subtraction of the nutritious juice, which varies according to the different out-

lets of the body, whether by nature or art. See CONSUMPTION.

ATTACHMENT, in law, implies the taking or apprehending a person, by virtue of a writ or precept.

It is distinguished from an arrest, by proceeding out of a higher court by precept or writ; whereas the latter proceeds out of an inferior court by precept only. An arrest lies only on the body of a man; whereas an attachment lies often on the goods only, and sometimes on the body and goods.

An attachment by writ differs from distress, in not extending to lands, as the latter does; nor does a distress touch the body, as an attachment does.

In the common acceptance, an attachment implies the apprehension of a man's body, in order to his answering the action of the plaintiff.

ATTACHMENT out of the Chancery is obtained upon an affidavit made, that the defendant was served with a subpoena, and made no appearance; or it issueth upon not performing some order or decree. Upon the return of this attachment by the sheriff, *quod non est inventus in balliva sua*, another attachment, with a proclamation, issues; and if he still refuses to appear, a commission of rebellion.

ATTACHMENT of the Forest is one of the three courts held in the forest.

The lowest court is called the court of attachment, or wood-mote court; the mean, swan-mote; and the highest the justice in eyre's seat.

The court of attachments has its name from the verdurers of the forest having no other authority in it, but to receive the attachments of offenders against vert and venison taken by the foresters, and to enroll them, that they may be presented or punished at the next justice in eyre's seat.

This attachment is by three means; by goods and chattels, by body, pledges, or mainprize; or by the body only. This court is held every forty-days throughout the year; and is thence called forty-days court.

ATTACHMENT of Privilege is by virtue of a man's privilege to call another to that court where to he himself belongs, and in respect whereof he is privileged to answer some action.

Foreign ATTACHMENT is an attachment of money or goods found within a liberty or city, to satisfy some creditor within such liberty or city.

By the custom of London, and several other places, a man can attach money or goods in the hands of a stranger, to satisfy himself.

ATTACHAMENTA Bonorum, in our old statute books, imports a distress taken upon the goods or chattels of a person sued for a personal estate, or debt.

debt, by the legal attachiators, or bailiffs, as a security to answer the action.

ATTACHIAMENTA de Spinis & Bosca, denotes an ancient privilege granted to the officers of forests, to take to their own use thorns, brush, and windfalls within their own precincts or liberties.

ATTACK, a violent attempt upon any person or thing, an assault, or the act of beginning a combat, or dispute.

ATTACK, in the military art, is an effort made to force a post, break a body of troops, &c.

ATTACK of a Siege, is a furious assault made by the besiegers with trenches, covers, mines, &c. in order to make themselves masters of a fortress, by storming one of its sides. If there are two or three attacks made at the same time, there should be a communication betwixt them.

ATTAINDER, in law, is when a man has committed felony or treason, and sentence is passed upon him for the same. The children of a person attainted of treason, are thereby rendered incapable of being heirs to him, or to any other ancestor; and if he were noble before, his posterity are degraded and made base: nor can this corruption of blood be falved, but by an act of parliament, unless the sentence be reversed by a writ of error.

Attainder is two-fold, either by appearance, or by process.

ATTAINDER by appearance, is either by battle, by confession, or by verdict. By battle, is when the party appealed by another, choosing rather to try the truth by combat than by jury, is vanquished. Attainder by confession, is either by pleading guilty at the bar, and not putting himself upon trial by the jury, or before the coroner in sanctuary, where, in ancient times, he was obliged to renounce the realm.

ATTAINDER by verdict, is when the prisoner at the bar pleads not guilty to the indictment, and is pronounced guilty by the jury.

ATTAINDER by process, otherwise called attainder by default, is where a party flies, or does not appear after being three times publicly called in the county court, and at last, upon his default, is pronounced guilty.

Bill of ATTAINDER, a bill brought into parliament for attainting, condemning, and executing a person for high treason.

ATTAINT, in law, a writ which lies against a jury that have given a false verdict in any court of record, in a real or personal action, where the debt or damages amount to above forty shillings.

If the verdict be found false, the judgment, by common law, was, that the jurors meadows should be ploughed up, their houses broken down, their woods grubbed up, all their lands and tenements

forfeited, &c. but by statute the severity of the common law is mitigated, where a petty jury is attainted, and there is a pecuniary penalty appointed.

But if the verdict be affirmed, such plaintiff shall be imprisoned and fined.

ATTAINT, among farriers, a knock or hurt in a horse's leg, proceeding either from a blow with another horse's leg, or from an over-reach in frosty weather, when a horse being rough-shod, or having shoes with long calkers, strikes his hinder feet against his fore-legs.

ATTAINTED, in law, is applied to a person found guilty of any crime or offence, especially of treason or felony, by due course of law.

ATTENTION, the applying either the ear or the mind assiduously to any thing said or done, in order to understand it.

The word is Latin, *attentio*, and compounded of *ad*, to, and *tendo*, to stretch, or bend.

To increase attention, we must banish every thing that may interrupt it, and seek every means to strengthen and assist it. Our senses are apt to divert our attention; new sensations obscure, efface, and obliterate acts of imagination. Yesterday you saw a fine piece of painting, were so struck with it, that its idea quite possessed you; another, offered to your view to-day, drives the former out of your imagination; thus external objects destroy attention: for this reason some pray with their eyes shut, or directed steadily towards some fixed and immovable point. Students choose a room remote from noise and the interruption of external objects; and the studies of the night have been more successful than those of the day, because a more universal calm and silence reigns.

The hurry of the imagination destroys attention as much as that of our senses; after a play, it is difficult to resume our studies immediately; next day some images will recur, apt to divert us, and interrupt our attention. The senses, the imagination, and the passions operate upon the soul, and give it a kind of modification. All, therefore, who would apply themselves strenuously to the discovery of truth, should be careful to avoid strong and immoderate sensations, a great noise, a glaring light, excess of grief, or joy, &c. they ought to keep their imagination free from any thing that weakens or disquiets the mind. They ought especially to control their passions, which, let loose, make very powerful impressions on the soul and body, and exercise a strange dominion over both; yet the passions and the senses may be made of use to preserve our attention: as, for instance, a desire of discovering truth, rendering ourselves useful to our neighbours, and improving ourselves, is highly laudable, and tends to fix our attention;

but our attention is fixed also by motives much less generous and noble, a thirst of fame, desire of riches, nay, even vanity. Experience shews us the senses are of no small service to fix the attention; for they have a natural connection with our situation; a man, retired to meditate in a solitary cell, will be alarmed, distracted, and his attention entirely destroyed by an unexpected noise, or intermission of adventitious light; so, if we, on the contrary, reflect strongly on an object amidst daylight and noise, that idea banishes all others and possesses us; thus light and noise are no interruptions to attention, but serve to fix it more strongly. It is, in short, a habit of the mind: and the philosophers, who have shut their eyes to help their meditation, have furnished us with nothing but chimeras. Had Descartes kept his eyes open to have surveyed the universe with attention, instead of sinking into meditation, he would never have published such dreams as he has for a plan of the universe. Attention is progressive, and the power of it may be acquired, but depends, in some measure, on the constitution.

ATTENUANTS, in pharmacy, are medicines which resolve the viscosity of the humours in the human body, and thereby promote their free circulation, and, at the same time, discharge all noxious and excrementitious matter.

The word is formed from the Latin, *ad*, and *tenuo*, to render small.

ATTESTATION, the act of affirming, or witnessing, the truth of something, especially in writing.

The word is Latin, *attestatio*, and compounded of *ad*, to, and *testis*, a witness.

ATTIC, something relating to Attica, or the city of Athens. Thus, Attic salt, *sales Attica*, implies a delicate and poignant species of wit and humour peculiar to the Athenian writers: Attic witness, *Atticus testis*, a witness incapable of corruption, &c.

ATTIC, in architecture, a sort of building; the roof or covering of which is concealed; so called from the Athenian buildings, which were in general of this form.

Attic Order, in architecture, a small order raised upon a large one, by way of crowning, or to finish the building.

The word is also applied to the whole story into which this order enters.

Attic of a Roof, a kind of parapet to a terrace, platform, or the like.

Attic Continued, that which encompasses the whole circumference of a building, without any interruption, following all the jets, the returns of the pavilions, &c.

Attic Interposed, one situated between two tall stones, sometimes adorned with columns, or pilasters.

Attic Base. See the article **BASE**.

ATTIRE, in botany, a name given by some to the generative parts of plants; and by others, to imply the third part or division of the flower of a plant; the other two being the empalement and the foliation, or the cup and the flower petals.

ATTIRE, in hunting, signifies the head or horns of a deer. See the article **HEAD**.

ATTITUDE, in painting and sculpture, signifies the gesture of a figure or statue; or such a disposition of their parts as serves to express the action and sentiments of the person represented.

The word is formed from the Italian, *attitudine*, which signifies the same thing.

ATTOLLENS, in anatomy: see **LEVATORES** and **ELEVATORES**.

The word is compounded of the Latin, *ad*, to, and *tollō*, to raise.

ATTORNEY, in a general sense, a person appointed by another to do something in his stead.

The word is formed from the Latin, *ad*, to, and the French, *tourner*, to turn; q. d. to turn a business over to another.

ATTORNEY at Law, one who is retained to prosecute or defend a law-suit.

Attornies, being properly those who sue out writs, or process, or commence, carry on, and defend actions, in any of the courts of common law, are distinguished from solicitors, as the latter do the like business in the courts of equity; and none are admitted, either as an attorney or solicitor, unless they have served a clerkship of five years, been enrolled, and taken the oath in that case provided; and the judges of their respective courts are required to examine their several capacities.

By a late order of all the judges, all attornies are to be admitted of some inns of court or chancery (except house-keepers in London and Westminster, &c.); and no attorney shall put himself out of that society, into which he is admitted, till he is admitted to some other society, and deliver a certificate thereof; and all attornies are to be in commons at the times ordered by the society to which they belong, otherwise they shall be put out of the roll of attornies.

Attornies may be punished for ill practices; and if an attorney, or his clerks, of which he must have but two at one time, do any thing against the express rules of the court, he or they may be committed.

Neither a plaintiff nor defendant may change his attorney without rule of court, while the suit is depending; and attornies are not generally obliged to deliver up the writings in their hands, till their fees are satisfied: likewise, an action does not lie against an attorney, for what he advises in

the way of his profession; yet, if an attorney plead any plea, or appear, without warrant from his client, action of the case lies against him.

Attornies have the privilege to sue and be sued only in the courts of Westminster, where they practise; and they shall not be chosen into offices against their will.

ATTORNEY of the *Duchy of Lancaster* is the second officer in that court, and seems to be there, for his skill in the law, placed as assessor to the chancellor of the court.

ATTORNEY-GENERAL is a great officer under the king, created by letters patent, whose office is to exhibit informations, and prosecute for the crown in criminal causes; and to file the bills in the exchequer, for any thing concerning the king in inheritance or profits. To him come warrants for making of grants, pardons, &c. His salary from the crown is 1000l. per ann.

ATTORNMENT, in law, implies a transfer made from one lord to another, of the homage and service a tenant makes; or that acknowledgment of duty to a new lord.

ATTRACTION, in natural philosophy, an indefinite term applicable to all actions whereby bodies tend towards one another, by some latent power. The different kinds of attractions are commonly divided into four, viz. of Cohesion, of Electricity, of Gravity, and Magnetism.

ATTRACTION of *Cohesion* is that by which minute bodies, or the several particles of the same body when placed asunder, or at very small distances, mutually approach each other, and then adhere or stick together, as if they were but one body. This attraction is strongest when the parts of the bodies touch one another, but decreases much faster than the attraction of gravity, when the parts that were before in contact cease to touch; and when they become to be at any sensible distance, this attraction of cohesion becomes almost insensible.

The attraction of cohesion may be proved by a great number of experiments, of which some of the most obvious are as follows: First, Suppose a capillary tube, open at both ends, be put into a vessel of water, the water will immediately rise up in the tube to a certain height above the level. This rise of the water is manifestly owing to the attraction of those particles of the glass, which lie in the inner surface of the tube immediately above the water; for the quantity of water raised is always proportionable to the largeness of that surface; and the heights the water rises to in different tubes, are observable to be reciprocally as the diameters of the tubes; from whence it follows, that the quantities raised, are as the surfaces which raise them; which may thus be demonstrated. Let there be two tubes, the diameter of

the first double to that of the second, then will the water rise half as high in the first as in the second; for was it to rise equally high in both, the quantity in the first would be four times as great as in the second, cylinders of equal heights being as the squares of their diameters; therefore, since it is but found to rise half as high, the quantity is but twice as much, and therefore is as the diameter, but the surfaces of cylinders are as their diameters, therefore the quantities of water raised are as the surfaces.

Again, let two spheres of quicksilver be placed near each other, and they will immediately run together, and form one globule; but these spheres will not approach each other, except they are placed very near; from whence it is plain, that this kind of attraction only acts in contact, or at very small distances; likewise, by the following experiment, we may prove that it is always the strongest, where the contact is the greatest. Let two boards of fir, or oak, be glued in the middle along the grain, and it will be easier to break them asunder in any other part, than in the glued place; because there are more pores, and consequently fewer touching parts along the wood, any where else than there are in the glued part; for when a joint is shot, or the two pieces of wood made smooth in order to join them, the glue which is spread on the pieces fills the pores, and causes the wood not only to touch where it did before, but even in the interstices where it did not touch, because those little spaces are filled with glue, that supplies the place of wood. On the contrary, when the wood is more solid, or has fewer pores than the glue, it does not hold so fast where it is glued, as in the other parts of the wood, which may be seen in Brazil-wood, ebony, or lignum-vitæ, and in metals; likewise the parts of glass which are almost round, touching but in few points, are easily separated, and therefore it breaks easily. We may likewise prove by experiment, that this kind of attraction acts according to the breadth of the surfaces of the attracting bodies, and not according to their quantities of matter; for let there be polished glass plates laid one upon another in such a manner as to touch at one end, and there make a very small angle; then if two unequal drops of oil be put between those plates, at equal distances from the line of contact, so that the least may touch both glasses, they will then both move towards the ends that touch, because the attraction of the surfaces inclines that way; but the largest touching the glasses in most points, will move the fastest.

It is likewise observed, that this attraction of cohesion decreases, much more than that of the squares of the distances of the attracting bodies from each other increase; that is, whatever the force of attraction is, at a given distance; at twice that distance,

tance, it shall be more than four times less than before.

From the nature of the attraction of cohesion, we have a rational solution of several very curious and surprising phenomena; as why the parts of bodies adhere and stick so firmly together; why some are hard, others soft; some fixed, others fluid; some elastic, others void of elasticity: all which arise from the different figures of the particles, and the greater or lesser degree of attraction consequent thereupon. On this principle, we account for the manner how plants imbibe the nutritive juices by the fibres of the roots; also for the rise of the sap in vegetables, and for the whole economy of vegetation. Hence the rationale of the various secretions of fluids by the glands, and their wonderful circulation through the fine capillary vessels. Hence also the reason of soldering and gilding metals; also of melting, or fusion, by heat. Hence also the exhalation of vapours by the heat of the sun or fire; the aggregation of aqueous particles in the air, forming the drops of rain. We hence see the reason of distillation, filtration, dissolution, digestion, sublimation, precipitation, crystallization, and the other operations of chemistry and pharmacy. Lastly, it is by this power of attraction and repulsion, that we are to account for those wonderful phenomena of subterranean ascensions and explosions; of volcanos and earthquakes; of hot springs, damps, and suffocating exhalations in mines, &c. See the article-COHESION.

The second species of attraction is that of electrical bodies, as glass, amber, sealing-wax, jet, &c. for the properties of which see ELECTRICITY.

ATTRACTION of Gravitation is that by which distant bodies act upon each other. Of this we have daily instances in the falling of heavy bodies toward the earth.

The laws of this attraction are, First, That it decreases, as the squares of the distances between the centers of the attracting bodies increase. Thus, a body which at the surface of the earth (i.e. about the distance of four thousand miles from its center) weighs ten pounds, if it was placed four thousand miles above the surface of the earth, i.e. twice as far distant from the center as before, would weigh four times less; if thrice as far, nine times less, &c. The truth of this proposition is not to be had from experiments, (the utmost distance we can convey bodies to, from the surface of the earth, bearing no proportion to their distance from its center) but is sufficiently clear from the motions observed by the heavenly bodies. Secondly, Bodies attract one another with forces proportionable to the quantities of matter they contain; for all bodies are observed to fall equally fast in the exhausted receiver, where they

meet with no resistance. From whence it follows, that the action of the earth upon bodies is exactly in proportion to the quantities of matter they contain; for was it to act as strongly upon a less body as upon a larger, the least body, being most easily put into motion, would move the fastest. Accordingly, it is observable, that the weight of a body is the same, whether it be whole, or ground to powder.

From hence it follows, that, was a body to descend from the surface toward the center of the earth, it would continually become lighter and lighter, the parts above attracting it, as well as those below; in which case it is demonstrated by mathematicians, that the gravity would decrease with the distance of the body from the center.

Thus, Let there be a body as P, (Plate XVI. fig. 1.) placed any where within a concave sphere, as AB, which let us suppose divided into an infinite number of thin concentric surfaces; we say, the body P will be attracted equally each way by any one of these, *v.g.* the interior HIKLM. Let there be lines, as IL, HK, &c. drawn through any point of the body P, in such a manner as to form the surface of two similar figures, suppose cones, the diameters of whose bases may be IH, KL, which let be infinitely small. These bases (being as the squares of the lines IH, KL) will be directly, as the squares of their distances from P (for the triangles IPH, KPI, being infinitely small, are similar.) But those bases include all the particles of matter in the interior surface, that are opposite to each other; the opposite attractions are therefore in the same ratio with those bases, that is, as the squares of the distances PK, PI. But the attraction is inversely, as the squares of the distances of the attracting bodies, *i.e.* inversely as the squares of the same distances PK, PI; these two ratios therefore destroying each other, it is evident, that if the concavity of the sphere was filled with matter, that alone, which lies nearer the center than the body, can effect it, the respective actions of all the parts, that are more distant, being equal, and in contrary directions, since the same is demonstrable of any of the remaining concentric surfaces. Let us see then what effect that, which lies nearer the center than the body, will have upon it, which may be considered as a sphere, on whose surface the body is placed. The distances of each particle of matter from the body, (taken collectively) will be as the diameter of the sphere, or as the radius, *i.e.* as the distance of the body from the center: their action therefore upon the body will be inversely as the square of that distance: but the quantity of matter will be as the cube of that distance; the attraction therefore will be also in that proportion. Now, these two ratios being compounded, the attraction

traction will be only as the distance of the body from the center.

It may be proper to observe here, that when philosophers speak of beings gravitating to, or attracting each other, that body is said to gravitate to another, which moves towards it, while the other actually is, or appears to be, at rest, and this other is said to attract the former; though, indeed, the force being mutual and equal on both sides, the same term might be applied to either the gravitating or attracting body.

It is farther to be observed, that when we use the terms attraction or gravitation, we do not thereby determine the physical cause of it, as if it proceeded from some supposed occult quality in bodies; but only use those terms to signify an effect, the cause of which lies out of the reach of our philosophy. Thus, we may say, that the earth attracts heavy bodies; or that such bodies tend or gravitate to the earth; although at the same time we are wholly ignorant, whether this is effected by some power actually existing in the earth, or in the bodies, or external to both; since it is impossible any error in our reasonings can follow from hence; it being evident, that all the consequences of such tendency must be the same, let the cause be where or what it will.

All philosophers agree that there is a certain force by which the primary planets tend towards the sun, and the secondary planets towards their primary. As we ought carefully to avoid multiplying principles, and impulse is the most known and least controverted principle of the motion of bodies, it is clear, a philosopher would naturally attribute this impelling power to a fluid. To this notion, the vortices of Des Cartes owe their birth, and this opinion seemed more plausible, because it accounted for the motions of the planets by the circular motion of the matter of the vortices, and their tendency towards the sun by the centrifugal force of the same matter: but an hypothesis is not to be admitted, which accounts only for general phenomena; particular phenomena are the tests of an hypothesis, and the failure of the Cartesian system in those overturned it. The doctrine of vortices is therefore justly exploded, as so many difficulties attend it which never can be surmounted; for, if the planets move by virtue of the action of a fluid, this fluid must have contrary properties, it must impel in one intention, and in another make no resistance, an apparent absurdity; and the remedy is worse than the disease; for the force by which the planets tend towards the sun, must, on this hypothesis, be ascribed to an occult quality, which is saying nothing at all: and Aristotle, who perhaps invented the term, is much more pardonable than many modern philosophers who have blindly followed him.

We may therefore truly assert, that attraction is

a primordial quality of matter; nor is it perhaps possible to explain the celestial bodies on the principle of impulsion. Sir Isaac Newton seems to waver in some parts of his works concerning the nature of attraction, and admits of an impelling power; there is reason to think it was a kind of tribute he chose to pay to the prejudice, or rather the general opinion of the age he lived in, than his real sentiment; because he admitted Mr. Cotes, his disciple, to adopt attraction without reserve, as may be seen in the preface to his second edition of his *Principia*; and this preface was written under the eye of Sir Isaac, and had his approbation. Besides, Sir Isaac admits a reciprocal attraction among the celestial bodies, and this very opinion seems to suppose attraction a quality inherent in bodies; but be that as it may, according to Newton, the attractive force decreases in an inverse ratio to the squares of the distances: this learned philosopher has solved a great part of the celestial phenomena on this single principle, and all who have tried to account for them since, on the same principle, have succeeded to a surprising degree of exactness. The motion of the moon's apogee, which was pretended to be irreconcilable to this hypothesis, is now found to be entirely conformable to it, and does honour to the Newtonian system. All the other inequalities of the motion of the moon, which are very considerable, may also easily be accounted for by the system of attraction, and demonstrated by calculation.

All the phenomena hitherto observed, demonstrate a mutual tendency of the planets towards each other; wherefore, we must admit this for a truth on its own evidence: and though we should be forced to acknowledge this a primordial and inherent quality in matter, we may venture to say, that the difficulty of conceiving such a cause would be a very weak argument against its existence. No one doubts but that a body which meets another communicates motion to it; but have we an idea of the power by which this communication is made? The vulgar eye here, perhaps, penetrates as far as that of the philosopher. No body is surprized at seeing a stone fall; they have always seen it; philosophers, well acquainted with the effects of impulsion, have never troubled themselves about the cause which produces them. Now, if every body which meets another should stop without communicating motion to it, a philosopher would be as much astonished at this phenomenon, as a common man at seeing a heavy body suspended in the air. If we understand wherein the impenetrability of matter consists, we should not perhaps be clearer about the nature of the impelling power. We only see that, in consequence of this impenetrability, the shock of one body against another must be followed by some change, either in both or one of the bodies; but we know not, and perhaps never shall, by what power this change is effected; and why,

why, for instance, a body which strikes against another should not always continue at rest after the shock, without communicating a part of its motion to the body which resists it. It is apprehended attraction contradicts the notion we have of matter; but, if we enquire attentively, we shall find these ideas no way repugnant. The universe is concealed from us by a curtain, we see only some part of it; were that drawn up on a sudden, we should be surprized to see what passes behind it: besides, the pretended inconsistency of attraction with the nature of matter, is solved by admitting an intelligent Being, who could as easily ordain bodies to act on each other at a distance as in contact.

M. de Maupertuis, in his discourse on the figures of the planets, has given an idea of the system of attraction, with remarks on it: and the same author observes, in the Mem. Acad. 1734, that, long before Sir Isaac Newton, Roberval de Fermat and Pascal thought gravity an attractive power, and inherent in bodies. We will add, that Hook had the same notion, and foretold that all the motions of the planets would one day be accounted for on this single principle. These reflections, by increasing the number of great men who were of the same opinion with Sir Isaac, take nothing from his glory; for, as he was the first who actually demonstrated this principle, he is properly the author of it.

Attraction of Mountains. If it be admitted that all parts of the earth attract each other mutually, it must be granted that there are mountains on it, whose magnitude is considerable enough to make a sensible attraction. Let us suppose the earth a globe of an uniform figure, whose radius is equal to 1500 leagues, and suppose a mountain on the surface of some part of this globe one league in height, it is easy to demonstrate, that a weight placed at the bottom of this mountain shall be attracted horizontally by the mountain, with a force equal to a 3000th part of the weight; so that a pendulum or plumb line, placed at the bottom of this mountain, must deviate from a perpendicular about a minute; the calculation is not difficult, and this may be admitted by way of supposition: from whence it follows, that when we observe the elevation of a star at the foot of a great mountain, the plumb-line must deviate from a perpendicular; and an observation of this kind, certainly would afford a very strong proof in favour of the system of attraction: but it may be objected, how shall we be sure the plumb-line actually deviates from a perpendicular, as the direction of the plumb-line only determines the vertical situation of the star? This difficulty is easily surmounted.

Let us suppose a star on the north of the mountain, and the person who is to make his observation placed on the south: if the attraction of the

mountain acts sensibly on the plumb-line, it will deviate from a perpendicular towards the north; and, consequently, the apparent zenith of the star will go back towards the south; and so the distance of the star, on which the observation is made in the zenith, must be greater than if there was no attraction.

After having made this observation, if we go at a distance from the mountain, or a right line towards the east or west, so far that the attraction no longer operates, an observation made in this new station will shew the star at less distance than in the former.

But there is another and better method. It is certain, that, if the plumb-line on the south side of the mountain deviates towards the north, the plumb-line in the north side must deviate towards the south, and the zenith of the star, which in the first case went back towards the north, must, in the latter, advance towards the south: therefore, taking the difference of these two distances, and dividing it into two equal parts, will shew how much the pendulum has deviated from a perpendicular by the attraction of the mountain.

The whole theory is clearly explained, with several remarks, in an excellent Memoir of M. Bouguer's, printed in the year 1749, at the end of his book on the figure of the earth: in which he gives an account of the observations he made in company with M. Condamine, on the north and south sides of the great mountain Chimboraco, in Peru; the result of his observations is, that the attraction of this great mountain causes a deviation of the plumb-line from its perpendicular of 7" and a half. Mr. Bouguer judiciously remarks, that the greatest mountain is a trifle compared to the vast body of the terrestrial globe; and that a hundred observations where no sensible attraction is found, prove nothing against the Newtonian system; but that this made at the foot of the vast mountain Chimboraco, which is in favour of the doctrine of attraction, deserves the attention of all philosophers.

For the properties of the fourth kind of attraction, see **MAGNETISM**.

ATTRACTIVE, something that has the power or property of attraction.

ATTRACTIVES, or **ATTRACTIVE Medicines**, a name given by some writers to what are otherwise called *digestives*, *drawers*, &c.

ATTRIBUTE, in a general sense, means a quality or property that is inherent in some person or thing.

We may distinguish attributes into *proper* and *common*: when an attribute is founded on all the essential qualities of any being, it may be called *proper*; when it belongs only to some one or more of them, it is *common*. To illustrate this by an example: the equality of the three angles of every rectilinear triangle to two right ones, is a *proper attribute*,

tribute, because this equality is determined both by the number of the sides, and the particular kind of lines, that are essential properties of this triangle: but the number of angles in a triangle is only determined by the sides of the triangle; and therefore this is a *common attribute*, that happens in general to all figures of this kind, whether they are rectilinear triangles or curvilinear.

Of the several attributes of any subject, that which presents itself first, and which the mind conceives as the foundation of all the rest, is called its essential attribute. Thus extension is by some, and solidity by others, made the essential attribute of body or matter. The other attributes are called *accidental* ones, such as *figure*, *malleability*, &c.

ATTRIBUTES, in theology, are qualities or perfections in the Deity, which constitute his essence: such, for instance, are infinity, eternity, mercy, goodness, justice, omnipotence, immutability, &c.

The heathen mythology divided the Deity into as many distinct beings as he had attributes: hence arose that vast plurality of gods which over-ran the heathen world. The power of God was called Jupiter, his vengeance Mars, his wisdom Apollo, &c. These, however, were rather vulgar notions, adapted to the mean understandings of the populace, than believed by their philosophers; the wisest of whom thought that the one Supreme possessed all these qualities in their highest perfection, and yet remained at the same time uniform, simple, and harmonious.

ATTRIBUTES, in logic, are the predicates of any subject, or what may be affirmed or denied of any thing.

ATTRIBUTES, in painting and sculpture, signify the symbols added to several figures to intimate their particular office and character. Thus the eagle is the attribute of Jupiter; a peacock of Juno; a caduceus of Mercury; a club of Hercules; a trumpet of Fame; a balance of Justice; and a palm of Victory.

ATTRITION, in a general sense, implies the rubbing or striking of bodies one against another, so as to throw off some of their superficial particles.

The word is Latin, *attritio*, and derived from *attero*, to rub against.

The grinding or polishing of bodies is performed by attrition, the effects of which are heat, light, fire, and electricity.

ATTRITION is often used for the friction of such simple bodies as do not wear from rubbing against one another; but whose fluids are, by that motion, subjected to some particular determination; as the various sensations of hunger, pain, and pleasure, are said to be occasioned by the attrition of the organs formed for such impressions.

ATTRITION, among divines, signifies a sorrow or repentance for having offended God, arising

chiefly from the apprehensions of punishment, the loss of heaven, and the torments of hell; and differs from contrition, inasmuch as this last is conceived to arise from a love to God, as an ingredient or chief motive to our sorrow and repentance. See the article CONTRITION.

AVANT *Foss*, in fortification, is a moat or ditch full of water, running round the counter-scarp, on the outside next the country, at the foot of the glacis. It is not proper to have such a water ditch where it can be drained dry, because it is a trench ready made for the besiegers to defend themselves against the sallies of the besieged; besides, it hinders putting succours into the place, or at least makes it difficult so to do.

AVAST, amongst seamen; stop, hold.

AVAUNCHEERS, among hunters, the second branches of a deer's horn.

AUBIN, in horsemanship, a kind of broken pace, between an amble and a gallop. It is reckoned a defect.

AUCTION, *Auctio*, a kind of public sale, very much in use for household goods, books, plate, &c. By this method of sale, the highest bidder is always the buyer.

This was originally a kind of sale among the ancient Romans, performed by the public crier, *sub hasta*, i. e. under a spear, stuck up upon that occasion by some magistrate, who made good the sale by delivery of the goods.

AUDIANISM, the same with anthropomorphism, or the doctrine of the anthropomorphites. See the article ANTHROPOMORPHITES.

AUDIENCE, in a general sense; see the article HEARING.

AUDIENCE given to ambassadors, implies the ceremonies observed in courts, at the admission of ambassadors, or public ministers, to a hearing.

In England, audience is given to ambassadors in the presence-chamber; to envoys and residents, in a gallery, closet, or in any place where the king happens to be. Upon being admitted, as is the custom of all courts, they make three bows, after which they cover and sit down; but not before the king is covered and far down, and given them the sign to put on their hats.

When the king does not care to have them covered, and sit, he himself stands uncovered; which is taken as a slight.

At Constantinople ministers usually have audience of the grand vizier.

AUDIENCE is also the name of a court of justice established in the West-Indies by the Spaniards, answering in effect to the parliament in France.

These courts take in several provinces, called also audiences, from the names of the tribunal to which they belong.

AUDIENCE is also the name of an ecclesiastical court held by the archbishop of Canterbury, where-

in differences upon elections, consecrations, institutions, marriages, &c. are heard.

AUDIENDO & TERMINANDO, a writ, or more properly a commission, directed to certain persons, when any riotous assembly, insurrection, &c. is committed in any place, for appealing it, and punishing the offenders.

AUDIENTS, an order of catechumens, in the primitive Christian church, consisting of such as were but newly instructed in the mysteries of the Christian religion, and not yet admitted to baptism.

AUDIT, a regular hearing and examination of an account by some proper officers appointed for that purpose.

AUDITA QUERELA, a writ that lies usually where one is bound in a statute merchant, statute staple, or recognizance, when a person has any thing to plead, but hath not a day in a court for pleading it; or where judgment is given for debt, and the defendant's body in execution; then, if he have a release, or other sufficient cause to be discharged therefrom, but wants a day in court to plead the same, this writ may be granted him against the person that has recovered, or against his executors.

This writ is granted by the lord chancellor, upon view of the exception suggested to the judges of either bench, willing them to grant summonses to the sheriffs of the county where the creditor is, for his appearance, at a certain day, before them.

AUDITOR, in a general sense, a hearer, or one who listens and attends to any thing.

AUDITOR is also used for several officers appointed to audit. See **AUDIT**.

It was antiently used for a judge. Notaries are also frequently called *auditores*.

AUDITOR, according to our law, is an officer of the king, or some other great person, who, by examining yearly the accounts of the under-officers, makes up a general book, with the difference between their receipts and charges, and their allowances or allocations.

AUDITOR of the Receipts is an officer of the exchequer, who files the tellers bills, makes an entry of them, and gives the lord-treasurer a certificate of the money received the week before. He also makes debentures to every teller before they receive any money, and takes their accounts. He keeps the black-book of receipts, and the treasurer's key of the treasury, and sees every teller's money locked up in the new treasury.

AUDITORS of the Revenue, or of the *Exchequer*, officers who take the accounts of those who collect the revenues and taxes raised by parliament, and take the accounts of the sheriffs, escheators, collectors, tenants, and customers, and set them down in a book and perfect them.

AUDITORS of the press and impress, are officers of

the exchequer, who take and make up the account of Ireland, Berwick, and the Mint, and of any money impressed to any man for the king's service.

AUDITORS Collegiate, Conventual, &c. officers formerly appointed in colleges, &c. to examine and pass their accounts.

AUDITORY, something relating to the sense of hearing. See the article **HEARING**.

AUDITORY, or **AUDIENCE**, an assembly of people who attend to hear a person that speaks in public.

AUDITORY is also used for the bench whereon a magistrate or judge hears causes.

AUDITORY was also the place in ancient churches where the congregation stood to hear sermons.

Meatus Auditorius, auditory passage, in anatomy; see **MEATUS Auditorius**.

AUDITORY Nerves, in anatomy, a pair of nerves arising from the medulla oblongata, with two trunks, the one of which is called the *portio dura*, or hard portion, the other *portio mollis*, or soft portion. See the article **NERVE**.

The *portio mollis* enters the foramen of the os petrosus, and thence through various little apertures, gets into the labyrinth of the ear, where it expands over all its parts, and constitutes the primary organ of hearing.

The *portio dura*, passing the aqueduct of Fallopius, turns back one or more branches from the anterior surface of the process of the petrosus, into the cavity of the cranium. It sends off also another branch internally, which with the branch from the fifth pair, serves for the construction of the chorda tympani. It also sends off a number of other small ramifications, which run to the muscles and other parts of the tympanum.

AVE-MARIA, the angel Gabriel's salutation of the Virgin Mary, when he brought her the tidings of the incarnation.

It is become a prayer, or form of devotion, in the Romish church. Their chaplets and rosaries are divided into so many ave-maries, and so many paternosters, to which the papists ascribe a wonderful efficacy.

Dr. Bingham observes, that among all the short prayers used by the primitive Christians before their sermons, there is not the least mention of an *avemaria*.

AVENA, the *OAT*, in botany; see the article **OAT**.

AVENACEOUS, in botany, something belonging to, or partaking of the nature of the oat.

AVENOR, an officer belonging to the king's stables, who provides oats for the horses. He acts by warrant from the master of the horse. See the article **MASTER of the Horse**.

AVENUE,

AVENUE, in gardening, is a broad walk leading to an house, wood, &c. planted on each side with trees, and generally terminated with some distant object.

Avenues were formerly more in request than at present, for of late they are with good reason disused, as nothing can be more absurd than to have the sight contracted by two or more lines of trees, which shut out the view from all parts, except between the lines. The usual width formerly allowed to these avenues was equal to the breadth of the house, but if planted twelve or fourteen feet wider, the trees will not only grow better, but also enlarge the view; as to the distance from each other in the row, they should not be planted nearer than thirty-five or forty, especially if the trees are of the spreading kind. As to the trees which are proper for planting avenues, viz. the English elm, the lime-tree, the horse-chestnut, the common chestnut, the beech, and the poplar; the English elm will do in moist grounds, except such as are very moist and shallow; therefore, it is preferable to all other trees, because it will bear cutting, heading, or lopping in any manner, better than most others; a specimen of the growth and beauty of elm-trees, planted in avenues, may be seen in Greenwich-park: the lime-tree is valuable for its regular growth and fine shade, therefore not improper for this purpose: the horse and eatable chestnut also makes a grand appearance, as may be seen in the aforesaid park, and other places: the beech is a beautiful tree, but is apt to miscarry by transplanting: lastly, the poplar, or aale, is fit for any soil, and is a quick grower; it succeeds very well in wet soils, in which others are apt to fail.

The old method of planting avenues being much exploded, we have at present a much grander way by planting the trees in clumps, or platoons, making the opening much wider than before, and placing the clumps of trees at about three hundred feet distant from each other; in one of these clumps, there should be planted seven or nine trees, at about thirty feet asunder; but this is only to be practised, where the avenue is of a considerable length. The avenues made by clumps are fittest of all for parks, as they not only appear very beautiful, but when grown up afford a good shade for the deer in hot weather; but when young, a trench should be made round them, to prevent the deer coming to the trees to bark them.

AVENUE, in fortification, an opening or inlet into a fort, bastion, or the like. See the article **BASTION**.

AVERAGE, in law, an ancient service which the tenant owed to his lord by horse or carriage.

AVERAGE, in commerce, signifies the accidents and misfortunes which happen to ships and their cargoes, from the time of their loading and sailing, to their return and unloading; and it is divided

into three kinds. 1. The simple or particular average, which consists in the extraordinary expences incurred for the ship alone, or for the merchandizes alone. Such is the loss of anchors, masts, and rigging, occasioned by the common accidents at sea; the damages which happen to merchandizes by storm, prize, shipwreck, wet or rotting; all which must be borne and paid by the thing which suffered the damage. 2. The large and common average, being those expences incurred, and damages sustained for the common good and security both of the merchandizes and vessels, consequently to be borne by the ship and cargo, and to be regulated upon the whole. Of this number are the goods or money given for the ransom of the ship and cargo, things thrown overboard for the safety of the ship, the expences of unlading for entering into a river or harbour, and the provisions and hire of the sailors, when the ship is put under an embargo. 3. The small averages, which are the expences for towing and piloting the ship out, or into harbours, creeks, or rivers, one third of which must be charged to the ship, and two thirds to the cargo.

Average is more particularly used for a certain contribution, that merchants make proportionably towards their losses. It also signifies a small duty which those merchants, who send goods in another man's ship, pay to the master for his care of them over and above the freight. Hence it is expressed in the bills of lading, paying so much freight for the said goods with prime and average accustomed.

AVERAGE, in agriculture, a term used by the farmers in many parts of England, for the breaking of corn-fields, eddish, or roughings.

The word in the first or law sense is derived from *averium*, a labouring beast: in the second, or mercantile sense, from *averia*, goods, or chattels; from the French, *avoir*, to have or possess. In the last, or the farmer's sense, it may be derived from *haver*, an English name for oats.

AVER-CORN, that conveyed to the lord's granaries by his tenants.

AVERDUPOIS, or **AVERDUPOISE Weight**, a weight much used in England, and whose pound consists of sixteen ounces. See the article **WEIGHT**.

AVERIA, a general name for cattle of any kind; but, in law, is confined to oxen and horses of the plough.

AVER-LAND, that ploughed by the tenants for the use of their lord.

AVERMENT, an offer of the defendant to make good an exemption pleaded in abatement, or bar of the plaintiff's action.

General **AVERMENT** is the conclusion of every plea to the writ, or in bar of replications, or other pleadings, containing affirmative matter.

Particular AVERMENT is when the life of a tenant for life, or a tenant in tail, is averted.

AVERNI, among the ancient naturalists, implied certain lakes, grottoes, and other places, which infect with poisonous steams or vapours.

AVER-PENNY, money paid instead of a-verage.

AVERRHOA, in botany, a genus of plants, whose flower consists of five lanceolated petals, and ten filaments, with roundish antheræ; the fruit is an apple of a turbinated and obtuse pentagonal figure, containing five cells, in which are disposed angular seeds, separated by membranes.

AVERRHOISTS, a sect of Peripatetic philosophers, who appeared in Italy some time before the restoration of learning, and attacked the immortality of the soul.

They took their denomination from Averrhoes, a celebrated interpreter of Aristotle, born at Cordova in Spain, in the 12th century, from whom they borrowed their distinguishing doctrine. The founder of this sect, Averrhoes, is sometimes called the Commentator, by way of eminence, as being supposed to have entered best of all the commentators into the sentiments of that philosopher; inasmuch that some have pretended the soul of Aristotle had migrated into the body of Averrhoes.

The Averrhoists, who held the soul was mortal, according to reason or philosophy, yet pretended to submit to the Christian theology, which declares it immortal. But the distinction was held suspicious; and this divorce of faith from reason was rejected by the doctors of that time, and condemned by the last council of the Lateran, under Leo X. yet it was still secretly maintained. Pomponatius, Cæsalpinus, and others, were suspected of favouring this opinion: but the corpuscular philosophy, now introduced into Italy, seems almost to have extinguished Averrhoism.

AVERRUNCATION, in the ancient agriculture, signified the same with pruning. See the article **PRUNING**.

AVERRUNCI, in the ancient mythology, an order of deities, whose peculiar office it was to avert misfortunes. Apollo and Hercules were of this order among the Greeks, and Castor and Pollux among the Latins.

The word is Latin, and compounded of *a*, from, or away, and the obsolete verb, *verrunco*, to turn.

AVERTI, in the manege, implies such a pace in a horse as is regulated and required in the lessons.

AUGES, in astronomy, the same with apsidēs. See **APSIDES**.

AUGMENT, *Augmentum*, in grammar, an accident of certain tenses of Greek verbs, being either the prefixing a syllable, or the increase of the quantity of the initial vowels.

There are two species of augments, distinguished by the epithets *temporale* and *syllabicum*. The *augmentum temporale* is when a short vowel is changed into a long one, or a diphthong into another of greater length: an *augmentum syllabicum* is when a syllable is added at the beginning of a word.

AUGMENTS, in mathematics, the same with increments. See **FLUXIONS** and **INCREMENTS**.

AUGMENTATION, in a general sense, implies the act of adding or joining something to another, in order to increase its magnitude, or render it more considerable.

The word is Latin, *augmentatio*, and derived from *augere*, to increase.

Court of AUGMENTATION, a court erected in the 27th year of Henry VIII. to take care that the revenues of the crown were properly augmented by the estates arising from the suppression of religious houses. This court was dissolved in the first year of the reign of queen Mary; but the office, in which are many valuable records, still remains.

AUGMENTATION, in heraldry, are additional charges to a coat armour, frequently given as particular marks of honour, and generally borne either on the escutcheon or a conton. Thus all the baronets of England bear the arms of Ulster in Ireland.

AUGRE, or **AWGRE**, an instrument used by carpenters, millwrights, &c. for boring large round holes. It consists of a wooden handle and an iron blade, terminated with a steel bit.

AUGURS, among the old Greeks and Romans, were officers appointed to foretell future events by the chattering and feeding of birds, &c. There was a college, or community of them, consisting originally of three members, with respect to the three tribes, the Luceres, Rhamnenses, and Tatienses: afterwards the number was increased to nine, four of them patricians, and five plebeians: this was in the consulship of M. Valerius, and Q. Apuleius. They bore an augural staff, or wand, as the ensign of their authority. Cicero was of the college of Augurs.

AUGURY, in its first and proper sense, the art of foretelling future events by the chattering, singing, and feeding of birds; but in its more general signification, comprising all the different kinds of divination; which Varro distinguishes into four sorts, according to the four elements; viz. Pyromancy, or augury by fire; Aeromancy, or augury by air; Hydromancy, or augury by water; and Geomancy, or augury by the earth. It was a very ancient superstition; for we find it forbidden by Moses. It was in great esteem among the Chaldeans, from whom the Greeks learned it; and from them the Tuscans had so high a value for this art, that, by a decree of the senate, it was ordered, that the advice of the augurs should be held sacred, and never deviated from. But what

Z z z opinion

opinion the wiser Romans had of the art, appears from the saying of Cato, recorded by Cicero, That he wondered how two augurs could meet, without laughing in each other's face.

The place from whence auguries were taken, was a rising ground; and Servius, on Virgil, observes, that there was a field set apart for it, at a little distance from Rome. When all things were disposed for taking an augury, the augur entered into his tent or pavilion, habited in his robe, and holding his augural staff in his hand; with which he divided the heavens into four parts, drawing a line from east to west, and another cross it from north to south: then he sacrificed to the gods, and offered up a prayer; after which he returned to his seat, and observed with great attention from what part, and in what manner, the sign from heaven appeared. If, for instance, there happened lightning, or a clap of thunder, from the left, it was taken for a favourable presage.

But the principal kind of augury, and from which it has its name, was the observation of birds; to which the ancients were so superstitiously addicted, that they never would undertake any thing of the least importance, without consulting these feathered oracles. The invention of this art is by some ascribed to Prometheus; by others to Orpheus.

The Romans, whenever they went to war, not only consulted the chattering and flight of birds, but their manner of feeding likewise; for which purpose they kept poultry, which they commonly fetched from the island of Eubœa. When they would take a presage from thence, they flung corn before them: if the sacred chickens crowded about it, and ate it greedily, it was looked upon as a favourable omen; but if they refused to eat or drink, it was an unlucky sign.

AUGUST, in chronology, the eighth month of the year, according to our method of computing, beginning with January: but it was the sixth with the Romans, who for that reason called it Sextilis; which name was changed to August, from Augustus Cæsar, because this emperor, being returned from the Gauls in the 746th year of Rome, endeavoured to reform the calendar; and, in honour of him, Sextilis was changed to August. Others allege, the reason was, because he was first made consul in this month, and because he gained great victories in it. The Turks have also taken this name from the Greek or Roman calendars, since they call it Agostos.

AUGUSTALES, in Roman antiquity, an epithet given to the flamens or priests appointed to sacrifice to Augustus, after his deification, and also to the ludi or games celebrated in honour of the same prince, on the fourth of the ides of October.

AUGUSTALIA, a festival instituted by the Romans, in honour of Augustus Cæsar, on his return to Rome, after having settled peace in Sicily, Greece, Syria, Asia, and Parthia; on which occasion they likewise built an altar to him, inscribed *Fortunæ reduci*.

AUGUSTALIS PRÆFECTUS, a title peculiar to a Roman magistrate who governed Egypt, with a power much like that of a pro-consul in other provinces.

AUGUSTAN, in a general sense, denotes something relating to the emperor Augustus. Thus, we say, Augustan age, Augustan æra, &c.

AUGUSTIN MONKS, a religious order in the church of Rome, who follow the pretended rule of St. Augustin, prescribed them by pope Alexander IV. in the year 1256. There had arisen several religious orders in the thirteenth century; as the preaching brothers, founded by Dominic Guzman; the minims, by St. Francis Assisus; and others. Innocent IV. formed a design of uniting several of these orders into one; which design was executed by his successor Alexander IV. who made one congregation of them, under the name of Augustin hermits.

At present the order is divided into several branches; as the hermits of St. Paul; the Ieronimitans; the monks of St. Bridget; and the barefooted Augustins, instituted by a Portuguese, in 1574, and confirmed by pope Clement VIII. in 1600. As to the rule of St. Augustin, which they pretend to follow, it is briefly this: The monks are to have all things in common: the rich, who enter into the order, are to sell their possessions, and give them to the poor: nothing is to be received, without leave of the superior; if it happens that the monks are obliged, through persecution, to retire, they are to betake themselves immediately to the place whither their superior is withdrawn: they are to employ the first part of the morning in labouring with their hands, and the rest in reading: they have Saturday allowed them to provide themselves with necessaries, and are permitted to drink wine on Sundays. When they go abroad, they must always go two in a company: they are never to eat but in their monastery: they are forbidden to harbour the least thought of women: they are to receive no letters or presents in secret. These, with several other precepts relating to charity, modesty, chastity, and other Christian virtues, constitute what they call the rule of St. Augustin, which is read in the presence of the monks once every week. The Augustins are clothed in black. At Paris, they are known under the name of the religious of St. Genevieve, that abbey being the chief of the order. There are nuns likewise of this order.

AUGUSTINUS, the name of Jansenius's treatise,

treatise, from which are collected the five famous propositions enumerated under the article Janfenism. See JANSENISM.

AVIARY, a place set apart for feeding and propagating birds. It should be so large, as to give the birds some freedom of flight; and turfed, to avoid the appearance of foulness on the floor.

AVIS, the name of an order of knighthood in Portugal, instituted by Sancho the first king, in imitation of the order of Alcantara, whose green cross they wear.

AULA is used for a court baron, by Spelman; by some old ecclesiastical writers, for the nave of a church, and sometimes for a court-yard.

AULIC, an epithet given to certain officers of the empire, who compose a court, which decides, without appeal, in all processes entered in it. Thus we say, aulic council, aulic chamber, aulic counsellor.

The aulic council is composed of a president, who is a catholic; of a vice-chancellor, presented by the archbishop of Mentz; and of eighteen counsellors, nine of whom are protestants, and nine catholics. They are divided into a bench of lawyers, and always follow the emperor's court, for which reason they are called *justitium imperatoris*, the emperor's justice, and aulic council. The aulic court ceases at the death of the emperor; whereas the imperial chamber of Spire is perpetual, representing not only the deceased emperor, but the whole Germanic body, which is reputed never to die.

AULIC, in the Sorbonne and foreign universities, is an act which a young divine maintains upon being admitted a doctor in divinity.

It begins by an harangue of the chancellor, addressed to the young doctor, after which he receives the cap, and presides at the aulic, or disputation.

AULNEGER, or ALNAGER. See the article ALNAGER.

AULOS, αὐλός, a Grecian long-measure; the same with stadium. See STADIUM.

AUMBRY, a country word denoting a cupboard. See CUPBOARD.

AUME, a Dutch measure for Rhenish wine, containing forty English gallons.

AUNCEL-WEIGHT, an ancient kind of balance, now out of use, being prohibited by several statutes, on account of the many deceits practised by it. It consisted of scales hanging on hooks, fastened at each end of a beam, which a man lifted up on his hand. In many parts of England, auncel-weight signifies meat sold by the hand, without scales.

AUNE, a long measure used in France to measure cloth, stuffs, ribbons, &c.

At Rouen it is equal to one English ell, at Ca-

lais to 1. 52, at Lyons to 1. 016, and at Paris to c. 95.

AVOCADO Pear. See LAURUS.

AVOCATORIA, a mandate of the emperor of Germany, addressed to some prince, in order to stop his unlawful proceedings in any cause appealed to him.

AVOIDANCE, in the canon law, is when a benefice becomes void of an incumbent, which happens either in fact, as by the death of the parson, or in law, as by cession, deprivation, resignation, &c. In the first of these cases, the patron must take notice of the avoidance, at his peril; but in avoidance by law, the ordinary is obliged to give notice to the patron, in order to prevent a lapse.

AVOWEE, one who has a right to present to a benefice. See ADVOWSON.

He is thus called in contradistinction to those who only have the lands to which the advowson belongs for a term of years, or by virtue of intrusion or disclaim. See the article INTRUSION, &c.

AVOWRY, in law, is when a person distrained sues a replevin; for then the distrainer must avow, and justify his plea, which is called his avowry. See the article REPLEVIN.

The avowry must contain sufficient matter for judgment to have return, but so much certainty is not required therein, as in a declaration; and if made for rent, though it appears that part of that rent is not due, yet the avowry is good for the rest.

AURA, in chemistry, a certain fine and pure spirit, found in every animal or vegetable body; but so subtle, as only to be susceptible by its smell and taste, or other effects, not found in any other but that body. This aura exhibits the proper characters of the body, by which it is accurately distinguished from all others; but is itself too fine and thin to be seen by the eyes, though armed with a microscope, or felt by the hands; and, withal, is extremely volatile; so that, when pure and single, it flies off by its great mobility; mixes with the air, and is received into the great chaos of all volatiles; and there, still retaining its same nature, it floats till it falls down in snow, hail, rain, or dew, when it again enters the bosom of the earth, impregnates it with its prolific virtue, and is at length received by other juices of the earth, and conveyed into the bodies of animals and vegetables; and, by this revolution, passes into new bodies, whose mass it animates and directs. The subtle fluid is lodged in the oil of the body, to prevent its being dissipated and thrown off; and hence it is, that all the ancient alchymists say, spirit resides in sulphur. *Borr. Chem.*

AURANTIUM, in botany, the orange. See the article ORANGE.

AURELIA, in natural history, the same with what

what is more usually called chrysalis, and sometimes nymph. See the articles *CHRYSLIS* and *NYMPH*.

AURELIANA, in botany, a name given by some to the panax, or alheal. See the article *PANAX*.

AUREOLA, in its original signification, signifies a jewel which is proposed as a reward of victory in some public dispute. Hence the Roman schoolmen applied it to denote the reward bestowed on martyrs, virgins, and doctors, on account of their works of supererogation: and painters use it to signify the crown of glory, with which they adorn the heads of saints, confessors, &c.

AUREUS, a Roman gold coin, equal in value to twenty-five denarii.

According to Ainsworth, the aureus of the higher empire weighed near five penny-weight; and in the lower empire, little more than half that weight. We learn from Suetonius, that it was customary to give aurei to the victors in the chariot-races.

AURICLE, in anatomy, that part of the ear which is prominent from the head, called by many authors *auris externa*. See the article *EAR*.

AURICLES of the Heart. These are a kind of appendages of the heart at its base, and are distinguished by the names of the right and left. The right auricle is much larger than the left, and this is placed in the hinder, than in the anterior part. They are intended as diverticula for the blood, during the systole. Their substance is muscular, being composed of strong fibres, and their motion is not synchronous, but achronous with that of the heart. See the article *HEART*.

AURICULA Urss, bear's ear, in botany, a genus of pentandrious plants, classed with the *primula veris*, or primrose, by Dr. Linnæus; but, as they are very different both in their foliage and flowers, and are looked upon in common as distinct genera, it may therefore be proper to treat on them separately.

The auricula plant has, of late years, been cultivated with extraordinary care and pains by the curious in gardening, being greatly esteemed, as it produces a flower of exceeding beauty, which is diversified with a greater variety of colours, and exhibits more properties to complete the idea in the fancy of a florist, than any other species of the blooming vegetable tribes. The flower consists of a bunch, or truss, of petala, by florists called pippes, supported by as many pedicles, or foot-stems, arising out of the top of the main stalk: the properties of a fine auricula may therefore be well distinguished and divided, 1st, into those that regard the pippes; 2dly, those which respect the bunch, or truss; and, 3dly, those which belong to the main stalk.

1st, Of the Pippes.

The petals, or pippes, of an auricula have four remarkable parts; viz. the disk, or outer rim, the eye, or inner rim, the tube or pipe, and the brush, or thrum, so termed in the florists language, but by botanists called filaments, and antheræ. The properties belonging to the perfection of the pippes, are,

1. The disk, or rim, to be of a lively and good colour or colours, such as may suddenly strike and captivate the sight, for this property is the foundation of all the rest; it is that which makes a flower valuable at all, or to be preferred before the grass or foliage of the plant that bears it; if the colours, therefore, make a faint or dead appearance, or are of an inelegant or ordinary tinge, or hue, such flower is not good, even though all its other properties should be the most excellent, because all the rest are not otherwise of any account, but as they assist in the more full and perfect display of this chief one of colour.

2. The colours (in all painted and brindled flowers) ought to be so equally distributed over the rim or disk, that there may be an agreeable uniformity amidst the variety; so that, upon the whole, the sight may not be offended with any disproportion, or see one side remarkably of a lighter or darker hue than another.

3. The outward-edge of the rim ought to be of a circular figure, or at least so near it as that the indentures may bear but a small proportion to the breadth of the disk; for when these are deep and wide, and the points of the segments stand in the form of a star, greatly divided, the vacancies will offend the sight with an obvious deficiency and want: the case is still worse in those pippes which are subject to run out into a greater breadth on one side of the eye than on the other; this irregularity and disproportion is very disagreeable.

4. The eye (which is the annulus that environs the tube or pipe) ought to be formed like the disk, either perfectly or nearly round, and of one entire clear colour, of a strong and pure white in all painted or brindled flowers, and either the same, or of a bright yellow, or good straw colour, in whole coloured flowers.

5. The eye should be well defined from the disk, that is, it ought not to be mixed with, or shaded into, it, so as to occasion any indistinctness between the edge of one or the other.

In flowers where these two properties of the eye are imperfect, the lively contrast betwixt the rim and the eye (which otherwise reciprocally shew each other to advantage) is in a great measure destroyed. Though they may be allowed, in some measure, to be blended by the fine meal or powder which

which most auriculas have a share of, but not so much as to render the edges indistinct.

6. The face of the whole pipp (disk and eye) ought to be so well opened as to lie exactly or nearly flat, for when either it inclines inward, which is called cupping, or throws its extremity backward, both the true form of the flower and part of the colours are thrown out of sight, and the whole trufs is greatly disfigured.

7. The tube or pipe should stand exactly in the center of the pipp, and be truly circular, or round.

8. The tube should be well filled with filaments and antheræ, in the form of a brush, generally called the thrum, arising even with the face of the pipp; for when only the style rises like a pin, without being encompassed with the apices to the same height, the flower is called pin-eyed, and shews a chafin or vacancy so very unpleasant to the curious eye of a florist, that such flowers, though they may otherwise have good properties, yet, failing in this central beauty, they are held but of very small account.

9. The thrum should be of a bright colour, and the filaments and antheræ of which it is composed, clear and distinct; for when they seem clotted together, or appear misshapen, or of a dull colour, the beauty of the flower is much hurt and impaired.

10. The rim, the eye, and the pipe, ought all to bear an agreeable proportion to one another; for where any one of these is beheld either too large or too small with respect to the other two, it will give the sight of a florist great offence: thus if the rim is too large, the whole pipp will look heavy and clumsy, and the eye will appear narrow and mean; if the rim is too small, it will look abortive, and the eye monstrous; also, if the pipe is too wide, the thrum cannot fill it duly, and it will appear vacant; if the pipe is too small or narrow, it will seem pinched, and the thrum will not have room; so that there will be an apparent want of due grace, air, and freedom: perhaps the best proportions may be observed where the semi-diameter of the pipe is one, the breadth of the annulus of the eye one, and the breadth of the disk or rim one and a half.

2d. Of the Bunch, or Trufs.

11. It is an excellent property of an auricula to be a good trusser, that is, one which generally puts forth a great number of pippes from the main stalk, for by that means the beauty of the flower is greatly magnified, and makes in the whole a most delightful appearance.

12. The length of the pedicles which support the pippes in the trufs should be proportioned to the number and size of the pippes they sustain; for if the pedicles are very long, and the pippes few and small, there will be unsightly vacancies in the trufs; or if they are short, and the pippes many and large,

they would too much crowd together, so that neither the colours can be fully viewed, nor the other properties of the pippes fully displayed.

13. The pedicles should be sufficiently strong and firm, that they may not droop with the weight of the pippes, nor fall loose in a disorderly manner, but support the trufs entire and close, without either vacancy or crowding, so as to appear one complete free-blown flower.

14. The pedicles ought to be near all of the same length, so that the pippes may stand together, at the like height, and form a regular umbel, or rather corymbus, which is the formal perfection of the trufs.

15. The pippes should be all similar, that is, so near of the same size and colour as not to be easily distinguished from each other; for otherwise the unity and harmony of the trufs will be destroyed, and, though ever so perfectly formed, it will appear as if it were made up of pippes taken from different sorts of auriculas.

16. It is an exceeding good property of an auricula to blow freely, and expand all its pippes nearly at the same time, for by this means the colours in them all will appear equally fresh and lively; whereas in those which do not blow some of their pippes till others have passed their prime, the whole appearance of the trufs falls much short of that beauty which would otherwise be seen.

3d. Of the main Stalk.

17. The stalk which supports the trufs ought to be strait and sufficiently strong to bear it up without drooping.

18. It is an excellence of the stalk to be lofty as well as erect, for thereby the trufs, and consequently the whole flower, will make a more stately and grand appearance.

To these eighteen properties, which complete the florists idea of a beautiful auricula, there ought to be added, the graceful display of a good plant, covering the top of a flower-pot with fresh verdure or foliage of luxurious growth, and an agreeable green colour, such as is expressive of the most perfect health and vigour: this vastly enriches the whole view of the flower and plant taken together. Moreover, though every auricula that has the above-mentioned properties, cannot fail pleasing the most curious and critical florists, yet as, upon one hand, an auricula may be somewhat deficient in several particulars of small consideration, and yet be justly esteemed a fine and valuable flower; so, on the other hand, it will be a farther addition to the excellence of an auricula which has all the properties, that it naturally stands long in bloom, and wears its colours without fading or alteration; and also when the flower begins to decay (as decay it must, like all other terrestrial beauties) if the colours fade equally, slowly, and gradually, the florists think it an addition to

its character, and is by them termed dying well. Auriculas are propagated either by sowing their seeds, or by planting their off-sets. In order, therefore, to obtain good flowers from seeds, choice must be made of the best flowers, which should be exposed to the open air, that they may have the benefit of flowers, which is necessary for their producing good seeds. The time of their ripening is in June, which is easily discovered by their seed-vessel turning to a brown colour and opening, when they must be gathered before they are lost on the ground. The time of sowing these seeds is from August to Christmas. The best soil for sowing these seeds is in good fresh earth from a common, rather light, mixed with very rotten dung and leaves, which should be previously prepared: with this compost the pots or tubs, in which the seeds are intended to be sown, should be filled. Having levelled the surface of the earth very smooth, sow the seeds thereon, covering it very lightly with rotten willow mould, taken out of the stems of decayed hollow willow trees, after placing a net or wire over the earth, which will prevent the seed from being disturbed by cats, fowls, &c. The boxes or tubs should be situated where they can only receive the morning sun. In the spring following the young plants will come up, when they must be frequently refreshed with water in dry weather till July, when they will be large enough to transplant; at which time, with the aforesaid preparation of earth, plant them in beds or boxes, about three inches asunder, shading them from the sun in hot weather. The spring following many of these plants will shew their flowers, when those that answer the properties above described may be taken up and transplanted into pots of the smallest size; for if they have too large pots, they will not so well thrive. Those flowers which are not esteemed may be planted in the flower garden, where they will make a shew, and serve for nosegays, &c. Those which do not shew their flowers should be taken up, and planted in a fresh bed, to remain till the next season, when their goodness may be judged of. The manner of propagating these flowers from slips or off-sets, is to take them off in April, when the old plants are in bloom, and planted in small pots, in the same sort of earth as before directed, and, during the summer season, should be set in a shady place, and frequently refreshed with water, but should be protected from violent rains, which may fall in autumn, and in winter should have very little wet fall on them, for nothing is more prejudicial to auriculas in winter than wet; nor must they be too much exposed to the sun in the spring, which is apt to forward their flowering too soon, when the frosts in March are too apt to damage the pips, unless carefully protected. To prevent this, those who are curious place their pots of auriculas under a common hot-bed frame, where, in good wea-

ther, the plants may enjoy the free air, by taking off the glasses, and in great rains, snow, or frost, the plants may be screened by covering them: where this method is practised with judgment, the flowers will be much stronger, and the plant will increase faster, than when they are exposed abroad. In the beginning of February, if the weather is mild, the upper part of the earth in the pots should be taken off as low as possible, so as not to disturb the roots, and fill up with fresh earth: this will much contribute towards strengthening the bloom, as also preparing the off-sets for transplanting in April, by causing them to push out new roots. Those plants which have strong single heads always produce the largest trusses of flowers; therefore the off-sets should be taken off so soon as it can conveniently be done with safety to their growing, in order to encourage the mother plants to flower the stronger. The auricula pots should be covered with mats in frosty weather, during the time of their budding for flower, lest the sharp mornings blight them, and prevent their blowing. When the flower stems begin to advance, and the blossom buds grow turgid, they must be protected from heavy rains, which would wash off their white mealy farina, in which a considerable share of their beauty consists; but at the same time observe to keep them as much uncovered as possible, otherwise the stems will be drawn up too weak to support the truss, also frequent waterings should be given, but not to wet the leaves. When the flowers begin to open, the pots should be removed upon a stage built purposely, facing the morning sun, and covered at top; in this position they will appear to much greater advantage, especially when the flowers are judiciously contrasted; in this situation they may remain till their beauty is past, when they must be set abroad in the open air, in order to obtain good seeds. It may be remarked, that an auricula never thrives well, unless the pot is well filled with its roots; therefore the largest plants, as Perry's King George, when at its greatest size, should not have a pot larger than a thirty-two (so called); and others, which grow of a less size, a half-penny pot is sufficient, into which sized pots, according to the growth of the plant, they should be shifted in the latter end of July, or beginning of August, taking, if possible, the advantage of moist weather.

AURICULAR, whatever belongs or relates to the ear. Thus we say, auricular witness, auricular confession, &c. as being done secretly, and as it were in the ear.

AURICULAR Medicines, such as are used in the cure of distempers in the ear. See the article **EAR**.

AURICULARIS Digitus, the little finger, so called, because it is used commonly to pick the ear.

AURIGA, the waggoner, or carter, in astronomy,

AUR

my, a constellation of the northern hemisphere, containing sixty-six stars according to the British catalogue, forty by Hevelius, and twenty-three by Tycho. In this constellation there are two other constellations to be noted, whereof the one consisteth but of one star, which is in the left shoulder of auriga, and is called hircus, or capra, the goat. The other consisteth of two little stars, a little beneath the other, standing in the hand of auriga, this constellation is called haepi, the hids.

Auriga by the Arabians is called *alaiot*, and by the Greeks, *hemochus*, that is, a man holding a bridle in his hand. Eratostenes affirmeth him to be Eriethonius king of Athens, the son of Vulcan, who having deformed feet, first devised the use of the waggon or chariot, and joined horses together to draw the same, so that sitting therein he might the better conceal his deformity: for which invention, Jupiter translated him into heaven.

The fabulous story concerning the other two constellations is this: Saturn being told by the oracle, that one of his sons should expel him his kingdom, determined to destroy them all. But Ops by stealth conveyed away Jupiter, and sent him to Melifius king of Crete, who had two daughters, Amalthea and Meliffa, to whose care Jupiter was committed. Amalthea had a goat, that gave suck to two kids, so that by the milk of this goat she nourished Jupiter; therefore, to requite this her favour, when he came to his kingdom, he translated the goat and two kids into heaven, in remembrance of his nurse.

Novidus saith, that when Christ was born, and his birth made manifest by the angels unto the shepherds, one of them brought with him a present of a goat and two kids, which in token of his good-will were placed in heaven.

The right ascension, distance from the pole, &c. to the year 1770, will be found in the following Catalogue.

AURIPIGMENTUM, ORPIMENT, in natural history. See **ORPIMENT**.

AURIS, the **EAR**, in anatomy. See **EAR**.

AURISCALPIUM, an instrument to clean the ears, and serving also for any other operation in disorders of that part.

AURORA, the morning twilight, or that faint light which appears in the morning, when the sun is within eighteen degrees of the horizon.

AURORA, the goddess of the morning, according to the pagan mythology. She was the daughter of Hyperion and Theia, according to Hesiod; but of Titan and Terra, according to others. It was under this name that the ancients deified the light, which foreruns the rising of the sun above our hemisphere. The poets represent her as rising out of the ocean, in a chariot, with rosy fingers dropping gentle dew. Virgil describes her ascending in a flame-coloured chariot with four horses.

AURORA Borealis, the northern dawn or light; a remarkable meteor of a luminous appearance, often visible during the night in the northern parts of the heavens.

This meteor exhibits a great variety of phenomena, of which the following are the principal.

1. In the northern part of the horizon there is commonly the appearance of a very black cloud; we say appearance, because it is evidently no real cloud, the smallest stars being visible through it. This apparent cloud is extended sometimes farther towards the west than towards the east; sometimes farther towards the east than towards the west; and generally takes up about a quarter of the horizon.

2. The upper edge of this cloud is generally terminated by a very lucid arch, from one to four or five degrees broad, whose center is below the horizon. Sometimes there are two or more of these arches, one above another. In some the cloud is not terminated by an arch, but by a long streak of light lying parallel to the horizon. The limb of this luminous arch, or parallel streak, is not always even and regular, but sinks lower in some parts than in others.

3. Out of this arch proceed streams of light, generally perpendicular to the horizon, but sometimes a little inclined to it. Most of them seem to end in a point, like pyramids or cones, and often very much resemble the tails of comets. Sometimes there is no luminous arch, nor streak of light; and then the streams seem to issue out from behind the dark cloud, being distinct from each other at their bases.

4. The upper ends of the streams incessantly appear and vanish again, as quick as if a curtain were drawn backwards and forwards before them;

which sometimes causes such a seeming trembling in the air, that the upper part of the heavens were, if we may be allowed the expression, in convulsions.

5. They sometimes seem to meet in the zenith, or more commonly about ten degrees to the southward of it, and there curling round, they, in some measure, imitate flame confined under an arch; and, being frequently tinged with various colours, exhibit a most beautiful appearance, resembling a canopy finely painted, of about ten or twenty degrees in breadth.

In many auroras there are streams ascending from these parts of the heavens, which lie several degrees to the southward of the canopy; and in some they appear to arise, though very rarely, almost as large and numerous from the southern as from the northern parts of the horizon.

6. The height of the aurora borealis is very great; for that on the sixth of March 1715, was visible from the west side of Ireland, to the confines of Russia and Poland to the east; and perhaps much further; extending at least over thirty degrees of longitude, and in latitude from about the fiftieth degree over almost all the north of Europe, and exhibiting, nearly at the same time, the same appearances at all places.

7. These phenomena have always been very frequent in countries near the frigid zone; but very rare in our latitude. They are now however become very frequent with us, but always seem to proceed from the north; and are as yet unknown to the inhabitants of the more southern parts of our hemisphere. Whether they are known to those who inhabit the southern frigid zone, is yet undetermined.

8. In some there are trains of light running horizontally, sometimes from the middle of the extremes, and sometimes with one extreme to another; and from these trains streams perpendicular to the horizon often arise, and accompany them as they pass along.

9. When all the streaming is over, the aurora borealis commonly degenerates into a bright twilight in the north, and there gradually dies away.

10. It is probable these phenomena often happen in cloudy nights, though we are not sensible of them; for it is observable, that in such nights there is frequently more light than what usually proceeds from the stars alone.

The most obvious solution of the aurora borealis, or at least what would appear so to those who have only attended to the circumstances of some particular meteors of this kind, is, that it is a thin nitrosulphureous vapour, raised in our atmosphere, considerably higher than the clouds; that this vapour, by fermentation, takes fire, and the explosions of one portion of it kindling the next, the flashes succeed

ceed one another, till the whole quantity of vapour within their reach is set on fire.

Some have thought that vapours rarefied exceedingly by subterraneous fire, and tinged with sulphureous steams, might thence be disposed to shine in the night, and rising up to the top of the atmosphere, or even beyond its limits, might produce those undulations in the air, which constitute this phenomenon. But these hypotheses have been rejected, as insufficient; it having been thought impossible to account for all the circumstances from them.

Dr. Halley therefore thought proper to have recourse to the magnetic effluvia of the earth, which he supposes to perform the same kind of circulation with regard to it, as the effluvia of any particular terrella do with respect to that, viz. that they enter the earth near the south pole, and, pervading its pores, pass out again at the same distance from the northern: and thinks, they may sometimes, by the concurrence of several causes, very rarely coincident, and to us as yet unknown, be capable of producing a small degree of light, either from the greater density of the matter, or perhaps from the greater velocity of its motion; after the same manner as we see electrical bodies emit light in the dark.

M. de Mairan has given us a physical and historical treatise on the *aurora borealis*, and endeavours to prove, that it is owing to the zodiacal light, or the atmosphere of the sun, spread on each side of it along the zodiac, in the form of a pyramid. This he says is sometimes extended to such a length as to reach beyond the orbit of our earth, and then by mixing itself with our atmosphere, and being of a heterogeneous nature, produces the several appearances observable in the *aurora borealis*.

We thought proper to mention these solutions, because they come from two very ingenious philosophers; though they are certainly too fine-spun to hold, and seem no other than the ingenious reveries of persons determined to frame an hypothesis at any rate. We may certainly find materials for the *aurora borealis*, without having recourse either to the magnetical effluvia of the earth, or the zodiacal light, the nature of both which we are wholly unacquainted with. The effluvia continually exhaled from the surface of the earth, if rightly considered, will afford a very easy and natural solution, as we shall now endeavour to shew.

First, We know from experiment, that there are some steams, as inflammable sulphureous ones, which are capable of so great a degree of expansion, that they will render themselves lighter than the air they float in; even when that fluid is as rare as it can be rendered by art; for they will rise to the top of an exhausted receiver: such steams, or exhalations, therefore, issuing from mines, volcanoes, &c. in the bowels of the earth, must necessarily ascend towards the top of the atmosphere,

at least till they come to a region where the air is as rare and as much expanded as it can be made by the air-pump here below. This height, according to Dr. Halley's computation, founded on the refraction of a ray of light, is forty-four miles and a half (see *ATMOSPHERE*): but may probably be much greater; for the air is higher than any vapours capable of refracting a ray of light can ascend.

Secondly, These effluvia being raised to the top of the atmosphere, or near it, and floating there, will necessarily be carried towards the polar regions for the following reasons. 1. Because the superior current of the air, at a great distance from the equator, tends that way. 2. We know from experiment that whatever swims upon a fluid, which revolves about an axis, is by that very motion carried towards the extremities of that axis. This is exactly the case of these effluvia; for they float near the top of the atmosphere, which continually revolves about the axis of the earth; and must therefore be necessarily carried towards the polar regions. 3. These effluvia being collected together, at or near the poles, and of an inflammable nature, may easily be supposed to ferment, when they meet with other heterogeneous particles proper for producing such an effect, and emit fiery streams, which will naturally rise into such parts of the atmosphere as are still lighter than that in which these corpuscles naturally floated; that is, directly upwards from the center of the earth: but, according to the rules of perspective, these streams, though they really diverge as radii from a center, will appear to a spectator on the surface of the earth to converge towards a point; which point will seem to be directly over his head, if the streams ascend in right lines from the center of the earth; but if they deviate all one way from that direction, the point will be on that side the zenith towards which they incline. To illustrate this, let us suppose several strings to hang down from the ceiling of a room, and a candle to be placed on a table below them: the shadows of these threads will all converge towards the point on the ceiling immediately over the candle: and if they are made to incline from a perpendicular direction, suppose all one way, the point of convergency will remove from the spot immediately over the candle, towards that side of the room to which the upper ends of the strings incline. Now, if a person had viewed them from the place where the candle was set, and referred their places to the ceiling, they would have appeared to have converged towards the same point to which their shadows were directed by the candle.

And if the streams spread themselves as they rise, but not too much, they will still appear tapering towards their upper-ends, like cones or pyramids; just as the sides of a long walk seem to a

person viewing it from one end, to approach each other at the farthest extremity.

Hence every phenomenon of the aurora borealis may be easily accounted for; and its height may be calculated in the following manner:

Let the sine of the elevation of the pole be $=q$, the sine of the greatest altitude of the lucid arch $=m$, the sine of half the distance of the legs of the arch from each other, at the horizon $=g$; the semi-diameter of the earth $=a$, and the sine of the angle which is equal to the greatest altitude of the arch, and the altitude of the equator taken together be $=b$; thus the distance of the matter in the vertex of the arch, from an observer, will be

$$\frac{2amq^2g^2}{r^3b^2 - r^2g^2}.$$

AURUM, GOLD, in natural history; see the article GOLD.

The Latin term, *aurum*, is chiefly used to denote certain chemical preparations, whereof gold is the principal ingredient.

AURUM *Fulminans*, a chemical composition prepared by dissolving gold in aqua regia, and precipitating the metal from the menstruum, by adding a volatile alkali: after which the precipitated powder is educulated by frequent effusions of warm water, and then dried in the shade.

The aurum fulminans, prepared in this manner, weighs about one fourth part more than the gold employed, three parts of gold yielding four of the fulminating powder, according to Lemery, Kunkel, and other practical writers. Part of the increase proceeds from the volatile alkali; for, on adding to the aurum fulminans a little vitriolic acid, the volatile salt rises in sublimation, fatiated with the acid: the remaining powder is found to be divested of its fulminating power. From the co-alition of the volatile alkali with the nitrous acid in the menstruum results an ammoniacal nitre, a salt which of itself detonates on being heated; but by what power or mechanism its detonating quality is so remarkably increased in the aurum fulminans, is unknown.

The explosion of aurum fulminans is more vehement than of any other known kind of matter: it goes off in a less degree of heat than any of the other explosive compositions; and even grinding it somewhat smartly in a mortar, is sufficient for making it explode. Some instances are mentioned in the Bressau Collections, and the Ephemerides Naturæ Curiosorum, of a very small quantity bursting in pieces the marble mortar in which it was rubbed; and an accident of the same kind happened some years ago to a skilful chemist here. The operator cannot therefore be too much on his guard in the management of so dangerous a preparation.

It has been reckoned, that a few grains of aurum fulminans act with as much force as several ounces of gun-powder: but the actions of the two

are of so different kinds, that it is difficult to determine in what manner their strength can be compared. The report of aurum fulminans is of extreme acuteness, offending the ear far more than that of a much larger quantity of gun-powder; but does not extend to so great a distance, seeming to differ from it as the sound of a short or tenfold musical string, from that of a long one, or of one which is less stretched. In some experiments made before the Royal Society, and mentioned in the first volume of Dr. Birch's history, aurum fulminans closed up in a strong hollow iron ball, and heated in the fire, did not appear to explode at all; while gun-powder, treated in the same manner, burst the ball. On the other hand, a little aurum fulminans, exploded on a metalline plate in the open air, makes an impression or perforation in the plate; an effect which gunpowder could scarcely produce in any quantity.

This remarkable effect of aurum fulminans on the body, which serves for its support, has induced some to believe that its action is exerted chiefly or solely downwards. It appears, however, to act in all directions: for a weight laid upon it, either receives a like impression, or is thrown off: and, in the collection abovementioned, an account is given of a large quantity (some ounces) which, exploding from too great heat used in the drying of it, broke open the doors, and shattered the windows in pieces. Mr. Hellot found, that when a few grains of the powder were placed between two leaves of paper, and cemented to one of them by gum water, only the leaf which touched the powder was torn by the explosion, and the other swelled out; and that when both were brought into close contact with it, by pressing them together, it tore them both; from whence he concludes, that the action of the aurum is greatest on the bodies which it immediately touches. Both this property, and the acuteness of the report, may possibly depend upon one cause, the celerity of the expansion: experiments have shewn, that the resistance of the air, to bodies in motion, increases with the velocity of the body in a very high ratio; and perhaps the velocity with which aurum fulminans explodes, may be so great, that it is resisted by the air as by a solid mass. *Lewis's Commercium Philosophico-Technicum.*

AURUM *Masivum*, or *Mosaicum*, a chemical preparation used by japanners in gilding their vessels: it is made in the following manner:

Take of tin, one pound, of flowers of sulphur seven ounces, of sal ammoniacum and purified quicksilver, each half a pound. Melt the tin, and add the quicksilver to it in that state; and when the mixture is become cold, powder it, and grind it with the sal ammoniacum and sulphur, till the whole be thoroughly commixt. Calcine them in a matraass; and the other ingredients subliming,

the tin will be converted into the aurum mofaicum, and will be found in the bottom of the glafs like a mafs of bright flaky gold powder: but if any black or difcoloured parts appear in it, they muft be carefully picked or cut out.

The fal ammoniacum employed, ought to be perfectly white and clean; and care fhould be taken, that the quickfilver be not fuch as is unadulterate with lead, which may be known by putting a fmall quantity in a crucible, into the fire, and obferving when it is taken out, whether it be wholly fublimed away, or have left any lead behind it. The calcination may be beft performed in a coated glafs body, hung in the naked fire; and the body fhould be of a long figure, that the other ingredients may rife fo as to leave the coloured tin clear of them. The quickfilver, though it be formed into cinnabar along with the fulphur, need not be wafed; but may be revived by diftilling it with the addition of quick-lime.

AURUM Potabile, or tincture of gold, a medicine formerly of great request, but at prefent rarely if ever ufed. It is prepared by mixing effential oil of rofemary with a folution of gold in aqua-regia; and, after fhaking the veflel, the gold will be retained in the oil, fwimming on the top. This oil is feparated by inclination, and afterwards digefted for a month in highly rectified fpirit of wine.

But, after all, this is not a genuine tincture of gold, being only the gold divided into very fmall parts by the fpicula of the aqua-regia, fwimming in the oil of rofemary; nor can there be any radical tincture of gold, which may not, by evaporating the oil, be reduced to a powder, and the powder by melting reduced into gold. The virtues of this tincture are entirely owing to the oil of rofemary.

AUSPICIUM. See **AUGURY**.

AUSTERE, rough, aftringent. Thus an auftere tafte is fuch a one as conffrings the mouth and tongue with fome aufterity; as the tafte of unripe fruit.

Things of an auftere tafte are fuppofed by fome, from their glutinous quality, to generate the ftone.

AUSTERITY, among moral writers, implies feverity and rigour. Thus we fay, aufterity of manners.

Aufterity of bodies, according to the Cartefians, confifts in having obtufe angular particles, like a blunt faw.

AUSTRAL, the fame as fouthern; thus auftreal figns are the fix laft figns of the zodiac, being called thus, becaufe they are of the fouthern fide of the equinoctial.

AUTER DROIT, in law, is when perfons fue, or are fued in another's right, as executors, guardians, &c.

AUTER FOIS ACQUIT, in law, a plea made by a criminal that he has been already acquitted of the fame crime, with which he is charged. There are likewife pleas of auter fois convicted and attainat, that he has been before convicted of the fame felony.

AUTHENTIC, fomething of acknowledged and received authority. In law it fignifies fomething clothed in all its formalities, and attested by perfons to whom credit has been regularly given. Thus we fay, authentic papers, authentic inftruments.

AUTHOR, properly fignifies one who created or produced any thing. Thus God, by way of eminence, is called the author of nature, the author of the univerfe.

The word author is fometimes employed in the fame fenfe as inventor. As, Otho de Guerick is reported to be the author of the air-pump.

AUTHOR, in matters of literature, a perfon who has compofed fome book or writing.

Authors may be diftinguifhed into f acred and profane, ancient and modern, known and anonymous, Greek, Latin, Englifh, French, &c. and with regard to the fubjects they treat, into divines, philofophers, orators, hiftorians, poets, grammarians, phyfiologists, &c. See the articles **SACRED**, **PROFANE**, &c.

An original author is he, who, in treating any fubject, does not follow any other perfon, or imitate any model, either in the matter or method of his compofition: for inftance, M. de Fontenelle is an original author in his Plurality of Worlds, but not in his Dialogues of the Dead.

AUTHORITY, in a general fenfe, fignifies a right to command, and make one's felf obeyed. In which fenfe, we fay, the royal authority, the epifcopal authority, the authority of a father, &c.

Authority denotes alfo the testimony of an author, fome apophthegm, or fentence of an eminent perfon, quoted in a difcourfe by way of proof.

AUTHORITY, in law, fignifies a power given by word, or writing, to a fecond perfon to act fomething, and may be by writ, warrant, commiffion, letter of attorney, &c. and fometimes by law. An authority given to another, to do what a perfon himfelf cannot do is void, and it muft be for doing a thing that is lawful, otherwife it will be no good authority.

AUTHORITY is reprefented, in painting, like a grave matron fitting in a chair of ftate, richly clothed in a garment embroidered with gold, holding in her right hand a fword, and in her left a fceptre. By her fide is a double trophy of books and arms.

AUTO DA FE, act of faith. The ceremony of putting in execution the feveral fentences pronounced.

nounced on criminals by the tribunal of the inquisition. It is so called, because it is considered, in those countries where that tremendous court is settled, as the most illustrious and public proof that can be given of a zeal for religion and the Catholic faith. See **INQUISITION**.

AUTOCEPHALOUS, *αυτοκεφαλοι*, in church history, denotes archbishops who were independent of any patriarch.

AUTOGRAPH, *αυτογραφον*, denotes a person's hand-writing, or the original manuscript of any book, &c.

AUTOMATA are mechanical, or mathematical instruments, that, going by springs, weights, &c. seem to move themselves, as a watch, clock, &c.

AUTUMN, the third season of the year, when the harvest and fruits are gathered in. Hence, in the language of the Alchemists, it signifies the time when the philosophers stone is brought to perfection.

AUTUMN is represented, in painting, by a man at perfect age, clothed like the vernal, and likewise girded with a starry girdle; holding in one hand a pair of scales equally poised, with a globe in each; in the other, a bunch of divers fruits and grapes. His age denotes the perfection of this season, and the ballance, that sign of the zodiac which the sun enters when our autumn begins.

AUTUMNAL, something relating to autumn. Thus,

AUTUMNAL Point is that point of the equinox from which the sun begins to descend towards the south-pole.

AUTUMNAL Signs, in astronomy, are the signs *Libra*, *Scorpio*, and *Sagittarius*, through which the sun passes during the autumn. See **ZODIAC**, **LIBRA**, &c.

AUTUMNAL Equinox, the time when the sun enters the autumnal point. See **EQUINOX**.

AUTUMNAL Flowers. See **FLOWER**.

AUX, the same with **apogum**.

AUX also denoted the arch of the ecliptic, intercepted between the first degree of *Aries* and the apogum.

AUXILIARY, *Auxiliaris*, whatever is aiding or helping to another.

AUXILIARY Verbs, in grammar, are such as help to form or conjugate others; that is, are prefixed to them, to form or denote the moods or tenses thereof. As *to have* and *to be*, in the English; *être & avoir*, in the French; *ha & sono*, in the Italian, &c.

In the English language, the auxiliary verb *am*, supplies the want of passive verbs. See **PASSIVE**.

AUXILIUM, in law, the same with aid. See **AID**.

AUXILIUM Curia, in law, a precept or order of court, to cite or convene one party at the suit of another.

AUXILIUM ad filium militem faciendum, vel filiam maritandum, a precept, or writ directed to the sheriff of every county where the king, or other lords, had any tenants, to levy of them reasonable aid towards the knighting his eldest son, or the marriage of his eldest daughter. See the article **AID**.

AWARD, in law, the judgment of an arbitrator, or of one who is not appointed by the law a judge, but chosen by the parties themselves for terminating their difference. See **ARBITRATOR**.

A-WEATHER, in the marine, the opposite term to *a-lee*. See the article **A-LEE**.

A-WEIGH, in the marine, the anchor is called *a-weigh*, or *a-trip*, when the cable, being drawn perpendicularly over it, and continued to be heaved into the ship, at length weighs or trips it out of the ground.

AWL, or **AUL**, among shoe-makers, an instrument wherewith holes are bored through the leather, to facilitate the stitching, or sewing the same. The blade of the awl is usually a little flat and bended, and the point ground to an acute angle.

AWME, or **AUME**, a Dutch liquid measure, containing eight *steckans*, or twenty *verges* or *vertees*, equal to the tierce in England, or to one sixth of a ton of France.

AWN, *arista*, in botany. See **ARISTA**.

AWNING, in the marine, a canopy of canvas extended over the decks in hot weather, to protect them from being split by the heat of the sun; likewise for the convenience of the officers, &c. An awning is supported by a range of wooden pillars, called *stanchions*, erected perpendicularly with the ship's side, on each side of the deck, and suspended in the middle by crowfeet. See the article **CROWFOOT**.

AX, or **AXE**, the same with *axis*.

AX, among carpenters, an instrument wherewith to hew wood.

This implement differs from the joiners hatchet, as being deeper and heavier.

AXILLA, in anatomy, the arm-pit, or the cavity under the upper part of the arm.

AXILLA, in botany, the space comprehended betwixt the stems of plants and their leaves.

AXILLARY, *Axillaris*, something belonging to, or lying near, the axilla. Thus,

AXILLARY Artery is that part of the sub-clavian branches of the ascending trunk of the aorta, which passeth under the arm-pits. See **ARTERY**.

AXILLARY Glands are situated under the arm-pits,

pits, enveloped in fat, and lie close by the axillary vessels.

AXILLARY Vein, one of the subclavian veins which passes under the arm-pit, dividing itself into several branches, which are spread over the arm. See *VEIN*.

AXIOM, in philosophy, is such a plain, self-evident, and received notion, that it cannot be made more plain and evident by demonstration; because it is itself better known than any thing that can be brought to prove it: as, that nothing can act where it is not; that a thing cannot be, and not be, at the same time: that the whole is greater than a part thereof; and that from nothing, nothing can arise.

By axioms, called also maxims, are understood all common notions of the mind, whose evidence is so clear and forcible, that a man cannot deny them, without renouncing common sense and natural reason.

The rule whereby to know an axiom, is this: Whatever proposition expresses the immediate clear comparison of two ideas without the help of a third, is an axiom. But if the truth does not appear from the immediate comparison of two ideas, it is no axiom.

These sort of propositions, under the name of axioms, have, on account of their being self-evident, passed not only for principles of science, but have been supposed innate, and thought to be the foundation of all our other knowledge, though, in truth, they are no more than identic propositions: for to say that all right angles are equal to each other, is no more than saying, that all right angles are right angles, such equality being implied in the very definition. All consideration of these maxims, therefore, can add nothing to the evidence or certainty of our knowledge of them; and how little they influence the rest of our knowledge, how far they are from being the foundation of it, as well as of the truths first known to the mind, Mr. Locke, and some others, have undeniably proved.

According to Bacon, it is impossible that axioms, raised by augmentation, should be useful in discovering new truths; because the subtlety of nature far exceeds the subtlety of arguments: but axioms, duly and methodically drawn from particulars, will again easily point out new particulars, and so render the sciences active.

The axioms in use being derived from slender experience, and in a few obvious particulars, are generally applied in a corresponding manner. No wonder, therefore, they lead us to few particulars; and if any instance unobserved before, happen to turn up, the axiom is preserved by some trifling distinction, where it ought rather to be corrected.

AXIOM is also an established principle in some art or science.

Thus it is an established axiom in physics, that nature does nothing in vain: so it is in geometry, that if to equal things you add equals, the sums will be equal. It is an axiom in optics, that the angle of incidence is equal to the angle of reflection; &c. In which sense too, the general laws of motion are called axioms: whence it may be observed, that these particular axioms are but deductions from certain hypotheses.

AXIS properly signifies that straight line in any plain figure at rest, about which the motion is performed, or the figure revolves, in order to produce, or generate a solid.

Axis, in architecture, is a line in the Ionic capital, passing perpendicularly through the middle of the eye of the volute. See *VOLUTE*.

Spiral Axis, in architecture, is the axis of a twisted column drawn spirally, in order to trace the circumvolutions without. See *COLUMN*.

Axis, in astronomy; first, the axis of the world is a right line, conceived to pass through the center of the earth from one pole of the world to the other; this line is represented by the line 90, 90, Plate IV. fig. 6. in the armillary sphere, drawn from the arctic pole to the antarctic, through the earth in the center. About this line as an axis, the sphere in the Ptolemaic system is supposed to move or make its diurnal revolution.

Axis of a Planet, is that line drawn through its center, about which the planet revolves. The sun, together with all the planets, except Mercury and Saturn, are known to revolve round their respective axis by observation. The earth's axis during its revolution round the sun, remains always parallel to itself, and is inclined to the plane of the ecliptic, making therewith an angle of $66\frac{1}{2}$ degrees. See *PARALLELISM*, &c.

The axis of the equator, ecliptic, horizon, meridian, &c. are right lines drawn through the centers of those circles, perpendicular to the planes of the said circles.

Axis of a Cone, is a straight line or side about which a right-angled triangle moves, and by its rotation forms the cone. Only a right cone can properly be said to have an axis; for an oblique cone cannot be generated by the motion of a plain figure about a straight line at rest: but because it is plain from the definition, that the axis of a right cone is a straight line, drawn from the center of its base to the vertex; therefore, the writers on conic sections, call likewise that line drawn from the center of the base of an oblique cone to the vertex, the axis of the cone.

Axis of a Conic Section, is a right line dividing the section into two equal parts, and cutting all its ordinates at equal angles. Thus, if the line AB, (Plate XI. fig. 4.) be drawn to cut the ordinates aa and bb at right angles, and divide the section

A X I

into two equal parts, then is AB said to be the axis of the section.

Transverse Axis in an Ellipse, is the right line AP, (Plate XI. fig. 1.) drawn through the center of the ellipse, and is always the longest right line that can be drawn in the ellipse.

Transverse Axis in the Hyperbola, is the right line IT, (Plate XI. fig. 7.) cutting the curves in the point I and T.

Conjugate Axis of an Ellipse, is the line BD, (fig. 1.) drawn through the center C, at right angles, to the transverse axis PA; and in the hyperbola, it is the line MC, (Plate XI. fig. 6.) drawn through the center C, parallel to the ordinate OP.

Axis of a Cylinder, is that line either in an oblique or right cylinder, joining the center of the two bases; or a line about which the parallelogram revolving forms the cylinder:

Axis of a Balance, in mechanics, is that line about which it moves.

Axis of Oscillation, is a right line passing through the center about which a pendulum vibrates, and is parallel to the horizon.

Axis in peritrochio, a machine for raising weights, consisting of a wheel fixed on a cylinder for its axis. Thus, when a power by help of a rope, or any other means, is so applied to the circumference of a wheel, as to cause the said wheel, together with its axis, to turn round, and raise a weight applied to the axle; such a machine is called an axle in the wheel, or axis in peritrochio.

Let the circumference of the wheel be ABe, (Plate XVI. fig. 3.) and that of the axle DEc, each moving round the common center of motion C. Let the weight to be raised be P, and the moving power be M; then will M : P :: DC : CB; or in words thus, As the power is to the weight, so is the semidiameter of the axis to the semidiameter of the wheel; when the weight and power will be in equilibrium. Likewise the velocities of the power and weight will be to one another as the peripheries of the wheel and axle, and these are to one another as their diameters. The use of this machine is to raise weights to a greater height than the lever can do, because the wheel is capable of being turned several times round, which the lever is not, and also to communicate motion from one part of a machine to another, by combining two or more of the axes in peritrochio together: thus Plate XVI. fig. 2. is a representation of a machine thus combined; where W is a weight hanging to the axis GMB; P a weight or power acting at the point F, of the wheel IFK; NEQ the axle of the said wheel, acting on the wheel HCL by teeth, and MBR of the wheel HCL.

Having given the diameter of the said wheels and axles, with the power P to find the weight

A X I

W, that will keep the weight or power P in equilibrio.

R U L E.

The rectangle of the semidiameters of the two wheels, multiplied by the power, and that product divided by the rectangle of the semidiameter of the two axes, gives a quotient equal to the weight required.

If we put $a=DF$, $b=DE$, $c=AC$, $d=AB$, w =weight, and p =power, then we shall have the following theorems for finding the dimension of any one part of the machine, the others being supposed to be known. Thus,

$$\frac{p a c}{b d} = w. \quad 1^{st}.$$

$$\frac{w b d}{a c} = p. \quad 2^{d}.$$

$$\frac{w b d}{p c} = a. \quad 3^{d}.$$

$$\frac{w b d}{p a} = c. \quad 4^{th}.$$

$$\frac{p a c}{w d} = b. \quad 5^{th}.$$

$$\frac{p a c}{w b} = d. \quad 6^{th}.$$

But if we would have the machine to do the most execution in a given time, we diminish the weight w , $\frac{2}{3}$ of itself, and then we shall have it in the greatest perfection possible, with the said dimensions. It must likewise be remembered in practice, that the semidiameter of the rope must be added to the dimensions of the wheel or axle, about which it coils, and likewise that the power should always act in the direction of a tangent to the curve, otherwise its power will be diminished, according as it varies from that direction.

Axis, in optics, is that ray which is perpendicularly on the surface of the eye, and consequently passes through its center.

Axis of a Glass, in optics, is a right line, connecting the middle points of the two opposite surfaces of the glass.

Axis of Incidence, in dioptrics, is a line perpendicular to the refracting surface in the point of incidence, and in the medium through which the ray of incidence passes.

Axis of a Magnet, is a line passing through the middle of a magnet length-wise, in such manner, as that however the magnet be divided, provided the division be made according to a plane wherein such line is found, the loadstone will be divided into two loadstones, and the extremes of such lines are called the poles of the stone.

Axis, in natural history, an animal of the deer kind, common in several parts of Africa. It is without horns; but has a tail reaching down to its hams.

Fig 2
Axis in Peretrochio

Fig 3.
Axis in Peretrochio

Fig 5.
Azimuth Compass

hams. The female is less than the male; but they are both full of red, yellow, and white spots, except the belly, which is entirely white.

AXUNGIA, in a general sense, denotes old lard, or the driest and hardest of any fat in the bodies of animals; but, more properly, it signifies only hog's lard. See the articles **FAT** and **LARD**.

AXUNGIA Vitri, sandiver, or salt of glass, a kind of salt which separates from the glass while it is in fusion.

AYEL, in law, a writ which lies where the grand-father was seized in his demesne the day he died, and a stranger enters the same day, and dispossesses the heir.

AYRY, or **AERY** of *Hawks*, a nest or company of hawks, so called from the old French word *aire*, which signified the same.

AZAB, in the Turkish armies, a distinct body of soldiers, who are great rivals of the Janizaries.

AZALEA, in botany, a genus of pentandrious plants, bearing a monopetalous campanulated flower, received at the summit into five segments; in the receptacle are inserted five slender filaments topped with oblong bifid antheræ; the germen, which is roundish, supports a filiform style, crowned with an obtuse stigma: the fruit is a roundish capsule, formed of five valves, and the same number of cells, containing a number of roundish small seeds.

One of the sorts of azalea has much the appearance of the honey-suckle, and is as agreeably scented; the flower is white, and appears in July, but their seeds do not ripen in England; they are natives of North America, and are propagated here by shoots from their roots, and by laying their branches in autumn.

AZAZEL, the scape-goat, in Jewish antiquity. See **SCAPE-GOAT**.

AZEDARACH, the bead-tree, in botany. See the article **MELIA**.

AZEROLE, or **L'AZEROLE**, in botany, a species of the medlar. See the article **MESPILUS**.

AZIMUTH, in astronomy, is an arc of the horizon comprehended between the meridian and any great circle passing through the zenith and nadir, or the angle at the zenith contained between the said meridian and vertical circle.

The azimuth of the sun, planet, or star, is the angle contained between the meridian and a vertical circle passing through the center of the sun, planet, or star.

The method of finding the sun's azimuth at sea, is by carefully observing his altitude with a Hadley's quadrant, and estimating the latitude of the ship, from the way it has made since the last observation of the meridian, or other altitudes for that purpose;

likewise, by taking the sun's declination from some Ephemerides, or correct tables. From hence we have the three sides of a spherical triangle, to find one of the angles, which is the azimuth required. Thus, $Z \odot$ (Plate XVI. fig. 4.) will be the complement of the altitude; ZP , the complement of the latitude; $\odot P$ the complement of the sun's declination; and $\odot ZP$, the angle or azimuth required; which is found by the following rule, viz.

From half the sum of the three sides, subtract the complement of the sun's declination, or the side opposite the angle sought, and note the remainder; then set down the arithmetical complements of the sine of the complements of altitude and latitude; and place under these the sine of the half sum of the sides, and the sine of the noted difference; then will half the sum of these four logarithms be the cosine of half the azimuth required.

EXAMPLE.

Suppose the latitude in *per* reckoning be 40 degrees north, and the sun's altitude observed 20 degrees, and his declination 20 degrees north, what will his azimuth be?

70° : 0'	Comp. of Decl ⁿ	-	-	-	
50 : 0	Comp. of Lat.	-	-	-	0.1157460
70 : 0	Comp. of Alt.	-	-	-	0.0270142
190 : 0	Sum of the sides				
85 : 0	$\frac{1}{2}$ Sum	-	-	-	9.9983442
15 : 0	Diff. of $\frac{1}{2}$ sum and comp. of declination	-	-	-	9.4129962
	Sum =				19.5541006
53 : 11 +	= sine comp. half Sum =				9.7770503

therefore, $53^{\circ} : 11'$ being doubled gives $106^{\circ} : 22'$ for the sun's azimuth required.

To find the azimuth by the globe. See the article **GLOBE**.

Magnetical AZIMUTH, is an arch of the horizon, intercepted between the azimuth or vertical circle, passing through the center of any heavenly object and the magnetical meridian, which is found by observing the object with an azimuth-compass.

AZIMUTH-COMPASS, an instrument for finding either the magnetical azimuth or amplitude of an heavenly object.

The learned Dr. Knight invented some-time since a very accurate and useful sea-compass, which is at present used in the navy, and will be described under the article **COMPASS**. This instrument, with the following contrivance added by the ingenious Mr. Smeaton, answers the purpose of an azimuth and amplitude-compass.

The cover of the wooden box being taken off, the compass is in a condition to be made use of in the

the binnacle, when the weather is moderate: but if the sea runs high, as the inner box is hung very free upon its centers, (the better to answer its other purposes) it will be necessary to slacken the milled nut, placed upon one of the axes that supports the ring, and to lighten the nut on the outside that corresponds to it. By this means, the inner box and ring will be lifted up from the edges, upon which they rest, when free; and the friction will be increased, and that to any degree necessary, to prevent the too great vibrations, which otherwise would be occasioned by the motion of the ship.

To make the compass useful in taking the magnetic azimuth, or amplitude of the sun and stars, as also the bearings of headlands, ships, and other objects at a distance, the brass edge, designed at first to support the card, and throw the weight thereof as near the circumference as possible, is itself divided into degrees and halves; which may be easily estimated into smaller parts, if necessary. The divisions are determined by means of a cat-gut line, stretched perpendicularly with the box, as near the brass-edge as may be, that the parallax, arising from a different position of the observer, may be as little as possible.

Underneath the card are two small weights, sliding on two wires, placed at right angles to each other, which being moved nearer to, or farther from, the center, counterbalance the dipping of the card in different latitudes, or restore the equilibrium of it, where it happens by any other means to be got too much out of level.

There is also added an index at the top of the inner box, which may be put on and taken off at pleasure; and serves for all altitudes of the object. It consists of a bar, equal in length to the diameter of the inner box, each end being furnished with a perpendicular stile, with a slit parallel to the sides thereof; one of the slits is narrow, to which the eye is applied, and the other is wider, with a small cat-gut stretched up the middle of it, and from thence continued horizontally from the top of one stile to the top of the other. There is also a line drawn along the upper surface of the bar. These four, viz. the narrow slit, the horizontal cat-gut thread, the perpendicular one, and the line on the bar, are in the same plane, which disposes itself perpendicularly to the horizon, when the inner box is at rest, and hangs free. This index does not move round, but is always placed on, so as to answer the same side of the box.

When the sun's azimuth is desired, and his rays are strong enough to cast a shadow, turn about the wooden box, till the shadow of the horizontal thread, or (if the sun be too low) till that of the perpendicular thread, in one stile, or the light through the slit in the other, falls upon the line in the index bar, or vibrates to an equal distance on

each side of it, gently touching the box, if it vibrates too far: observe, at the same time, the degree marked upon the brass edge by the cat-gut line. In counting the degree for the azimuth, or any other angle that is reckoned from the meridian, make use of the outward circle of figures upon the brass edge; and the situation of the index bar, with regard to the card and needle, will always direct upon what quarter of the compass the object is placed.

But if the sun does not shine out sufficiently strong, place the eye behind the narrow slit in one of the stiles, and turn the wooden box about, till some part of the horizontal, or perpendicular thread appears to intersect the center of the sun, or vibrate to an equal distance on each side of it, using smoked glass next the eye, if the sun's light is too strong. In this method, another observer will be generally necessary, to note the degree cut by the nonius, at the same time the first gives notice that the thread appears to split the object.

From what has been said, the other observations will be easily performed; only, in case of the sun's amplitude, take care to number the degree by the help of the inner circle of figures on the card, which are the complements of the outer to 90°; and, consequently, shew the distance from east or west.

The azimuth of the stars may also be observed by night; a proper light serving equally for one observer to see the thread, and the other the degree upon the card.

It may not be amiss to remark farther, that, in case the inner box should lose its equilibrium, and, consequently, the index be cut off the plane of a vertical circle, an accurate observation may still be made, provided the sun's shadow is distinct; for, by observing first with one end of the index towards the sun, and then the other, a mean of the two observations will be the truth.

Plate XVI. fig. 5. is a perspective view of the compass, when in order for observation; the point of view being the center of the card; and the distance of the eye two feet.

AB is the wooden box.

C and D are two milled nuts, by means whereof the axis of the inner box and ring are taken from their edges, on which they move, and the friction increased, when necessary.

EE is the ring that supports the inner box.

GH is the inner box; and

I is one of its axes, by which it is suspended on the ring EE.

The magnet or needle appears passing through the center, together with a small brace of ivory, that confines the cap to its place.

The card is a single varnished paper, reaching

as far as the outer circle of figures, which is a circle of thin brass; the edge whereof is turned down at right angles to the plane of the card, to make it more stiff.

O is a cat-gut line, drawn down the inside of the box, for determining the degree upon the brass edge.

PQRS is the index bar, with its two stiles and cat-gut threads; which being taken off from the top of the box, is placed in two pieces, T and V, watched properly to receive it.

W is a place cut out in the wood, serving as an handle.

AZIMUTH *Dial*, one whose style or gnomon is at right angles to the plane of the horizon.

AZIMUTH *Circles*, commonly called vertical circles, are great circles of the sphere intersecting each other in the zenith and nadir, and cutting the horizon in every point at right angles. These azimuths are represented on the globe by the brass quadrant of altitude, and on the common sea-charts by the rumbs. On the azimuth circles is reckoned the altitude or height of heavenly objects, when not in the meridian.

AZOGA SHIPS, are those Spanish ships commonly called the quicksilver ships, from their carrying quicksilver to the Spanish West-Indies, in order to extract the silver out of the mines of Mexico and Peru. These ships, strictly speaking, are not to carry any goods unless for the king of Spain's account.

AZONI, *αζωνι*, in ancient mythology, a name applied by the Greeks to such of the gods as were deities at large, not appropriated to the worship of any particular town or country, but acknowledged in general by all countries, and worshipped by every nation. These the Latins called *dii communes*. Of this sort were the Sun, Mars, Luna, &c.

AZOTH, in ancient chemistry, the first matter of metals, or the mercury of a metal; more particularly that which they call the mercury of philosophers, which they pretend to draw from all sorts of metallic bodies.

The azoth of Paracelsus, which he boasted of as an universal remedy, is pretended to be a preparation of gold, silver, and mercury.

AZURE, in a general sense, the blue colour of the sky. See SKY and BLUE.

AZURE, among painters, the beautiful blue

colour, with a greenish cast, prepared from the lapis lazuli, generally called ultramarine.

With greater propriety, however, azure signifies that bright blue colour, prepared from the lapis armenus, a different stone from the lapis lazuli, though frequently confounded together. This colour is, by our painters, commonly called Lambert's blue.

AZURE, in heraldry, the blue colour in the arms of any person below the rank of a baron. In the escutcheon of a nobleman, it is called sapphire; and in that of a sovereign prince, Jupiter. In engraving, this colour is expressed by lines, or strokes drawn horizontally.

AZURIUM, the name of a chemical preparation from two parts of mercury, one of sulphur, and a fourth of sal ammoniac, mixed in a mortar, put into a glass vessel, and set over the fire till a bluish smoke arises, &c.

AZYGOS, in anatomy, a vein rising within the thorax on the right side, having no fellow on the left; whence it is called azygos, or vena sine pari.

It is extended through the right side of the cavity of the thorax, and being descended to the eighth or ninth vertebra, it then begins to keep the middle, and sends forth on each side intercostal branches to the interstices of the eight lowest ribs; being then divided into two branches, of which the larger descends to the left, betwixt the processes of the diaphragm, and is inserted sometimes into the cava, above or below the emulgent, but oftener joined to the emulgent itself. The other, which goes down on the right side, enters the cava, commonly a little above the emulgent, but is very seldom joined to the emulgent itself.

AZYMITES, *azymitæ*, in church-history, Christians who administer the eucharist with unleavened bread.

The word is formed from the Greek, *α*, priv. and *ζυμν*, ferment.

This appellation is given to the Latin by the Greek church, because the members of the former use fermented bread in the celebration of the eucharist. They also call the Armenians and Maronites by the same name, and for the same reason.

AZYMOS, something unfermented, or made without leaven; as unleavened bread. Sea-bisket is of this kind; and therefore, according to Galen, less wholesome than bread that has been fermented.

B.

B A C

B, The second letter of the English and most other alphabets, ancient and modern, except the old Irish, where it is the first, and the Abyssinian, in which it is the ninth.

B, among the ancients, was a numeral letter, and with the Hebrews and Greeks denoted 2; but with the Romans 300, and with a dash over it 3000.

B. A. signifies batchelor of arts, B. L. batchelor of laws, and B. D. batchelor of divinity.

BAAL, or BEL, an Hebrew and Chaldaic word, which signifies lord, or mighty. It was the name of the idol of the Moabites and Phœnicians, and most of the nations that bordered upon the Jews. Perhaps the idolators pretended to adore the true God under the name and figure of Baalim. The Grecians, who were accustomed to take the eastern divinities for their own, called this idol Jupiter, and sometimes Mars; but the Babylonians understood by it either the stars and host of heaven, or such kings and heroes whose memory they had consecrated to posterity by a religious worship. The Phœnicians adored the sun under the names of Baal and Moloch. It is thought this idol was first invented by superstition, and the original worship of idolatry. *Selden de Diis Syriis.*

BABBLING, among sportsmen, is said of hounds which are too busy after they have found a good scent.

BABOON, in natural history, a large kind of ape, common in the East and West-Indies. The head is large, and the mouth furnished in a particular manner with whiskers; the face is naked, but the back part of the head hairy. It has a very short tail, and is of a dark olive colour.

BABYLONISH, or BABYLONIAN, something belonging or peculiar to Babylon. Thus we meet with Babylonish epocha, hours, &c. See EPOCH, HOUR, &c.

BACCA, in botany, the Latin appellation for a berry: it implies a round fruit, for the most part

B A C

soft and covered with a thin skin, and contains seeds in a pulpy substance; but if it be harder, or covered with a thicker substance, it may with more propriety be called pomum, or apple. Berries which grow scattered upon trees and shrubs are distinguished from acini, which are berries hanging in clusters. See the article ACINUS.

These berries are of various forms, sizes, properties, and uses, according to the plants on which they grow: some are used in dying, as French berries, a species of the lycium; the most remarkable in the materia medica are, *bacca alkekengi*, *bacca juniperi*, *bacca myrti*, and *bacca agni casti*. See the properties of each under its respective article.

BACCHANALIA, feasts celebrated in honour of Bacchus, by the ancient Greeks and Romans.

Two of these feasts were particularly remarkable, and distinguished by the epithets *greater* and *lesser*. The latter were held in the open fields during the autumn; but the former were celebrated in the city about the vernal equinox.

Both these feasts were accompanied with games, spectacles, and theatrical representations; and it was also at these festivals that the poets contended for the prize of poetry. Some of those who were initiated into the Bacchanalia represented Silenus; others Pan; others Satyrs; and in this manner appeared in public day and night, counterfeiting drunkenness, dancing obscenely, committing all kinds of licentiousness and debauchery, and running over the mountains and through the forests, with horrible shrieks and howlings, crying out, *Εὐοι Βάκχες*, or *Ιὼ Βάκχες*.

Livy informs us, that, during the Bacchanalian feasts at Rome, such shocking disorders were practised under the cover of the night, and which those who were initiated were bound by the most horrid oaths to conceal, that the senate were obliged to interpose their authority, by suppressing them first at Rome, and afterwards throughout all Italy.

BACCHARIS, in botany, a genus of plants whose flower is composed of many hermaphrodite and female florets: the hermaphrodite are quinquefid and funnel-shaped, and contain five small hairy filaments crowned with cylindrical anthers: the germen is ovate, supporting a filiform style; and the calyx (which is cylindrical and imbricated) incloses a short oblong solitary seed crowned with simple down. The female florets have no stamina, but in other respects are the same as the hermaphrodite. There are two species in this genus, one of which is known by the name of African tree groundfel, with a sawed leaf; it is a native of several parts of America, and has been long preserved in England by the curious: the other sort, called the Virginia groundfel tree, is a shrub which grows about seven or eight feet high, and produces here white flowers in October, and the leaves are evergreen. Both sorts may be multiplied, by cuttings, in the summer months.

BACCHIUS, in ancient poetry, a kind of foot composed of two long and a short syllable, as the word *ἀνὰνι*. It has its name from the god Bacchus, because it frequently occurred in the hymns composed in honour of that deity.

BACCHUS, in mythology, a pagan deity, the inventor or god of wine. He is feigned to have been the son of Jupiter and Semele; and is said to have been the first that yoked oxen to the plough.

BACCIFEROUS, (from *Bacca*, a berry, and *fero*, to bear) in botany, are such plants as bear berries.

Mr. Ray divides bacciferous trees into four kinds.

1. Such as bear a calcute, or naked berry, the flower and calyx both falling off together, and leaving the berry bare; as the lassafras, &c.

2. Such as have a naked but polypyreneous fruit; that is, containing two or more kernels or seeds within it; as the jasmine, privet, &c.

3. Such as have a naked polypyreneous fruit; that is, containing in it several seeds; as the arbutus, &c.

4. Such as have their fruit composed of several acini, or soft round balls, set close together like a bunch of grapes; as the honey-suckle, &c.

BACHELOR, or **BACHELOR**. See **BACHELOR**.

BACK, in anatomy; see **DORSUM**.

BACK-ASTERN, in rowing, to ply the oars in such a manner that the boat or vessel shall move stern-foremost, contrary to her usual motion.

BACK-BOARD of a Boat, a piece of board stretching across the hinder-part of any boat, for the passengers to recline against.

BACKING the Sails, in the marine, to dispose them in a situation that will force the ship to retreat, or impel her backwards: this, however, is only done in narrow channels, when a ship is carried along sideways by the tide or current, and wants to

avoid any object that may intercept her progress, as shoals, vessels at anchor, &c. or in the line of battle, when a ship wants to lie immediately opposite to some other with whom she is engaged, or is too far advanced for her station. See **ABACK**; also **FILL**, **SHIVER**, **VEER**.

BACK-BONE. See **VERTEBRA**.

BACK-PAINTING, the method of painting mezzotinto prints, pasted on glass, with oil-colours.

The art consists chiefly in laying the print upon a piece of crown glass, of such a size as fits the print.

In order to do this, take your print and lay it in clean water for two days and two nights, if the print be on very strong, close, and hard gummed paper; but if upon an open, soft, spongy paper, two hours will sometimes suffice, or more, according as the paper is.

The paper or picture having been sufficiently soaked, take it out and lay it upon two sheets of paper, and cover it with two more; and let it lie there a little to suck out the moisture.

In the mean time, take the glass the picture is to be put upon, and set it near the fire to warm; take Straßburg turpentine, warm it over the fire till it is grown fluid; then with a hog's-hair-brush spread the turpentine very smoothly and evenly on the glass.

When this has been done, take the mezzotinto print from between the papers, and lay upon the glass; beginning first at one end, rubbing it down gently as you go on, till it lie close, and there be no wind bladders between.

Then, with your fingers, rub or roll off the paper from the back-side of the print, till it looks black, i. e. till you can see nothing but the print, like a thin film, left upon the glass, and set it by to dry.

When it is dry, varnish it over with some white transparent varnish, that the print may be seen through it, and then it is fit for painting.

The utmost care will be necessary in rubbing or rolling the paper off the print, so as not to tear it, especially in the light parts.

You may, instead of soaking your prints two days and two nights, roll them up and boil them for about two hours, more or less, according to the quality of the paper, in water, and that will render it as fit for rubbing, rolling, or peeling, as the other way.

This being done, and your oil colours prepared, ground very fine, and tempered up very stiff, lay on the back-side of the transparent prints such colours as each particular part requires; letting the master-lines of the prints still guide your pencil, and so each particular colour will lie fair to the eye on the other side of the glass, and look almost as well as a painted piece, if it be done neatly.

The shadows of the print are generally sufficient for the shadow of every colour; but if you have a mind

mind to give a shadow by your pencil, then let the shadows be laid on first, and the other colours afterward.

In laying on colours in this kind of back-painting, you need not be curious as to the laying them on smooth. This is not at all requisite here, where the chief aim is only to have the colours appear well on the fore-side of the print; and therefore the only care to be used in this work, is to lay the colours on thick enough, that its body may strike the colour of it plainly through the glass.

BACK-STAFF, the same with Davis's Quadrant. See *Davis's Quadrant*.

BACK-STAYS, in the marine, ropes that reach from the top-mast-heads down to the outside of the ship, when they are stretched extremely tight: two of them are generally formed of one rope; the middle part of which is fixed on the mast-head: their use is to support the masts, and keep them from bending too much when they are pressed by a load of sail, against the impulse of which they act with a counter-force.

BACON'S *Philosophy*, the philosophy proposed and recommended by lord Bacon.

That great genius was born in the year 1560, and gave marks in his youth of what his manhood would produce. Queen Elizabeth was an admirer of his remarkable sagacity. He studied the Aristotelian philosophy at Cambridge; and, before he was sixteen years of age, discovered the absurdity of that jargon in vogue at that time. He afterwards applied himself to the study of the law; and his merit raised him to the dignity of lord chancellor, under king James I. He was accused of bribery; and, the king refusing him protection, was fined by the house of lords, stripped of his chancellorship, and cast into prison. He was soon after reinstated in his honours and fortunes; but what he had undergone gave him a dislike to business, and increased his passion for study. At last he died aged 66 years, poor, and in very mean circumstances.

No man has contributed more to the advancement of learning than lord-chancellor Bacon: he saw the imperfection of the philosophy of the schools, and taught the only way to amend it. This great man, indeed, did not know nature; but he knew and pointed out all the ways that led to her. He entertained an early contempt for what the universities called philosophy; and did every thing in his power to prevent societies, instituted for the improvement of human reason, from continuing to spoil it by a heap of impertinent terms, substantial forms, &c. which had not only made ignorance to be revered, but was, by a ridiculous mixture with religion, rendered sacred.

He composed two works with a design to improve the sciences, and carry them to perfection. In the first, intitled *de Augmentis Scientiarum*, he shews the state of learning, and points out a method of carry-

ing it to greater perfection; but adds, that we must never hope to carry our discoveries to any great length, unless other methods were pursued than those then in use. He shews that the logic then taught in the schools, was fitter for wrangling than to direct the mind in its search after truth. Aristotle, says he, from whom we have this art, has proceeded on wrong principles; he has made his physics conformable to his logic, instead of making his logic conformable to his physics; and thus overturning the order of nature, has subjected the end to the means.

To correct the faults in the common logic, Bacon composed a second work, intitled *Organum Scientiarum*, wherein he has taught a new logic, the principal end of which is to shew how to make a good induction, as the end of Aristotle is how to make a good syllogism. Bacon looked on this as his master-piece, and spent eighteen years in composing it.

Nor was the cause of our errors hid from this great man; he saw that our ideas were operations of the mind; and that, in order to discover truth, they must be directed in a new method.

This advice he frequently repeats in the work just mentioned. But who, in an age so prejudiced in favour of the jargon of the schools, and the notions of innate ideas, listened to his doctrine? Who did not look on his new method of improving the human understanding, as a chimerical project? The method Bacon proposed was too perfect to be accepted at once: errors of long standing maintain their post with some obstinacy; and the Cartesian philosophy was embraced, because it admitted some of the former errors. Besides, lord Bacon's employment took up much of his time, and prevented him from carrying into execution himself the advice he gave to others: whereas Descartes gave himself up entirely to philosophy; and, being a man of a very lively and fruitful imagination, has substituted in the room of the errors of the schools, others of a more seducing nature.

Lord Bacon's attention to the sciences in general did not hinder him from applying to some in particular; and as he thought natural philosophy the basis of all the other sciences, he principally applied himself to bring that to some degree of perfection: but in this he acted like some great architects, who, scorning to work after others, begin with pulling every thing down, and raise their building on a plan entirely new. He, like these, never thought once about embellishing or repairing what had been already begun by others; but proposed to establish a new system of physics, without making any use of what had been left us by the ancients, whose principles he suspected. To accomplish this great design, he resolved to publish a physical treatise every month; and began with one upon the Winds: he afterwards published one on Heat; another on Motion;

tion; and, at last, one on Life and Death. But as it was impossible for a single man to give a complete system of physics in general, with equal exactness, after having given directions to serve as a rule for those who were desirous of proceeding on his principles, he contented himself with drawing the out-lines of four other treatises, and furnished materials for them, in a work, intitled *Sylva Sylvarum*, wherein he has collected a vast number of experiments, to serve as a foundation for his new physics. In short, before Lord Bacon, nobody knew any thing of natural philosophy; and all the experiments made since his time seem to have been pointed out by this great genius.

His moral essays are much esteemed; but they are wrote rather to instruct than entertain: an easy genius, a sound judgment, the sensible philosopher, and man of reflection, shine in these essays by turns. This was one of the fruits of the retreat of a man who had quitted the world, after having long supported a great share in its prosperity and adversity. There are also some very fine things in his book concerning the wisdom of the ancients, wherein he has moralized the fables which compose the mythology of the Greeks and Romans.

He wrote, besides, the History of Henry VII. in which, notwithstanding there are some traces of the bad taste of his age, yet it abounds in judicious remarks, and shews he was a refined politician, as well as a great philosopher.

BACULÆ, in fortification, a kind of portecullis, or gate, made like a pitfall with a counterpoise, and supported by two strong stakes. It is usually erected before the corps de gard, not far from the gate of a place.

BACULOMETRY, according to some, is the art of measuring accessible or inaccessible heights, by the help of staves.

The word is formed from the Latin, *baculus*, a staff; and the Greek, *μετρα*, to measure.

BADGE, in naval architecture, an ornament placed on the outside, very near the stern of small ships, containing either a window for the convenience of the cabin, or the representation of it: it is commonly decorated with marine figures, martial instruments, &c. &c. See **STERN**.

BADGER, *Taxus*, or *Moles*, in natural history, the name of an animal very common in many parts of England.

It has a thick shortish body, with a very short neck, and coarse hair, nearly resembling that of a hog. On the back it is of a palish yellow at the roots, in the middle brown or black, and yellow at the ends; inasmuch that at first sight the creature appears to be of a blackish grey. On the sides and under the belly the hair is entirely of a pale yellow; and on the shoulders, legs, as well before as behind, and under the throat, he is quite black. From the top of the head there is a white line or stripe two

inches broad; and below it, on each side the nostrils, about the eyes, and farther than the ears, there is a black space or stripe in the shape of a pyramid; and below that again, on both jaws, the hair is white, which render the whole head of a pied colour.

The tail is short and thick, beset with strong longish hair, and the ears are short, roundish, and resemble those of a rat. The eyes are small in proportion to the body, and the muzzle is like that of a dog. The tongue is of a middle size, the legs short, and the teeth like those of a dog. The fore-feet are armed with very long claws, with which it makes holes in the earth; and the head is in shape nearly like that of a fox; for from a broad base, it ends in a sharp muzzle, which renders it almost of a triangular figure. The jaws, or cheeks, are full and tumid, on account of the thickness of the muscles; for which reason this creature bites very hard.

He lives upon beetles and other insects; for in his stomach, which is very large, great numbers of these have been found, mixed with the roots of grass. Some say he feeds upon apples and grapes; and that he is fond of rabbits, geese, fowls, and other birds; but, of this, little can be said with any certainty. He has none of the gross intestines; nor no blind gut, at least none could be found; but the kidneys are pretty large. The greatest peculiarity is a large orifice directly under the tail, above the passage for the excrements: it is a sort of a bag, or purse, which is hairy within, and full of a white substance of a thick consistence. Sometimes it is very small in quantity, and has no sensible smell. The external part of this purse is covered with conglomerate glands on all sides. Besides this cavity, there are two larger glands near the anus, which are hollow within, and full of a sort of fat of a strong smell, which empty themselves by two holes into the gut. The gall-bladder is long; and there are three biliary ducts which belong to three distinct vessels; that is, there are three biliary passages that concur with the cystic duct.

The burrows that he makes in the earth are not only for his own safety, but for the sake of getting his food; for he finds a great many insects under the earth, as well as the roots of plants. The parts of England in which he chiefly abounds at present, are Essex, Sussex, and some of the midland counties.

The flesh of a badger is said to be good eating, and to taste like that of a boar. The fat is emollient, warm, and penetrating; and is thought to be good to ease pains in fits of the gravel.

White BADGER, an animal sometimes seen in New-York; from the tip of the nose to the end of the tail is a foot and nine inches in length. The eyes are small in proportion to the size, and the ears short; the legs are also very short, with white claws. The whole body is covered with very thick

B A F

hair, which is white on the back, and of a whitish yellow on the lower parts.

The badger of Surinam is about a foot and a half long, with short ears, a roundish head, longish muzzle, and short legs. The claws are black, long, and crooked: and the whole body, except the belly which is yellow, is covered with hair of a deep chestnut colour inclining to black; but the fore-part of the head is not of so deep a colour; and the tail, which is as long as the body, is brown, and as it were striped with yellow.

BADGER, in old law books, a person licensed to purchase corn at one place, and sell it at another, without incurring the penalty of an engrosser.

BADIANE, or BADIAN, the seed of a tree growing in China. It has the smell of aniseed; and is used by the Chinese to give their tea an aromatic taste.

BÆCKEA, in botany, a genus of oestrandrous plants, producing a flower with a monophyllous funnel-shaped calyx, in which is inserted five roundish petals; it contains eight short filaments, topped with small egg-shaped antheræ; the germs are roundish, supporting a filiform style, and afterwards becomes a globose capsule of five cells containing roundish seeds.

BÆTYLIA, anointed stones, worshipped by the Phœnicians. They were commonly of a black colour, and consecrated to some god, as Saturn, Jupiter, the Sun, &c.

The memory of Jacob's setting up the stone he had used for a pillow, pouring oil on the top of it, and calling the place Bethel, seems to have been preserved under the bætylia, or anointed stones, of the Phœnicians. Damascius, a pagan writer in the time of Justinian, tells us, that he had seen on Mount Libanus, near Heliopolis in Syria, several of these stones, of which many wonderful things were reported.

BAFFETAS, or BASTAS, a cloth made in the East-Indies, from coarse white cotton thread. Those of Surat are reckoned the best. They are from thirteen French ells and three quarters to fourteen long, and seven eighths broad. There are also some which measure but five sixths of an ell, or even but half of an ell in breadth. These narrow baffetas are called Orgagis, Gaudivis, Nerindes, and Labouis, according to the names of the places where manufactured.

There are also narrow white baffetas, which measure thirteen ells and an half in length; by half an ell in breadth; broad white baffetas, fourteen ells by three quarters.

Broad-brown and narrow-brown baffetas are made of raw thread; that is, thread before it has been bleached. The former are fourteen ells long, by half an ell broad; the latter of the same length, and three quarters in breadth.

B A G

BAG, in commerce, a term signifying a certain quantity of some particular commodity; as a bag of almonds, for instance, is about three hundred weight; of aniseeds, from three to four hundred, &c.

Bags are used, in most countries, to put several sorts of coin in, either of gold, silver, brass, or copper. Bankers, and others, who deal much in current cash, label their bags of money, by tying a ticket or note at the mouth of the bag, signifying the coin therein contained, the sum total, its weight, and of whom it was received. Tare is allowed for the bag.

BAG, among farriers, is when, in order to retrieve a horse's lost appetite, they put an ounce of assa-fœtida, and as much powder of favin, into a bag, to be tied to the bit, keeping him bridled for two hours, several times a day: as soon as the bag is taken off, he will immediately eat. The same bag will serve a long time.

BAGGAGE, is particularly used, in the military art, for the necessaries, utensils, apparel, &c. of the officers and soldiers.

The baggage includes also women, children, sutlers, &c. The baggage-waggons before a march are appointed a rendezvous, where they are marshalled by the waggon-master general, according to the rank the several regiments bear in the army. On a march, they are sometimes ordered to follow the respective columns of the army, sometimes to follow the march of the artillery, and sometimes to make a column of themselves. The general's baggage is commonly first. If the army march from the right, the baggage of that wing has the van; if from the left, the baggage of the left has the van. Each waggon has a distinguishing flag, to shew to what regiment it belongs. Guillet.

BAGNIO, an Italian word, signifying a bath: we use it for a house with conveniences for bathing, cupping, sweating, and otherwise cleansing the body; and sometimes for worse purposes.

BAGNIO is, in Turkey, become a general name for the prisons where their slaves are inclosed, it being usual in these prisons to have baths.

BAGNOLIANS, *Bagnolenses*, in church-history, a sect of heretics, who in reality were Manichees, though they somewhat disguised their errors. They rejected the Old Testament, and part of the New; held the world to be eternal, and affirmed that God did not create the soul when he infused it into the body.

BAGPIPE, a musical instrument of the wind kind, chiefly used in country places, especially in the North: it consists of two principal parts; the first a leathern bag, which blows up like a football, by means of a port-vent, or little tube, fitted to it, and stopped by a valve: the other part consists of three pipes or flutes, the first called the

great

great pipe, or drone; and the second, the little one; which pass the wind out only at the bottom: the third has a reed, and is played on by compressing the bag under the arm, when full, and opening or stopping the holes, which are eight, with the fingers. The little pipe is ordinarily a foot long; that played on, thirteen inches; and the port-vent fix.

BAHAR, or BARR, a weight used in Ternate, Mocha, in the Moluccas, Achem, and divers other parts of the East-Indies.

There are two kinds, the great, wherewith spice is weighed, equivalent to 200 cati, at 26 taels to the cati, amounting to 481 pounds 4 ounces, Paris measure.

The little bahar serves for the weighing quicksilver, vermilion, ivory, silk, musk, and other precious wares, containing likewise 200 cati, but at 22 taels to the cati, amounting to about 401 pounds seven ounces, Paris measure. The Chinese bahar is 300 cati, but each cati only equal to 16 taels.

BAHIR, a Hebrew term, signifying famous or illustrious; but particularly used for a book of the Jews, treating of the profound mysteries of the cabala, being the most ancient of the rabbinical works.

BAIL, in law, the setting at liberty one arrested, or imprisoned, upon an action, either civil or criminal, upon sureties taken for his appearance at a day and place assigned; and is either common or special.

Common bail is in actions of small prejudice, or slight proof, in which case any sureties are taken.

Special bail is that given in cases of greater moment, where it is required that the sureties be subsidy-men at least, and according to the matter in question.

It was some years ago enacted, that no person should be held to special bail in any action brought for less than ten pounds: but this is only observed as to writs issued out of the courts of Westminster-Hall; for the marshal's court continues to arrest and hold to special bail in actions exceeding forty shillings.

By the indulgence of the common-law, all persons might be bailed till they were convicted of the offence laid to their charge: but it is enacted, by statute, that murderers, outlaws, house-burners, thieves, openly defamed, shall not be bailed. However, this statute does not extend to the court of the king's-bench, which bails in all cases whatsoever, and may bail even for murder, &c.

Clerk of the BAILS is an officer belonging to the court of king's-bench: he files the bail-pieces taken in that court, and attends for that purpose.

BAILE, or BALE, in the sea-language. The seamen call throwing the water by hand out of the ship or boat's hold, bailing. They also call those hoops that bear up the tilt of a boat, its bails.

BAILEMENT, in law, the delivery of things, whether writings or goods, to another, sometimes to be delivered back to the bailer; that is, to him who so delivers them; sometimes to the use of him to whom they are delivered; and sometimes to a third person.

BAILIFF, an officer appointed for the administration of justice within a certain district, called a bailiwick.

BAILIFFS *Errant*, such as are appointed by the sheriff to go up and down the county, to serve writs and warrants, summon county-courts, sessions, assizes, and the like.

BAILIFFS of *Franchises*, those appointed by every lord within his liberty, to do such offices therein, as the bailiff errant does at large in the county.

There are also bailiffs of forests, and bailiffs of manors, who direct husbandry, fell trees, gather rents, pay quit-rents, &c.

BAILIWICK, that liberty which is exempted from the sheriff of the county, over which liberty the lord thereof appoints his own bailiff, with the like power within his precinct, as an under-sheriff exercises under the sheriff of the county: or it signifies the precinct of a bailiff, or the place within which his jurisdiction is terminated.

BAIOCAO, a copper coin, current at Rome, and throughout the whole state of the church, ten of which make a julio, and an hundred a Roman crown.

BAIRAM, in the Mahometan customs, a yearly festival of the Turks, which they keep after the fast of Ramazan.

The Mahometans have two bairams, the great and the little.

The little bairam holds for three days, and is seventy days after the first, which follows immediately the Ramazan. During the bairam the people leave their work for three days, make presents to one another, and spend the time with great manifestations of joy. If the day after Ramazan should prove so cloudy as to prevent the sight of the new moon, the bairam is put off to the next day, when it is kept, even if the moon should still be obscured. When they celebrate this feast, after numerous ceremonies, or rather strange mimicries, in their mosque, it is concluded with a solemn prayer against the infidels, to extirpate Christian princes, or to arm them against one another, that they may have an opportunity to extend the borders of their law.

BAIT, among fishermen, implies a substance proper to be fastened to a hook, in order to catch the different sorts of fish.

Baits are of two sorts. 1. The natural ones, or those generally living, as maggots, bobs, frogs, &c. 2. Of the second kind are all artificial baits, whether such as imitate the living baits, or pastes of several compositions and figures.

Sheep's blood and cheese are good baits in April; the bobs dried, wasps, and bees, are for May; brown flies for June; maggots and hornets for July; snails in August; grasshoppers in September; corn and bramble berries at the fall of the leaf: the red-earth worm is good for small fish all the year round; and small fish are good baits for pikes at all times.

There are several artificial baits for intoxicating of fowls, and yet without tainting or hurting their flesh: for the greater sort of land-fowls, the bait may be made thus: Take a peck, or a lesser quantity, of wheat, rye, &c. with which mix two handfuls of nux vomica; boil them together till they are almost ready to burst; strew them upon the land where you design to take the fowl, and such as eat thereof will be intoxicated, and lie as if dead. Small birds may be taken with only this alteration; instead of wheat, or the like grain, take hemp-seed, &c.

BAKER's *Central rule* for the construction of all equations not exceeding four dimensions, without any previous deduction of them, or first taking away their second term, by means of a given parabola and circle.

BAKING, the art of preparing bread, or of reducing meal of any kind, whether simple or compound, into bread. See BREAD, BISCUIT, &c.

BAKING of Porcelain, or China Ware. See CHINA Ware.

BALANCE, or BALLANCE, in mechanics, is one of the six simple powers chiefly used in distinguishing the equality or difference of weights in ponderous bodies, and likewise from hence the bulks, or quantities of matter. The balance is of two kinds, ancient and modern.

The *Ancient*, Roman, *statera Romana*, or steel-yard, consists of a beam, as AB (Plate XVII. fig. 1.) moveable on a center C, suspended near one of its extremities; the two arms CB, and CA, are kept in equilibrio by the ball B, and hooks, or other apparatus fixed on CB, to which the bodies to be weighed are applied, according to the apparatus fixed on the said arm CB for that purpose. On the arm CA is a moveable weight, as W, which shews by the scale, graduated on CA, the weight of the body applied to the arm CB. This balance, or steel-yard, is still used by some; but it is not so exact in weighing heavy bodies as the

Modern BALANCE, now generally used, which consists of a beam, or lever, suspended exactly in the middle by the *trutina*, having scales or basons hung to each extremity. This balance is re-

presented by Plate XVII. fig. 2. where AB is called the *jugum* or beam, and the two parts on each side the center C, the arms or brachia. The line on which the beam turns, or which divides it into two equal parts, is called the axis, and when considered with regard to the length of the brachia, is only esteemed a point, and called the center of the balance; and that slender part which shews the scale's preponderating, (or what is called the turn of the scale) is called the tongue.

A balance is said to be in equilibrio, when the action of the weights upon each brachium to move the balance are equal; so that they mutually destroy each other. Unequal weights can equiponderate; for if the distances from the center be reciprocally as the weights, the balances will be in equilibrio; as for instance, one ounce at nine inches distance from the center will equiponderate with three ounces at three inches distance from the center; and upon this principle the Roman steel-yard is constructed. In the Roman balance the weight used for a counterpoise is always the same, but the points of application are different or various, but the contrary in the modern balance; for in it the counterpoise is various, and the point of application the same. The principle on which both are founded, may be easily understood from the general properties of the lever. See LEVER.

The *Deceitful BALANCE* is such whose beam will hang in equilibrio without the scales, or with the empty scales, and yet shall also be in equilibrio when unequal weights are put in the scales. These kind of balances are constructed upon the same principle as the *statera*, or steel-yard, and may be made so as to cheat in any proportion. Dr. Desaguliers in Lecture 3. Problem 27th, constructed one in the following manner:

To the beam AB fig. 3. (which is 23 inches long, whose brachium CB of 11 inches in length, keeps in equilibrio about the point C, the brachium CA of 12 inches in length, by being made so much thicker, or having so much the more matter as may make amends for its being shorter,) suspend the scales D, E, in such manner that D, which weighs one part in 12 less than E, shall hang at the longest end of the beam, and they will keep each other in equilibrio; then placing 12 pound weight at G in the scale E, it will keep in equilibrio no more than 11 pounds of F, the commodity to be sold, if placed in the scale D; because then F will be to G, in a reciprocal proportion of BC to AC—Tho' such a balance may be so nicely made as to deceive the eye; yet the cheat is immediately discovered by changing the weights and the commodity F from one scale to the other; for then the owner of the scales must either confess the fraud; or add to the commodity he sells, not only what was wanting, but also as much as he intended to cheat the buyer of, and a fraction of that

that added weight proportionable to the inequality of the brachia of the balance. That is, in this case the buyer, instead of 11 pounds offered him for 12 his due, will have by changing scales $13\frac{1}{11}$ pounds.

For whereas in the first position of the balance, $F \times AC$ was equal to $G \times BC$, when G is placed in the scale D , then 12×12 will be equal to no less than CB (11) $\times$ by $13\frac{1}{11}$ G .

As the brachium CB 11 inches long :

Is to the brachium CA 12 inches long :

So will F , or the weight 12 placed in the scale D :

To $G = 13\frac{1}{11}$, or the weight of the commodity keeping the scales in equilibrio.

And therefore as this analogy gives a reciprocal proportion between the weights and their velocities, the momenta will be equal, which, with contrary directions, destroy one another: but we must remark, that in these cases the weights are supposed to hang freely from those ends of the balance to which they are fastened. Tho' in the common use of the balance the counterpoising weights or the scales generally hang freely; yet there are some cases where they do not; and in compound engines, where the balances are often a part of a complex machine, instead of weights, powers are applied to their ends in all manner of directions, and then they become levers of the first kind; such as the regulators in water-engines, beams to blow bellows, &c.

Assay BALANCE, a very nice balance used in dometical operations, to determine exactly the weight of the minute bodies.

This balance should be made of the best steel, and of the hardest kind; because that metal is not so easily spoiled with rust, as iron; and it is more apt than any other to take a perfect polish, which at the same time prevents the rust.

The structure of the assayer's scale is little different from that of common scales, otherwise than by its nicety and smallness. The longer the beam of it is, the more exact may the weight of a body be found: however, ten or twelve inches are a sufficient length. Let the thickness of it be so little, that two drachms may hardly be hung at either of its extremities, without its bending: for the largest weight put upon it seldom exceeds one drachm. The whole surface of this beam must be altogether without ornaments, which only increase the weight, and gather dust, &c. The beam is suspended in a fork, the two legs of which are steel-springs joined at top, but kept together below with a brass pliant clasp, parallel, and two lines and an half distant from each other. This clasp being taken off, and the legs of the fork being stretched out, the axis of the beam may be put into two holes for that purpose at the ends of the legs, or be taken away

from them. Let a very sharp needle be fixed in the head of the fork, standing perpendicularly downwards, if the fork is suspended, and so long, as that it may almost touch the top of the tongue of the beam, put into the fork, when in equilibrio. This needle is the mark of the equilibrium; and, that the artists may be able to observe this, the legs of the fork must be broader in that place, and have an opening two or three lines wide; this fork may be adorned at pleasure, provided the motion of the balance is not hindered by such ornaments: then take two scales made of a thin plate of silver, one inch and an half in diameter, hanging on three small silk strings, almost as long as the beam, tied together at top, with a silver hook, in form of an S, and hang them to the extremities of the beam: a smaller silver dish, or blued steel, somewhat less than one inch in diameter, belongs to each of these scales. You first put into these dishes, with a pair of pin-cers, the bodies to be weighed, or with a spoon or a small shovel, when they are pounded, and then you put them into scales; therefore the small dishes must be perfectly equal in weight. We use them, that bodies may be more conveniently put into and taken out of the scales, and that these, which are vastly thin, may not be bent or soiled, and thence rendered false by wiping.

This balance is suspended on a moveable brass or copper support, which consists of a pedestal, and of a column set upon it about twenty inches high, at the top of which comes out at right-angles an arm one inch long. At the extremity of this arm, put a small pulley three lines in diameter, another at the top of the column, and a third near the bottom of it; all which pulleys must turn very easily on their axes. At the distance of one inch and a half below the upper arm, let another arm, one inch and a half long, come out of the column at right-angles, having a hole through it two lines long, a quarter of a line broad, and placed perpendicularly below the pulley of the upper arm, to receive a small plate, one inch and a half long; and of such breadth and thickness, as that it may move freely up and down, and yet not have too much play within the hole. This plate must also have a small hook at the extremity.

And as such a balance will hardly stand still in the open air, and becomes false when spoiled with dust; it must be put together with its support into a small glass-case, having glasses at top and all round it, that you may see what is within.

Manner of using the Assay BALANCE.—Pass a silk string over the three pulleys of the support, and tie it at its upper extremity to the small hook introduced into the hole of the inferior arm; then put the support in the middle of the small case, and pass the other extremity of the silk string below, through a hole bored in the middle of the lower part of the frame, containing the window in the fore-part of the

the case, and fasten it to a small weight of a cubic form. Suspend the fork of the balance on the inferior hook of the plate. By this means, if you move backwards and forwards the weight fastened to the string, placed upon the top of the drawer jutting out beyond the fore-part of the case, the balance within is either lifted up, or let down. But you must put the bodies to be weighed, and the weights themselves, in the small silver dishes; and these, when loaded, into the scales, through the side-windows, which must be opened for that purpose. When any thing is to be added to, or taken out of them, you do it with the small pincers, or, if it is powder, with the small shovel or spoon: but you must let the balance down every time any thing is to be added or taken away, that the scales may rest upon the bottom of the case; and shut the windows before the balance is lifted up again, especially if the air is not perfectly calm.

Hydrostatical BALANCE, an instrument first invented for determining the specific gravity of bodies, both liquid and solid, in an accurate, easy, and expeditious manner.

Several methods have been proposed, and more may be still invented, to determine what proportion bodies differ from one another as to their specific gravities; yet after all, most men with good reason prefer the use of the hydrostatical balance for exactness and convenience.

It is very probable that Archimedes was the first that ever attempted this business, in which the balance is employed, with any success, in order to discover the cheat of the workmen that had defrauded king Hiero's crown; yet the way he then made use of was certainly much inferior to what is now practised, by the invention of, and great improvements in, this machine.

It is of great use in estimating the degree of purity of bodies of all kinds, the quality and richness of metals, minerals, ores, &c. as well as the proportion, mixture, adulteration, or the like, all of which the specific weight is the only judge.

The common hydrostatical balance, as represented by Plate XVII. fig. 4. needs very little explanation, it being so very simple. It has commonly a lump of solid glass in form of a heart, and sometimes in shape of a wedge, the more easily to cleave and separate the parts of those fluids in which it shall be occasionally immersed. Now this being made of a matter not liable to be injured by any liquor, and of weight sufficient to sink it in most, is convenient for the purpose, and is represented as in use by A. The machine has a fixed counterpoise for the other end of the beam, as B, which, when the glass is poised in rain or river-water, will keep the balance-beam just level, whether it be put at the top, middle, or bottom of the jar.

Now all such liquors as are specifically heavier,

that is, more buoyant than common water, will require weight to be added on the side of the immersed glass A, to restore the equilibrium: and such as are less so, or lighter than common water, will require weight to be added to the counterpoise, to bring the beam, which ought to be singularly good and true, to a horizontal position.

In comparing of two liquors, in order to find simply which of them is the heavier, 'tis of no great concern to know what the bulk or solid content of the glass bubble A, is, because the grains on either side added, to bring the beam again to a level, will sufficiently determine how much a quantity of them, equal to the bulk of the bubble, differs from rain or river-water, to which the machine is commonly adjusted; which is something more of satisfaction than from the hydrometer can be had. But how much the density of the one exceeds that of the other, or generally in what proportion, cannot be known 'till the weight of the glass bubble A, both in air and water, and consequently the weight of a quantity of the fluid under consideration in bulk equal thereto, with which it is generally compared, be first adjusted and found.

It may here be remarked, that the beam of the hydrostatical balance cannot well be too light, if it be but equal to its office without yielding or springing. The way to prove whether it be true or not, is, when you have found any exact equilibrium by it, to change both weight and scales together, end for end; and then, if no alteration appears, it is perfectly well executed; otherwise not.

A square piece of paper, weighing but one grain, may without difficulty be divided by measure into two and thirty parts of a grain; and if you desire your beam should be affected by the weight of a few of these, the rest of your apparatus must be very light also; lest the weight laid on the point of support, should make it too sluggish to move so free and finely as it properly ought to do.

Suppose then the weight of our essay-bubble A, when taken in the water, is one hundred and eighty-two, and in the air two hundred and six grains; the difference, or twenty-four grains, is the just weight of a quantity of water equal in bulk and dimensions thereto: which being known, may be received as a general standard whereby to estimate the specific gravity of liquors by this machine. For example; warm a jar of water pretty well, it will be thereby rarefied, and rendered specifically more light, and of consequence the bubble, before adjusted to that liquor cold, will, on immersing, sink therein. And by adding weight on the other side, we may easily learn how much it is thereby become specifically lighter than a like quantity of water cold; viz. merely by deducting the weight found on experiment necessary to restore the equilibrium, let us suppose three grains from

from twenty-four; so that the specific gravity of the cold water will be found to be to that of the hot, as 24 to 21, or 8 to 7.

For experiment's sake, a second trial may be made the same way, on a fluid denser than common water; as suppose strong ash-lees, replete with a lixivial salt, in which case we are to add the difference found on the immersion of the essay-bubble; suppose four grains to twenty-four; the specific gravity hereof will then be signified by the number 28, and an equal quantity of lees will be to common cold water, as 28 to 24, or 7 to 6; and to an equal quantity of the water before warmed, as 28 to 21, or 4 to 3; and thus of any other.

The specific weight of equal quantities of different liquors might indeed be also found, by filling a small phial, of known dimensions and capacity, with them successively; which ought to be first exactly tared or counterpoised on the opposite side. Their several weights then taken by a nice pair of scales, and noted down, may afterwards be compared together tolerably well.

In like manner might also the specific gravities of solid bodies heavier than water be found, was it practicable to reduce them by any means to some certain or determinate dimensions, as to the size of a cubic inch, or the like: but that being not only laborious, and expensive, and tedious, but also very inconvenient and much less exact; the beauty of the hydrostatic balance will therefore appear in assigning their comparative gravities, be their figures never so various or irregular, with very great truth, ease, and expedition.

For the weighing of solids specifically heavier, or which sink in water, hydrostatically, this instrument is provided with a small glass bucket, marked C, which in the air is exactly counterpoised by B; and in water, by adding the small weight D on the bucket-side at E, to counterbalance the buoyancy of the water on the bucket immersed. By this machine fragments of such bodies may be weighed indifferently either in water or the air; both which, in these experiments, are always carefully to be distinctly done; noting their several weights. *Clave's Motion of Fluids.*

As the learned Mr. Gravesande has greatly improved the common hydrostatic balance, and rendered it more accurate and expeditious, we shall give the reader a description of it, according to the improvements of this ingenious author.

The figure of this machine. (Plate XVI. fig. 6.) represents the balance in its hydrostatic use. We shall first describe the machine; then shew the new contrived artifice for exactness; and, lastly, give an instance of its universal use. VCG is the stand or pillar fixed in the table. From the top at A hangs, by two silken strings, the horizontal piece or bar BB; from which is suspended, by a ring at i, the fine beam of a balance l, which is

kept from descending too low on either side, by the gentle springing piece $zxyx$, fixed on the supporter M. The harness is annulated at o, to shew distinctly the perpendicular positions of the examens, by the small pointed index fixed above it. The strings by which the balance is suspended passing over two pulleys, one on each side the piece at A, go down to the bottom on the other side, and are hung over the hook, by means of a screw P, which is moveable about $\frac{1}{4}$ th of an inch backwards and forwards; and therefore the balance may be raised or depressed as much: but if a greater elevation or depression be required, the sliding-piece S, which carries the screw P, is readily moved to any part of the square brass rod VK, and fixed by means of a screw.

The motion of the balance being thus provided for, the rest of the apparatus is as follows: HH is a small table fixed upon a piece D, under the scales d and e, and is moveable up and down in a long slit in the pillar above C, and fastened at any part with a screw behind. At the point at the middle of the bottom of each scale, is hung by a fine hook, a brass wire ad, ac . These pass through two holes m, m , in the table; and to the wire ad is suspended a curious cylindric wire rs , perforated at each end for that purpose. This wire rs is covered with paper graduated by equal divisions, and is about five inches long. In the corner of the table at E, is fixed a brass tube, in which a round wire hl is so adapted as to move neither too hard nor too freely by its flat head I: upon the lower part of this moves another tube Q, which has friction enough to cause it to remain in any position required; to this is fixed an index T, moving horizontally when the wire hl is turned about, and therefore may be easily set to the graduated wire rs .

To the lower end of the wire rs hangs a weight L; and to that a wire pr , with a small brass ball g , about $\frac{1}{4}$ th of an inch in diameter. On the other side, to the wire ac , hangs a large glass bubble R to a horse-hair. Let us, at present, suppose the weight L taken away, and the wire pn suspended from S; and, on the other side, let the bubble R be taken away, and the weight F suspended in its room at c. This weight F, we suppose to be such as will keep in equilibrio with the several parts appended to the other scale, at the same time that the middle point of the wire pn is in the surface of the water in the vessel N.

The wire pn is to be of such a size, that the length of one inch shall weigh four grains. Hence it is evident, since brass is eight times heavier than water, that for every inch the wire sinks in the water, it will become half a grain lighter; and half a grain heavier for every inch it rises out of the water: consequently, by sinking two inches below the middle point, or rising two inches above

above it, the wire will become one grain lighter or heavier.

And therefore, when the middle point is at the surface of the water in equilibrio, the index T be set to the middle point *a* of the graduated wire *rs*, and the distance on each side *ar* and *as* contain 100 equal parts; then, when in weighing bodies the weight is desired to the hundredth part of a grain, it may easily be had by proceeding in the following manner.

Let the body to be weighed be placed in the scale *d*, and put the weights in the scale; and let these be so determined, that one grain more shall be too much, and one grain less too little. Then the balance being gently moved up or down by the screw P, till the equilibrium be nicely shewn at *o*; and then, if the index T be at the middle point *a* of the wire *rs*, it shews the weights put into the scale *e* are just equal to the weight of the body.

But if the index T stand at any part between *a* and *r*, it shews the number of grains of the scale *e* were more than equal to the weight of the body in the scale *d*; because the wire *pn* is now made lighter by sinking below the middle point. Thus, suppose the weights put into the scale *e* were 1095 grains, and the index T cuts the 36th division above *a*, it shews that 36 hundredths parts of a grain are to be added, or that the weight of the body is 1095,36 grains.

On the other hand, had the index stood at 36, the division below *a*, it would have shewn the weights in the scale *e* were more than equal to the weight of the body by 36 hundredths of a grain, and that then the weight of the body was 1094,64 grains. By this method we find the absolute weight of the body; the relative weight is found by weighing it hydrostatically in water, as follows: Instead of putting the body in the scale *d*, as before, let it be appended with the weight F at the hook *e*, by a horse-hair as at R, supposing the vessel of water O were taken away; then the equilibrium being made, the index T standing between *a* and *r*, at the 36th division, shews the weight of the body 1095,36 grains. As it thus hangs, let it be immersed in the water of the vessel O, and it will become lighter by much; the scale *e* will descend till the beam of the balance rests on the supporter *z*. Then suppose 100 grains, put into the scale *d*, restore the equilibrium precisely, so that the index T again pointed to the 36th division above *a*; it is plain the weight of an equal bulk of water would, in this case, be exactly 100 grains. But if 100 grains in the scale *d*, cause it to preponderate a little, then, by turning the screw P, the balance may be raised, till the wire *pn* becoming heavier, restores the equilibrio. Let now the index T cut the 6th division above *a*; then $36 - 6 = 30$, which shews that the wire *pn* is now

$\frac{1}{10}$ of a grain heavier than before; therefore the weight of the water is only 99,7 grains; whence its gravity to that of the body is as 99,7 to 1095,36, as required.

After a like manner may this balance be applied to find the specific gravities of fluids, which will not be difficult to those who apprehend what has been already said.

In practice, it will be necessary to use great precautions in every particular; the wire *pn* should be oiled, and then wiped as clean as possible; enough will remain to prevent the water adhering thereto; also the balance ought to be raised very gently, and when come to an equilibrium, should be gently agitated, to see if it will come so again.

BALANCING, in the marine, a certain manner of contracting or reducing a sail in a storm, in contradistinction to reefing, which is common to all the principal sails, whereas balancing is peculiar to the mizen, and to mainfairs that are set on a boom. Balancing the mizen is performed by gathering a certain portion of the sail together at the peak or upper-corner, fastening it to the mizen-yard, at some distance within the yard-end. A boom-main-sail is balanced, after all the reefs are taken in, by tying a similar portion of the outmost or aftmost lower-corner, called the clew, in the same manner to the bottom, having first wrapped a piece of canvas round it, which is done in both cases, to prevent the sail from being fretted by the cord which fastens it. See REEF.

BALANI MARINI, certain multivalve shells, usually growing in clusters on the shells of the larger sort of the sea shell-fish: sometimes they are found large, loose, and petrified, at a great distance from the sea; in which state they are distinguished by the name of balanites.

BALASS, or BALLASS, the name of a kind of ruby. See the article RUBY.

BALAUSTINE, large rose-like flowers, of a deep red colour, set in long bell-shaped tough cups. They are the produce of the wild or double-flowered pomegranate tree, a low prickly tree or shrub, with long narrow leaves, bearing a brownish acerb fruit, about the size of an orange; a native of the southern parts of Europe; and cultivated in some of our gardens on account of the beauty and continuance of its flowers. The shops are usually supplied with the dried flowers from abroad, tho' those of our own growth do not appear to be anywise inferior to the foreign.

Balaustine flowers are mildly astringent and corroborant; of a moderately rough and somewhat bitterish taste, and of little or no smell or particular flavour. They give out their astringent matter, together with a pale red colour, both to water and rectified spirit: the extracts obtained by inspissating

spissating the tinctures, in which the active parts of the flower are concentrated, are pretty strongly styptic.

BALCONY, in architecture, a projecture in the front of a house, or other building, supported by pillars, or consoles, and encompassed with a balustrade: or it is a kind of open gallery, for people to stand in, to behold any public show, or for taking the air in. They are usually level with the first floor, and are made of wood, or iron.

BALDACHIN, of **BALDAQIN**, in architecture, a building in form of a canopy, supported by pillars, and frequently used as a covering to insulated altars. Some also use the term baldachin for the shell over a door.

BALE, in commerce, is said of merchandizes packed up in cloth, and corded round very tight, in order to keep them from breaking, or preserve them from the weather.

BALE-GOODS, among the English merchants, are all such as are imported or exported in bales; but the French give that name to certain hardwares, and other sort of merchandize, which come to Paris, and are commonly made by bad workmen of indifferent materials.

BALISTA, a machine used by the ancients for shooting darts; it resembled in some measure our cross-bow.

BALIVO AMOVENDO, in law, was a writ for removing a bailiff from his office, for want of having sufficient land in his bailiwick to answer the king and his people, according to the statute of Westminster, 2 reg. Orig. 78.

BALK, among builders, is sometimes used for the summer-beam of a house; sometimes for the poles and rafters which support the roofs of barns, &c. and sometimes for the beams used in making sea-holds.

BALL, a spherical and round body, either naturally so, or turned into that form. There are balls of common wood, of box, of iron, &c.

BALL, in the military and pyrotechnical arts, is a composition of divers ingredients, generally of the combustible kinds, serving to burn, smoak, give light, &c.

Bomb BALLS are made in the same manner as grenades; a bomb is first put at the bottom of a bag, then a bed or layer of three bombs, and a bed or layer of powder are laid in alternately. These bombs are six inches in diameter, and two or three layers of them are contained in a ball.

Fire BALLS, in military affairs, are either round or oval, filled with different compositions, all difficult to be extinguished. These are thrown to a great distance by a mortar, and some of a smaller size are thrown by hand like grenades. Their use is to give a light by which an enemy may be discovered in the dark, and fired upon with more certainty: they are also used to fire magazines of

forage, and houses in a town which is attacked. And to prevent any one from coming near them and attempting to extinguish the fire, they are filled in the same manner as carcasses with grenades, and small ends of musket-barrels, charged with bullets, which keep those at a distance, who might otherwise throw something on this fire-work to prevent its effect. See **CARCASSE**, **GRENADOE**, **MORTAR**.

Grenado BALLS, in military affairs, are sacks made of a very coarse dry cloth. They are filled by putting in first about two pounds of powder at the bottom of the bag, with a grenado; this first layer, or bed, is covered with four grenades, the intervals between them are then filled up with powder, and they are covered with a layer of powder, as the former; upon which, four other grenades are laid, in the same manner as the first. Four different layers of powder and grenades are thus disposed alternately, which ought to fill the bag, leaving only sufficient room to tie it up at the mouth, into which a fuse is inserted, and strongly bound up with it; after which, the whole is first dipped into pitch or tar, and put into another sack, which is first dipped, as the former, into pitch or tar, and then into water, to prevent it from sticking to the places where they are kept for use: the fuses of the grenades contained in this bag, are covered with *etrapelles*, which is a kind of match consisting of the finest cotton, well soaked in brandy, and priming, or pounded powder, the fire of which instantly communicates itself to all parts; and by this means, the grenades are more certainly fired than if covered with powder only.

Pebble BALLS, are made in the same manner as grenado and bomb balls; but in these, instead of grenades and bombs, pebbles are made use of; and these balls are contrived so as to burst in the air, that the pebbles they are filled with may fall like hail upon the places designed.

Light BALLS, *globi lucentes*, are such as diffuse an intense light around; or they are balls which, being cast out of a mortar, or the hand, burn for some time, and illuminate the adjacent parts.

Smoak or Dark BALLS, those which fill the air with smoak, and thus darken a place to prevent discoveries.

BALL of a Pendulum, the weight at the bottom. In shorter pendulums, this is called the bob.

BALL, among the Cornish miners, signifies a tin-mine.

BALL, among printers, a kind of wooden tunnel stuffed with wool, contained in a leather cover, which is nailed to the wood, with which the ink is applied on the forms to be wrought off.

Harpe BALLS, among farriers, a kind of cordial medicine, administered in the form of balls, supposed of great virtue for feeding and strengthen-

ing found, as well as healing and raising unsound horses.

Chewing BALLS are those which the horse keeps champing or masticating in his mouth, a considerable time, without swallowing. These are chiefly used for a lost appetite, a thing very incidental to horses.

They are usually made of asa-foetida, liver of antimony, juniper, bay-wood, and pellitory of Spain, beaten and incorporated into a mass with verjuice. The method of administration is to wrap one of the balls in a linen cloth, and, having a string fastened to it, make the horse chew it three or four hours at a time. *Rust Dict.*

BALL Vein, in mineralogy, a name given by the miners of Suffex to a sort of iron ore, common there, and wrought to considerable advantage.

BALL and SOCKET is an instrument made of brass, with a perpetual screw, to hold a telescope, quadrant, or surveying instrument, on a staff, for various uses.

BALLAD, or *BALLET*, a species of song, adapted to the lower class of people.

BALLANCE, or *BALANCE*, in mechanics; see *BALANCE*.

BALLANCE of Trade. See *TRADE*.

BALLANCE of a Clock or Watch. See the articles *CLOCK* and *WATCH*.

BALLAST, in the marine, a certain quantity of stone, iron, gravel, or other materials, deposited in a ship's hold, when she has either no cargo, or too little to sink her to a sufficient depth in the water, that she may be enabled to carry sail without danger of overturning. There is often great difference in the quantity of ballast requisite to prepare ships of equal burthen for a voyage; the quantity being always more or less in proportion to the sharpness or flatness of the bottom, which seamen call the floor.

It is very far from being a matter of indifference how a ship is ballasted; for although seamen, in general, know very well that few vessels will carry a stout sail, till they are laden so deep, that the surface of the water may nearly glance on the extreme breadth amidships; yet there is more than this general knowledge required to ballast her with propriety; since if she has a great quantity of heavy ballast, as lead, iron, &c. in her bottom, it will place the center of gravity too low in the hold; and although, by this means, she will be enabled to carry a great sail; yet she would sail very badly, and be in danger of being dismasted by her sudden jerks and violent rolling. Seamen commonly endeavour to prevent this, by raising the weighty ballast with dinnage, *i. e.* boughs of trees, faggots, or such materials, by which means the center of gravity being more elevated, the ship will roll easily, and sail smoothly through the water. On the other hand, if she be too light, she will incline till her

extreme breadth rests upon the water, and consequently want sufficient stability for a fresh wind; whereas, if she is well ballasted, she will carry a good sail, incline but little, and ply well to the windward. See *GRAVITY*, *SAILING*, *TRIM*.

BALLIAGE, in commerce, a small duty paid to the city of London by aliens, and even denizens, for certain commodities exported by them.

BALLISTA. See the article *BALISTA*.

BALLOON, or *BALLON*, in a general sense, implies any hollow body of a spherical form, be its composition or uses what they will.

BALLOON, in chemistry, is a large receiver of a round form, and very short neck.

BALLOON, in architecture, signifies a round ball or globe, placed on the top of a pillar, &c. by way of crowning.

BALLOON, in pyrotechny, is a kind of bomb made of paste board, and played off in fire-works, either in the air or water, in imitation of a real bomb.

BALLOTA, in botany, a genus of plants, the flower of which is monopetalous and cloven, the upper lip being erect and crenated, and the lower obtuse, and divided into three segments. It contains four filaments, two of which incline to the upper-lip: the germen is quadrifid, supporting a style the form of the stamina; it is destitute of a pericarpium, the cup inclosing four ovated seeds.

BALLOTADE, or *BALOTADE*, in the manege, the leap of a horse between two pillars, or on a straight line, made with justness of time, and with the aid of the hand and calves of the legs; and in such a manner, that, when his fore-feet are in the air, he shews nothing but the shoes of his hinder feet, without jerking out.

BALLS, or *BALLETS*, in heraldry, make a frequent bearing in coats of arms, though they are never called by those names, but acquire other denominations from their several colours. Thus, when the colour is or, they are termed *besants*; when argent, *plates*; when azure, *burts*; when gules, *torleaux*; when vert, *pomeis*; when sable, *agresses*; when purple, *golpes*; when tanne, *oranges*; and when sanguine, *guzes*.

BALLUSTER, in architecture, a kind of small pillar used in ballustrades.

BALLUSTRADE, a row or series of ballusters joined by a rail, and fixed on a terrace or the top of a building by way of security; as also to inclose balconies, altars, fronts, stair-cases, &c.

BALM, or *BALSAM*; see *BALSAM*.

BALM, or *BAUM*, in botany; see *BAUM*.

BALNEUM, a term much used by chemists to signify a vessel filled with some matter, as sand, water, or the like, in which others are placed for performing various operations that require less heat than a naked fire.

BALNEUM Arenosum, or *Siccum*, a sand, or dry heat; a vessel filled with sand, ashes, or filings of steel.

BALNEUM Mariæ, or *Moris*, a water-bath, or a vessel filled with water, which is made to boil, and in which the vessels containing the ingredients are placed.

BALNEUM Vaporis, a vapour-bath, or when the vessel containing the ingredients, on which the process is to be performed, is heated by the vapour arising from boiling water.

BALSAM, *Balsamum*, an oily, resinous, and odorous substance, flowing either spontaneously, or by incision, from certain plants, of great virtues in the cure of several disorders.

BALSAM of Gilead, or of *Mecca*, *Opebalsamum*, the most precious of all balsams; and commonly called balm of Gilead.

It is the produce of certain trees, which grew formerly in the valley of Jericho; but after the conquest of the Holy Land by the Turks, were removed to Grand Cairo, and afterwards to Mecca, where the balsam plantation is said to be now guarded by janizaries, and the resinous juice collected for the sultan only.

The precious balsam exudes in very small quantity, from slight incisions made in the bark: according to Prosper Albinus, it is at first white, of a very strong penetrating smell, of the turpentine kind, but sweeter and more fragrant, and of a bitter, acrid, astringent taste. It looks in part turbid and thick, like the oil newly expressed from olives; afterwards it grows extremely thin, limpid, and light; its colour changes to a greenish, then to a gold yellow, and, by long keeping, to that of honey: it now grows thick like turpentine, and loses much of its fragrance.

Inferior sorts of balsam are said to be obtained by boiling the branches in water. When the liquor begins to boil, a thin oil arises to the surface, and on continuing the coction a grosser and thicker one.

It is used in medicine to open obstructions of the lungs, and to heal erosions from acrimony, and the worst kinds of ulcerations. It is also prescribed in asthma, pleurisy, and whenever expectoration is necessary, in internal bruises, and to cleanse the urinary passages.

BALSAM of Tolu is commonly of a thicker consistence than the foregoing, and more of a brownish colour. When fresh, it has an exceeding pleasant smell, somewhat resembling that of citrons.

It is said to be the produce of New Spain, and to exude in very hot weather from incisions made in the bark of a small tree of the fir kind, called *Tolu*.

We have no particular description of the tree which produces this balsam. Linnæus has given

its generical characters, under the name of *toluifera*; and in these it differs greatly from the fir and pines, to which it is commonly resembled. The balsam is one of the most elegant and grateful of the substances of this class, and does not lose much of its fragrance when by age it grows consistent. It yields very little essential oil in distillation, but impregnates the distilled water strongly with its flavour. By dissolving in this water, in a gentle warmth, a proper quantity of fine sugar, we obtain a balsamic syrup, greatly superior to that made in the common manner with a decoction of the balsam.

Its virtues are the same with that of Gilead, and is given in convulsions, and other disorders of the breast, sometimes in the form of pills, and sometimes in electuary; but the best form of giving it is in emulsion, dissolved in the yolk of an egg, and then mixed with water.

BALSAM of Copaiba, *Copahu*, *Copaif*, *Campaif*, *Copalmya*, or *Gamelo*, is obtained from a tree of the same name, growing in the Brazils, near Rio de Janeiro.

This balsam is of a pale yellowish colour, and thin consistence. It is observable, that on mixing this juice with the watery spirit of sal ammoniac, made by quick-lime, a frothing, or effervescence, as it is called, ensues, stronger and of longer continuance than that produced by the same spirit with any other natural balsam: by this mark we may distinguish the genuine copaiba from the thin resin of the turpentine or fir-tree, which is frequently mixed with or vended for it. This balsam is at present of very common use as a medicine.

It is observable also of this balsam, that on being distilled in a retort, it gives over towards the end of the operation, an oil of a fine blue colour, preceded by a limpid, and a yellowish or brownish one. Distilled with water, it yields a large quantity of a limpid essential oil: from sixteen ounces I have gained eight.

The copaiba-tree is one of the large forest trees of Brazil and some other parts of America. Mr. Ray calls it *Arbor balsamifera Brazilianis fructu manspermo*. The leaves are roundish and oval, the flowers pentapetalous, the fruit a pod, containing a kernel like a filbert. The wood is of a deep red colour, and great hardness; and hence is employed in ornamental mechanic works, and is said to be used also in dying. The balsam is extracted by making deep incisions in the trunk of the tree, in the summer heats; if this operation is performed too early, no juice exudes, in which case the wounds are for a time closed up. It is said that twelve pounds of balsam issue from one tree in a few hours; but that after once bleeding, it never affords any more.

It is more deterfve and more fragrant than common turpentine; passes very quickly by urine, and
greatly

greatly assists in cleansing those passages; for which reason it is frequently given in gonorrhœas, and all obstructions and ulcerations of those parts.

BALSAM of Peru is obtained from certain trees of Peru and Mexico, differing somewhat from one another in appearance, and somewhat also in the quality of their juices.

The balsam-tree described, by Pifo, under the name of *cabureiba*, has small leaves like those of the myrtle, and a thick ash-coloured bark, covered with a very thin red one; under this is lodged a yellowish balsam, that impregnates the whole substance of the bark, which by age becomes more and more fragrant. Hernandez describes this balsam-tree, as having leaves like those of the almond, and a thick bark like cork, from which the balsam flows upon wounding the outer thin rind. Plunket mentions a tree of the same kind in Virginia, by the name of *Arbor Virginiana*, *Pisaminis folio*, *Baccata Benzoinum redolens*.

This balsam is of a thick consistence, like honey; of a dark black colour in the mass, but when spread thin of a clear reddish or yellowish brown, of an agreeable strong smell, somewhat approaching to that of a mixture of benzoine and storax, and of a bitterish pungent taste, easily inflammable, not in the least miscible with water, nor rendered turbid or white on being agitated with that fluid. It becomes soluble in water, like the other balsams, by the mediation of yolk of eggs, or of sugar; when dissolved by the latter, it soon separates from the water, whilst the former keeps it much longer suspended.

In distillation with water, it yields a small quantity of a fragrant essential oil. Hoffman prepares also a grateful spirit, by drawing over spirit of roses from a mixture of the balsam with half its weight of salt of tartar, divided by moist sand. Distilled in a retort with an open fire, it affords a butter like that of benzoine, and oftentimes a considerable quantity even of concrete saline flowers, similar to those procured from that resin.

It is of a heating and drying quality, and is frequently used externally in the cure of wounds. The perfumers also use it on account of its agreeable smell.

Odoriferous BALSAMS are a fragrant kind of unguents, generally of a thick consistence, composed of some fatty, dense juice, joined with some distilled oils of various kinds.

Boerhaave's method of preparing these balsams, is this: Melt an ounce of fine pomatum, in a China vessel, over a small and perfectly clear fire; then gradually add a dram of white wax, shaved into thin pieces: after these are perfectly blended together, remove the vessel from the fire; and when the matter begins to thicken in cooling, drop in, by slow degrees, a dram of any of the fragrant

essential oils; keep the whole continually stirring, all the time the oil is dropping in, that it may perfectly mix: after which, let the vessel in cold water, that the whole matter, immediately condensing by the cold, may keep in the oil and spirit. When the balsam is thoroughly cold, put it immediately up in vessels of lead or pewter; and, if these are close covered, it will keep perfect a great many years.

Instead of pomatum and wax, the expressed oil of nutmeg may be used in this process, after it has been washed in water, till perfectly insipid, white, and inodorous.

If these balsams are required to be of any colour, it may be easily given at pleasure. A scruple of fine cochineal, in fine powder, will tinge the balsam of a fine purple; or the same quantity of the inspissated juice of buckthorn berries, to a fine green; a little native cinnabar will turn it scarlet: turmeric, yellow; and smalt, to a beautiful blue. Any of these may be used at pleasure, provided that they have no ill smell, or hurtful properties.

These balsams are prepared as rich perfumes, to raise the languid spirit; and the noblest and richest of the essential oils should therefore be used in them. The oils, principally directed by Boerhaave to this purpose, are those of balm, calamus aromaticus, cinnamon, cedar, citron, cloves, jasmine, lavender, white lilies, marjoram, mace, nutmegs, origanum, oranges, both those of China and Seville; roses, rhodium, and yellow saunders; to which may be added, the natural balsams of Peru and Gilead; these two being spontaneously fragrant without distillation. *Boerhaave's Chemistry.*

BALSAMICS, in pharmacy, softening, restoring, healing, and cleansing medicines, of gentle attenuating principles, very friendly to nature.

These medicines, on account of their fine, subtil, and volatile oil, are not only grateful and agreeable to the constitution, but act upon the fluids, as well as the solids, of human bodies; diffusing their virtues through every part, and supplying the blood and humours with a seasonable reinforcement of sulphureous, warm, and ethereal parts, increasing their intestine motions, and conveying vigour to the vital juices.

These medicines may be used with good success, both internally and externally, in all diseases of the head, nerves, spinal marrow, stomach and heart; such as palsies, apoplexies, numbness and torpor of the senses, weakness of the memory, difficulty of hearing, excessive weakness, and faintings; they are also of singular service in most disorders of the stomach and intestines, and are exquisitely adapted to the old and infirm.

BALSAMINA, the female balsam, in botany, the name of a genus of plants, whose flowers are of the polypetalous anomalous kind: the flowers

come

come out from the joints of the stalks upon slender foot-stalks about an inch long, each sustaining a single flower, which is composed of five large unequal petals, which in front are shaped like the lip-flowers; at their base they have a long tail, which is crooked; these are succeeded by an unilocular capsule, opening with an elastic force in five valves: the seeds it contains are fixed to the axis or placenta.

The most beautiful and valuable kind are those which produce double flowers, of which there are three sorts, finely striped with pink, scarlet, or purple, so as to appear almost as beautiful as a carnation, and are much noticed by the curious. These plants are raised on hot-beds in the spring, and nearly managed as the *amaranthus*. See *AMARANTHUS*. As these flowers are apt to degenerate, so as in a few years to become single; the best method to preserve their plenitude of petals, is by changing seeds with some person who lives at a distance, and can be depended upon for his care in the choice of blossoms for seed; for all single flowers should be plucked off so soon as they open, likewise all double flowers, which are of one colour, reserving only those which are both double and striped. This genus of plants is called by Linnaeus, *impatiens*.

BALSAMITA, in botany, a species of tansey, called also costmary; a corymbiferous plant, the roots of which are hard, fleshy, and creep in the ground. Its lower leaves are about the size of those of garden-mint, of a yellowish green colour, elegantly serrated at their edges. The stalks rise from two to three feet high, and send out branches from the side; they are furnished with oval sawed leaves like those at the bottom, but smaller, and sit close to the stalk. The flowers are produced at the top of the stalks in a loose corymbus, are naked, and of a deep yellow colour; they appear in August, but produce no seeds in England; the whole plant has a soft pleasant odour.

It is propagated by parting its roots in autumn. Where these plants are cultivated for use, they should be planted in beds at about two feet distance, that they may have room to grow; for in two years the roots will meet, so that every other year they should be transplanted and parted, to keep them within compass.

In medicine, the leaves chiefly are used as a stomachic, cephalic, carminative, and deobstruent; they are also externally applied by way of fermentation, or bathing, in order to strengthen the joints, &c.

BAMBOE, or *BAMBOW*, as they spell that word in the Indies, in botany, the name of a plant that multiplies very much by its root, from which springs a ramous or branchy tuft, after the manner of the European reeds; of which, as well as the

sugar-cane, it is a species. The Indian bamboo is the largest kind of cane hitherto known. It is of an extraordinary height and bigness when it bears its blossom; each shoot or cane is often at the bottom as large as a man's thigh, and decreases gradually to the top, where it bears a blossom or flower, like our reeds, in their proper season.

The bamboo grows in all the maritime countries of the East-Indies. Its leaves are like those of the other canes or reeds, but neither so long nor so broad at their base. With these bamboes the Indians build their houses, and make all sorts of furniture, in a very ingenious manner. The wood is so hard and strong, that they serve very well to make piles for supporting their little houses, built over rivers, or in plains overflowed at some seasons of the year with water. They also make with this wood all sorts of utensils for their kitchens and tables. The thickest bamboes serve to make the sticks or poles with which the slaves or other persons carry those sorts of litters which are called palanquins, so generally used in all the East. They also make of that wood a kind of pails, in which the water keeps extremely cool.

BANANA-TREE, in botany, a species of the musa, or plantain, growing plentifully in the West and East-Indies. This plant rises with a soft herbaceous stalk, marked with dark purple stripes and spots, and grows fifteen feet high and upwards: the lower part of the stalk is often as large as a man's thigh, diminishing gradually to the top, where the leaves come out on every side: these are often six feet long, and above a foot wide. The fruit is six or seven inches long, and covered, when ripe, with a yellow and tender skin. It grows on a stalk which bears a bunch or cluster of bananas; when the bunch is gathered, they cut off the stalk, otherwise it would bear no more fruit. The pulp of the fruit is very soft, and of a pleasant taste, and is generally eaten in the hot countries by way of desert. It is said to be very nourishing, to excite urine, and provoke to venery.

BAND, in a general sense, some small, narrow ligament, wherewith any thing is bound, tied, or fastened.

BAND, in architecture, a general name for any flat, low member, or moulding, that is broad, but not very deep.

BAND of Soldiers, in military affairs, those who fight under the same flag or ensign.

BAND of Pensioners, are a company of one hundred and twenty gentlemen, who receive a yearly allowance of one hundred pounds for attending on his majesty on solemn occasions.

BAND is also the denomination of a military order in Spain, instituted by Alphonfus XI. king of Castile, for the younger sons of the nobility, who, before their admission, must serve ten years,

at least, either in the army, or at court; and are bound to take up arms for the catholic faith against the infidels.

BAND, in surgery; see **BANDAGE**.

BANDAGE, in surgery, a fillet, roller, swathe, &c. applied to any part of the body.

That bandages are very useful, and even necessary, for curing the disorders of the human body, is evident, not only from the testimonies of Hippocrates, Galen, and other eminent physicians, but also from this, that there can scarcely be any operation, in surgery, performed successfully without their assistance: for should a surgeon perform an operation with the greatest care, but miscarry in the application of the bandage, all his endeavours would be to no purpose; and more especially in the treatment of wounds, fractures, luxations, and amputations: and we often find, that, in fractures and luxations, after a proper reduction of the parts, the cure depends more on a skilful application of the bandage to the part affected, than on the medicines: and in the case of violent hæmorrhages, a proper application of the bandage and compresses proves the most effectual and speedy remedy, as must be acknowledged by every one who has any skill in surgery; not to mention that the applying and making a bandage, after a genteel and ready manner, is justly reckoned among the good qualifications of a surgeon, as it gains him the esteem of the spectators, and the confidence of his patient, which is of great influence in forwarding the cure; for both the one and the other judge of a surgeon's other abilities by his performance on such occasions.

BANDALEER, or **BANDELEER**, in military affairs, a large leathern belt, thrown over the right shoulder, and hanging under the left arm; worn by the ancient musketeers, both for the sustaining of their fire-arms, and for the carriage of their musket charges, which being put up in little wooden cases, coated with leather, were hung, to the number of twelve, to each bandaleer.

BANDELET, or **BANDELET**, in architecture, any little band, or flat moulding, as that which crowns the Doric architrave.

BANDEROLL, a little flag, in form of a guidon, extended more in length than breadth, used to be hung out on the masts of vessels, &c.

BANE-BERRIES; see **ACTÆA**.

BANDITTI, a term peculiarly denoting companies of highwaymen, common in Italy and France; but sometimes also used, in a more general sense, for robbers, pirates, out-lawed persons, ruffians, &c.

BANIAN-DAYS, a cant-name given by seamen to those days in which they are allowed some other species of provision, as pease, butter, cheese, &c. in the room of flesh-meat.

BANIANS, a religious sect in the empire of the Mogul, who believe a metempsychosis, and will therefore eat no living creature, nor even kill noxious animals; but endeavour to release them when in the hands of others.

The Banians are said to be so fearful of having communication with other nations, that they break their cups, if one of a different religion has drank out of them, or even touched them. It is said, that if they happen to touch one another, they purify and wash themselves before they eat, or enter their own houses. They carry, hanging to their necks, a stone, called tamberane, as big as an egg, and perforated in the middle, through which run three strings: this stone, they say, represents their great god, and upon that account they have great respect shewn them by all the Indians.

BANISHMENT, a kind of punishment, whereby the guilty person is obliged to leave the realm.

There are two kinds of banishment; one voluntary, and upon oath; the other upon compulsion, for some crime or offence: the former, properly called abjuration, is now ceased; the latter is chiefly enjoined by judgment of parliament, or other courts of justice.

By *Magna Charta*, none shall be outlawed, or banished his country, but by lawful judgment of his peers, according to the law of the land, 9 Hen. III. 29.

BANISTERIA, in botany, a genus of plants producing papilionaceous flowers, and are natives of several parts of the West-Indies: one of the species, which grows naturally in Jamaica, sends forth a woody stalk, which twists itself round the neighbouring trees, and raises itself to their tops. It is garnished with leaves as large as those of the bay-tree, and of the same thickness, growing opposite in pairs; the flowers are produced in long branching spikes at the ends of the branches, and are of a yellow colour, composed of five small leaves; these are succeeded by two or three winged seeds, like those of the greater maple, from which circumstance it has been called by some the climbing maple.

BANK, in commerce, a common repository, where many persons agree to keep their money, to be always ready at their call or direction: or certain societies or communities, who take the charge of other people's money, either to improve it, or to keep it secure.

BANK, in hydrography, an elevation of the ground or bottom of the sea, that is often so high as to appear above the surface of the water, or at least so little below it, as not to permit a vessel to float over it.

In this sense, bank amounts nearly to the same

as shallows, flats, &c. The shelves that have rocks under water, are distinguished by other names, as ridges, reefs, &c.

Banks are usually marked by a beacon or buoy: on charts, sand-banks are commonly marked by little dots, and ridges of rocks by crosses. The principal banks in the Western Ocean are, the banks of Newfoundland, and the Bahama bank: the chief of those at Newfoundland is called the grand bank, which is of a vast extent, being nearly two hundred and fifty miles in length, reaching north and south; its usual depth is from twenty to fifty fathoms; and this is the great scene of the cod-fishery, which is so capital an article in European commerce.

An exact knowledge of the banks, their extent, and the different depths of water on them, constitutes a very essential portion of the science of a pilot, or master of a ship. If the vessel be large, and draw much water, great attention will be necessary to avoid the banks; if, on the contrary, it be small, the same banks afford a sure asylum, where it may brave the largest ship, that dare not follow it to so dangerous a retreat. Many small vessels have escaped the pursuit of their enemy, by means of this hospitable barrier.

BANKER, a person who trafficks and negotiates in money; who receives and remits money from place to place by commission from correspondents, or by means of bills or letters of exchange.

BANKER, in bricklaying, a piece of timber whereon they cut the bricks.

The banker is six feet long, or more, according to the number of men to work at it, and nine or ten inches square: it is to be laid on two piers of timber, three feet high from the floor they stand on.

BANKING, the making of banks to oppose the force of the sea, rivers, or the like, and secure the land from being overflowed thereby.

With respect to the water which is to be kept out, this is called banking; with respect to the land, which is thereby to be defended, imbanking.

BANKING, in a salt work, the raising a fence against the sea, whereby its waters may be kept out, excepting so much as is necessary for the preparation of the salt.

BANKRUPT, any person, either man or woman, that by trading hath gotten other persons goods into his or her hands, and concealth himself from his creditors. It is not buying or selling of lands, but of personal things, that will make a person liable to be a bankrupt; nor is it buying only, but both. Every one that gets his livelihood by buying and selling in trade, may fall under a state of bankruptcy upon his failing: but adventurers in the East-India company, members of the bank of England, or of the South-sea com-

pany, shall not be adjudged bankrupts, in respect of their stock: also no person concerned as receiver-general of the taxes, &c. shall be a bankrupt. If a merchant gives over trade, and some years after becomes not solvent for money owed while a merchant, he is a bankrupt; but if for new debts continued on new security, it is otherwise.

BANKRUPTCY, the failure, absconding, and relinquishing of traffic in a merchant, a banker, or any other trader. See the article **BANKRUPT**.

The French make this difference between a bankruptcy and a failure, that the first is supposed voluntary and fraudulent, and the latter constrained and necessary, by means of accidents, &c. A failing, breaking, or stopping of payment, diminishes the merchant's credit; but does not note him with infamy, as bankruptcy does.

When a merchant fails to appear at the Exchange, without apparent reason, it is called a failing of preference: the bankruptcy becomes open from the day he absconds, or the seal is affixed to his effects.

BANN, or **BAN**, *Bannum*, or *Bannus*, in the feudal law, a solemn proclamation or publication of any thing. Hence the custom of asking, or bans, before marriage.

BANN, in military affairs, a proclamation made in the army by beat of drum, sound of trumpet, &c. requiring the strict observance of discipline, either for the declaring a new officer, or punishing an offender.

BANN of the *Empire*, an imperial proscription, being a judicial punishment, wherewith such as are accessory to disturbing the public peace, are judged unworthy of the immunities and protection of the empire, and are outlawed or banished, &c.

BANNER denotes either a square flag, or the principal standard belonging to a prince.

We find a multiplicity of opinions concerning the etymology of the word banner; some deriving it from the Latin *bannum*, a band or flag; others, again, from the German *ban*, a field or tenement, because landed men alone were allowed a banner; and, finally, there are some who think it is a corruption of *panniere*, from *pannus*, cloth, because banners were originally made of cloth.

BANNERET, an ancient order of knights, or feudal lords, who possessing several large fees, led their vassals to battle under their own flag, when summoned thereto by the king.

This order is certainly most honourable, as it never was conferred but upon some heroic actions performed in the field. Anciently there being but two kinds of knights, great and little, the first were called bannerets, the second batchelors; the first composed the upper, and the second the middle nobility.

In France they are said to transmit their degree to their posterity: but in England it dies with them. We have had none of this order created in England, since the time of king Charles I. so that this order is now become extinct among us.

The form of the banneret's creation was this; on a day of battle, the candidate presented his flag to the king, or general, who cutting off the train, or skirt thereof, and making it a square, returned it again; the proper banner of bannerets, who, from hence, are sometimes called knights of the square flag.

BANQUET, in the manege, that small part of the branch of a bridle that is under the eye, which being rounded like a small rod, gathers and joins the extremities of the bitt to the branch, and that in such a manner, that the banquet is not seen, but covered by the cope, or that part of the bitt that is next the branch.

BANQUET LINE, an imaginary line drawn in making a bitt along the banquet, and prolonged up or down to adjust the designed force or weakness of the branch, in order to make it stiff or easy.

BANQUET, or **BANQUETTE**, in fortification, a little foot bank, or elevation of earth, forming a path, which runs along the inside of a parapet, upon which the musketeers get up in order to discover the counter-scarp, or to fire on the enemy in the moat, or in the covert-way.

BANTAM-WORK, a kind of Indian painting, and carving on wood, resembling Japan work, only more gay, and decorated with a great variety of gaudy colours.

BAPTISM, in theology, the ceremony of washing; or a sacrament whereby a person is admitted into the Christian church.

The word is formed from the Greek, βαπτίζω, of βαπτο, to dip, or wash.

In the primitive Christian church, the office of baptizing was vested principally in the bishops, and priests, or pastors of the respective parishes: but, with the consent of the bishop, it was allowed to the deacons, and, in cases of necessity, even to laymen, to baptize; but never, under any necessity whatever, was it permitted to women to perform this office. Nor was it enough, that baptism was conferred by a person called to the ministry, unless he was also orthodox in the faith. This became matter of great bustle in the church; and hence arose the famous controversy between Cyprian and Stephen bishop of Rome, concerning the re-baptizing those who had been baptized by heretics, Cyprian asserting that they ought to be re-baptized, and Stephen maintaining the contrary opinion.

BAPTISMAL, something belonging to baptism; thus we say, baptismal vow, fonts, presents, &c.

BAPTISTS, in church history, the name by

which the anabaptists love to distinguish themselves. See ANABAPTISTS.

BAPTISTERY, the place, in which the ceremony of baptism is performed.

BAR, in a general sense, denotes a slender piece of wood or iron for keeping things close together.

BAR, in courts of justice, an inclosure made with a strong partition of timber, where the council are placed to plead causes. It is also applied to the benches where the lawyers or advocates are seated, because anciently there was a bar to separate the pleaders from the attorneys, and others. Hence our lawyers who are called to the bar, or licensed to plead, are termed barristers, an appellation equivalent to 'licentiate in other countries.

BAR, in law, a plea of a defendant which is said to be sufficient to destroy the plaintiff's action.

BAR, in heraldry, an ordinary resembling the fess, but much smaller.

It differs from the fess only in its narrowness. The fess is also confined to a single place, whereas the bar may be placed in any part of the shield.

BAR, in horsemanship, implies the highest part of a horse's mouth, between the grinders and tusks, that part only which lies under and at the side of the bars, retaining the name of gum.

BAR, in music, a stroke drawn perpendicularly across the lines of a piece of music, including, between every two bars, a certain quantity, or measure of time, which is different, according as the music is either triple or common. In the former the measure of three crotchets is included, in the latter four. The principal use of bars is to regulate the beating of time.

BAR, in hydrography, a shoal, or bank of sand, gravel, &c. situated at the mouth of a river or harbour, which frequently endangers, and sometimes totally prevents the navigation.

BARs of a Capstan; see the article CAPSTAN.

BAR-MASTER, among miners, the person who keeps the dish, or gage, for measuring the ores.

BAR-SHOT. See SHOT.

BARACKS. See BARRACKS.

BARALIPTON, among logicians, the first indirect mode of the first figure of a syllogism.

When the two propositions are general, and the third particular, the middle term being the subject in the first proposition, and the predicate in the second, the syllogism is said to be in baralipon. The following is of this kind:

B A. Every evil ought to be feared;

R A. Every violent passion is an evil;

LIP. Therefore something that ought to be feared is a violent passion.

BARA-

BAR

BARALOTTS, *Baralotti*, a sect of heretics at Bologna in Italy, among whom all things, even their wives and children, were in common. They were also called *obedients*, or compliers, because they readily complied with every thing that tended to promote debauchery.

BARBA *Jovis*, Jupiter's beard, in botany, (or the silver-bush, so called from the whiteness of its leaves) is a shrub which often grows ten or twelve feet high, and divides into many lateral branches, which are furnished with winged leaves, composed of an equal number of narrow lobes, which are very white and hairy. The flowers, which are papilionaceous, are produced at the extremity of the branches, collected into small heads, of a bright yellow colour, and appear in June; these are succeeded by short woolly pods, containing two or three kidney-shaped seeds. This plant is increased by seeds or cuttings; but being somewhat tender, it requires shelter in winter in this climate.

BARBACAN, or **BARBICAN**, properly signifies the outer wall, or exterior defence of a city or fortress.

BARBACAN also implies a fort at the entrance of a bridge, or in the out-fort of a city, having a double wall with towers.

It likewise denotes an aperture made in the walls of a fortress, to fire through upon the enemy.

BARBACAN, in architecture, is a canal or opening left in the wall, in order to give room for the water to run in and out, when buildings are erected in places liable to be overflowed, &c.

BARBADOES-TAR, *Petroleum Barbadosense*, in the materia medica, a fluid bitumen, or mineral oil, of a reddish colour, and thick consistence, approaching to that of treacle, or common tar. It is found in several of our American dominions, especially in that island from which it receives its name.

This bitumen is greatly esteemed by the Americans as a sudorific, and frequently given in disorders of the breast. It is also used as an external discutient and antiparalytic.

BARBARA, in logic, is a name given by the schoolmen to the first mode of the first figure of syllogisms.

A syllogism in *barbara* is that whose propositions are all universal and affirmative; the middle term being the subject of the first proposition, and the attribute in the second: as,

BAR. Every wicked man is miserable;

B A. All tyrants are wicked men;

R A. Therefore all tyrants are miserable.

BARBARISM, in grammar, an offence against the purity of style or language; or a hard and coarse expression, never used by polite authors.

BARBE, a name usually given to a Barbary

BAR

horse, greatly esteemed for its beauty and swiftness.

BARBE, in the military art, is a term applied to the firing of cannon. Thus, to fire in *barbe*, is to fire the cannon over the parapet, instead of firing through the embrasures. The parapet must not be above three feet and a half high, otherwise it will be impossible to fire in this manner.

BARBE, among our ancestors, signified the armour of a knight's horse.

BARBEL, *Barbus*, the name of a river fish, and so called from its having a barb or beard under its nose.

BARBERY, in botany; see **BERBERIS**.

BARBLES, or **BARBS**, in farriery, are small excrescences under the tongue, and which may be discovered by drawing it aside, and cured by cutting them close off, and washing the part with brandy, or salt and water.

BARCALAO, a species of cod resembling that of Newfoundland, caught in several parts of the South-sea, particularly on the coast of the island of Juan Fernandes.

BARCA-LONGA, a small coasting vessel, navigated on the coast of Spain: it is equipped with two, and sometimes three pole-masts, i. e. masts that have no top-mast or upper-part, and long square sails, called lug-sails.

BARD, a poet among the ancient Gauls and Britons, who sung the praises of heroes, in order to recommend virtue, and compose the dissensions among mankind.

BARDNA, in botany. See **ARCTIUM**.

BARDESANITES, in ecclesiastical history, a sect of heretics in the second century, the followers of Bardesanes, a native of Edessa, in Mesopotamia.

They held the devil to be a self-existent independent Being; and taught that Christ was not born of a woman, but brought his body with him from heaven; maintained that God himself was subject to fate; and that virtue and vice depended on the influence of the stars.

BARGAIN, in commerce, a contract or agreement in buying and selling.

BARGAIN and Sale, in law, is properly a contract, made of manors, lands, and other things, transferring the property thereof from the bargainer to the bargainee, for a consideration in money.

BARGE, in the marine, a vessel or boat of state, curiously decorated, furnished with elegant apartments, canopies, and cushions, equipped with a band of rowers, and adorned with flags and streamers: they are generally used for processions on the water by noblemen, officers of state, or magistrates of great cities. Of this kind we may with great probability suppose the famous barge or

galley.

BAR

galley of Cleopatra, so elegantly painted by Shakespeare, which, as it is so closely connected with our subject, that is, so beautifully illustrated by it, we shall partly insert :

The barge the fat in, like a burnished throne,
Burnt on the water ; the poop was beaten gold,
Purple her sails, and so perfum'd, that
The winds were love-sick with 'em ; the oars
were silver,

Which to the tune of flutes kept stroke, and made
The water which they beat, to follow faster,
As amorous of their strokes

. on each side her
Stood pretty dimpled boys, like smiling Cupids,
With divers-colour'd fans, whose wind did seem
To glow the delicate cheeks which they did cool,
And what they undid, did

. At the helm
A seeming mermaid steer'd : the silken tackles
Swell'd with the touches of those flower-soft hands
That yarely fram'd their office. From the barge
A strange invisible perfume hit the sense
Of the adjacent wharfs.

There are likewise other barges of a smaller kind and a lighter frame, for admirals and captains of ships of war, calculated to be easily hoisted into and out of the ships to which they may belong.

BARGES are also large flat-bottomed vessels of burthen, for lading and discharging ships, and removing their cargoes in a harbour. See LIGHTER, PRAME, KEEL.

BARGE-COUPLES, in architecture, a beam mortised into another, to strengthen the building.

BARGE-COURSE, with bricklayers, implies that part of the tiling which projects over without the principal rafters, in all sorts of buildings where there is either a gable-end, or a kirkin-head.

BARILLA, a species of pot-ash, sometimes called soda, and prepared in Spain from a plant called kali. See KALI.

BARING of Trees, in agriculture. See ABLAQUEATION.

BARK, *Cortex*, the exterior part of trees, serving them for a skin or covering. There are two barks belonging to every tree, the outward one, called *cortex*, and the inward one, called *liber* ; which latter, being placed between the outward bark and the wood, comes nearest to the nature of the wood, and in time passes into it, by a successive mutation of the *cortex* into *liber*, and the *liber* into wood. The outward bark is generally of a spongy texture, and communicates with the pith by a multiplicity of small fibres, passing through the capillary tubes of which the wood consists ; so that the roots having imbibed the proper nourishment

BAR

of the tree, it is carried up by the warmth of the sun, through the fine arterial vessels of the tree, to the top of it, and being there condensed by the cold, it does, by its own gravity, return down by the vessels which lie between the wood and the inner bark, which perform the office of veins, and as it passes by, leaves such parts of its juice as the texture of the bark will receive, and requires for its support.

The bark serves for divers purposes ; for it not only transmits the nutritious juices of the plants, but also contains divers fat oily humours, to defend the inner parts from the injuries of the weather. As animals are furnished with a *panniculus adiposus*, usually replete with fat, which invests and covers all the fleshy parts, and screens them from external cold ; so are plants encompassed with a bark replete with fat juices, by means whereof the cold is kept out, and in winter time, the spiculae of ice prevented from fixing and freezing the juices in their vessels ; whence it is, that some sort of trees remain ever-green throughout the year, by reason their barks are more compact, and contain a larger quantity of oil than can be spent and exhaled by the sun. The ancients wrote their books on bark, especially of the ash or lime-tree, not on the exterior, but on the inner and finer bark.

There are many kinds of barks in use in several arts ; as the oak-bark for tanning leather, which when it has done that office, is fit for use in hot-houses, &c. and also for firing. Some barks are used in medicine, as the jesuit's-bark, mace, &c. and others for divers purposes, as the bark of the cork-tree : in the East-Indies, they spin the bark of a certain tree into a stuff ; they likewise mix it with silk in manufacturing of stuffs which go under different denominations.

Jesuits BARK. See the article QUINQUINA.

BARK, in the marine, a general name given to small ships : it is however peculiarly appropriated to those that carry three masts and no mizen-top-sail. Our northern seamen who navigate the colliers, give this distinction to a broad-sterned ship which carries no ornamental figure on the stern, or prow.

BARKING of Trees, the peeling off the rind or bark.

It is necessary in our climate, to perform this operation in the month of May ; because in that month the bark will more readily separate from the wood, than at any other time of the year.

BARLEY, *Hordeum*, in botany, a gramineous, frumentaceous plant, whose seeds are of the larger sort, covered with a husk growing in a spike, and the grains bearded. Barley, properly dried into malt and ground, makes a principal ingredient in that well known liquor called beer and ale, for which purpose it is greatly propagated in England.

The

The culture of barley is to sow the seed in the spring of the year; if the land is light and dry, the beginning of March is the proper season; but in strong clayey soils, it should not be sown till April, and sometimes not till the beginning of May; but when it is sown so late, it requires a favourable autumn to get it well in. Some sow barley upon land where wheat grew the former year; but when this is practised, the ground should be ploughed the beginning of October, in a dry time, laying it in small ridges, that the frost may mellow it the better, and this will much improve the land; and if it is ploughed again in January or February, it will still be more advantageous: in March the ground should be ploughed again and laid flat, where it is not very wet; but in strong wet lands the ground should be laid rounding, and the furrows made deep to receive the water. When this is finished, the common method is to sow the seed with a broad cast, at two sowings; the first being harrowed in once, and the second harrowed until the seed is buried. The common allowance of seed is four bushels to an acre: this is the quantity of grain usually sown by the farmers; but if they could be prevailed on to alter this practice, they would soon find their account in it, for if less than half that quantity were sown, there would be a greater produce, and the corn less liable to lodge (which has been proved by experience); for when corn, or any other vegetables, stand very close to each other, the stalks are drawn up very weak, and are therefore incapable to resist the force of the winds, or bear up under heavy rains; but when they are at a proper distance, their stalks will be more than twice the size of the others, and consequently must support themselves with more strength; for the natural growth of corn is to send out many stalks from a root, and not rise so much in height, therefore it is entirely owing to the roots standing too near each other, that the stalks are drawn up tall and weak. When barley is sown, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth, which will render it better to mow, and cause the earth to lie closer to the roots, which will be of great service to it in dry weather. Where barley is to be sown upon new broken-up land, the usual method is to plough it up in March, and let it lay fallow until June; at which time it should be ploughed again and sown with turnips, which are eaten by sheep in winter, by whose dung the land is greatly enriched: in March following the ground is ploughed again, and sown with barley, as before directed. There are many people who sow clover with their barley, and some have sown lucern; but neither of these methods is to be commended, for where there is a good crop of barley, the clover or lucern must be so weak as not to pay for standing; so that the better way is, to sow barley without

any other crop among it, for when the barley is taken off the ground, the land will be at liberty to receive any other crop.

The practice of sowing clover, rye-grass, and other grass seeds with corn, has been so long and universally established among farmers, that there is little hopes of prevailing with those people to alter a custom which has been handed down to them from their predecessors, although there may be many examples produced to shew the absurdity of this practice.

When barley has been up three weeks or a month, it is not amiss to roll it over with a weighty roller, which will press the earth close to the roots, and thereby prevent the sun and air from penetrating the ground, which will be of singular service in dry seasons, particularly where the land is light; and this rolling of it before it stalks, will cause the roots to produce a greater number of stems; so that if the plants should be thin, this operation will make them spread so as to fill the ground, and likewise strengthen the stalks.

Barley is fit to cut when the red colour of the ears is off, the stalks turn yellow, and the ears begin to hang down. In the north of England they always reap their barley, and make it up in sheaves, as is practised for wheat, by which method it becomes more handy for stacking, and less corn is wasted than by the common way of mowing it; but it cannot be so well practised where there are many weeds among the corn, especially in moist seasons; for when it so happens, the barley must lay in the swarth till all the weeds are dead; and if it should be wet weather, it must be shook up, and turned every dry day after rain, to prevent its sprouting. When it is carried to be stacked, it should be thoroughly dry; for if it be stacked wet, it will turn musty; or if too green, it is subject to burn in the mow: to prevent which, the best method is to cut a hole from top to bottom in the middle of the mow; or if it is suspected before stacking, to lay in the middle some trusses of straw, at the time of building the mow, which can be readily removed if it is likely to fire. The common produce of barley is two and a half, or three quarters on an acre.

Common English barley is seldom or never used medicinally: besides its nutritive virtues, in which it agrees with all other grain of the like kind, it is reckoned to have somewhat more absterive in it; for which reason, those who are not accustomed to eat barley bread, (of which it makes the worst sort) will find it at first to operate with them like a gentle cathartic. It is very probable, that a change from a finer and more nourishing bread to this, would in many corpulent constitutions be of great service, by reducing their exorbitant bulks, and cleansing the secretory passages.

BARLEY-CORN, the least long-measure known
in

in England: it is equal to one third of an inch.

BARNABITES, in ecclesiastical history, a religious order founded in the sixteenth century by three Italian gentlemen, who had been advised by a famous preacher of those days, to read carefully the epistles of St. Paul; and hence they were styled clerks of St. Paul; but acquired the name of Barnabites, from their performing their first exercise in the church of St. Barnabas at Milan. Their habit is black, and their duty consists in instructing, catechising, and serving in mission.

BARNICLE, or inland goose, in natural history, a species of goose with a black beak, which is much shorter than that of the common goose. It is common in the north of Scotland.

BARNICLE also signifies a species of shell-fish, often found sticking to the bottoms of ships, rocks, &c.

BARNICLES, among farriers, an instrument composed of two branches, joined at one of the extremities with a hinge. It is put upon the nose of a horse, when he will not otherwise stand quiet to be shod, blooded, or dressed.

BAROCO, in logic, implies the fourth mode of the second figure of syllogisms.

A syllogism in baroco has the first proposition universal and affirmative; but the second and third, particular and negative; while the middle term is the predicate in the two first propositions. The following is of this kind:

B A. Every virtue is attended with discretion:

r o. Some kinds of zeal are not attended with discretion;

c o. Therefore some kinds of zeal are not virtues.

BAROMETER, an instrument with which we find the weight and variations of the atmosphere, in order to determine the changes of the weather.

In the beginning of the last century, it was a prevailing opinion among philosophers, that the universe was full of matter; and that Nature (as they expressed it) abhorred a vacuum: accordingly they imagined, that if a fluid was sucked up a pipe with a sufficient force, it would rise to any height whatever; since Nature would not suffer any part of the pipe to remain empty. Galileo, who flourished about that time, found upon trial, that the common pump would not raise water, unless the sucker reached within three and thirty feet of its surface in the well: from hence he judiciously inferred, that a column of water thirty-three feet high was a counterpoise to a column of air of an equal base, whose height extended to the top of the atmosphere; and that, for this reason, the water would not follow the sucker any farther. Torri-

celli, observing this, took the hint; and considered, that if a column of water of about thirty-three feet, was equal in weight to a column of air of the same base; a column of mercury, no longer than about twenty-nine inches and a half, would be so too; such a column of mercury being as heavy as thirty-three feet of water. Accordingly he tried the experiment in a glass-tube, and found it to succeed. The apparatus he made use of is now the common barometer, or weather-glass.

The mercury standing at a less height, the nearer it is carried to the top of the atmosphere, renders it useful in determining the height of mountains, and finding out the different elevation of one place above another. Accordingly, Dr. Halley has given a table for that purpose, in the Philosophical Transactions, N^o. 181, shewing how many feet the descent of the mercury each inch answers to, as it is conveyed to the top of a mountain, or other elevated place. And Dr. Nettleton has done the like in the Philosophical Transactions, N^o. 388, shewing what number of feet answers to each tenth part of an inch, from twenty-six to thirty-one inches of mercury.

But the principal use of it is, to estimate the gravity of the air at different times, in order to foresee the alterations of the weather, which are consequent thereon. To this end, Dr. Halley in the same transaction has also laid down the more remarkable phenomena, relating to the different heights of the mercury at different times, together with the solution of each; which are so just, and so agreeable to true philosophy, that we doubt not but the reader will excuse us for giving his account in his own words, rather than to render it imperfect, by endeavouring to vary from it, or abridge it.

“ 1. In calm weather, when the air is inclined to rain, the mercury is commonly low.

“ 2. In serene, good, settled weather, the mercury is generally high.

“ 3. Upon very great winds, though they be not accompanied with rain, the mercury sinks lowest of all, with relation to the point of the compass the wind blows upon.

“ 4. Ceteris paribus, the greatest heights of the mercury are found upon easterly and north-easterly winds.

“ 5. In calm frosty weather, the mercury generally stands high.

“ 6. After very great storms of wind, when the mercury has been low, it generally rises again very fast.

“ 7. The more northerly places have greater alterations of the barometer, than the more southerly.

“ 8. Within the tropics, and near them, those accounts we have had from others, and my own observations at St. Helena, make very little or

" no variation of the height of the mercury in all weathers.

" Hence I conceive that the principal cause of the rise and fall of the mercury, is from the variable winds, which are found in the temperate zone, and whose great inconstancy, here in England, is most notorious.

" A second cause is the uncertain exhalation and precipitation of the vapours lodging in the air, whereby it comes to be at one time much more crowded than at another, and consequently heavier, but this latter in a great measure depends upon the former. Now, from these principles, I shall endeavour to explicate the several phenomena of the barometer, taking them in the same order I laid them down. Thus:

" 1. The mercury's being low, inclines it to rain, because the air being light, the vapours are no longer supported thereby, being become specifically heavier than the medium wherein they floated, so that they descend towards the earth, and in their fall, meeting with other aqueous particles, they incorporate together, and form little drops of rain; but the mercury's being at one time lower than at another, is the effect of two contrary winds blowing from the place where the barometer stands, whereby the air of that place is carried both ways from it, and, consequently, the incumbent cylinder of air is diminished, and accordingly the mercury sinks: as for instance, if in the German ocean it should blow a gale of westerly wind, and at the same time an easterly wind in the Irish sea; or if in France it should blow a northerly wind, and in Scotland a southerly; it must be granted, that that part of the atmosphere impendent over England, would thereby be exhausted and attenuated, and the mercury would subside, and the vapours, which before floated in those parts of the air of equal gravity with themselves, would sink to the earth.

" 2. The greater height of the barometer is occasioned by two contrary winds blowing towards the place of observation, whereby the air of other places is brought thither and accumulated; so that the incumbent cylinder of air, being increased both in height and weight, the mercury pressed thereby must needs stand high, as long as the winds continue so to blow; and then the air, being specifically heavier, the vapours are better kept suspended, so that they have no inclination to precipitate and fall down in drops, which is the reason of the serene good weather which attends the greater heights of the mercury.

" 3. The mercury sinks the lowest of all by the very rapid motion of the air in storms of wind. For the tract or region of the earth's surface, wherein the winds rage, not extending all

" round the globe, that stagnant air which is left behind, as likewise that on the sides, cannot come in so fast as to supply the evacuation made by so swift a current, so that the air must necessarily be attenuated, when and where the said winds continue to blow, and that more or less, according to their violence; add to which, that the horizontal motion of the air being so quick as it is, may, in all probability, take off some part of the perpendicular pressure thereof; and the great agitation of its particles is the reason why the vapours are dissipated, and do not condense into drops, so as to form rain, otherwise the natural consequence of the air's rarefaction.

" 4. The mercury stands the highest upon the easterly and north-easterly wind, because in the great Atlantic ocean, on this side the thirty-fifth degree of north latitude, the winds are almost always westerly or south-westerly; so that whenever here the winds come up at east and north-east, 'tis sure to be checked by a contrary gale as soon as it reaches the ocean; wherefore, according to what is made out in our second remark, the air must needs be heaped over this island, and consequently the mercury must stand high, as often as these winds blow. This holds true in this country, but is not a general rule for others, where the winds are under different circumstances; and I have sometimes seen the mercury here as low as twenty-nine inches upon an easterly wind, but then it blew exceeding hard, and so comes to be accounted for, by what was observed upon the third remark.

" 5. In calm frosty weather the mercury generally stands high, because (as I conceive) it seldom freezes, but when the winds come out of the northern or north-eastern quarters; or, at least, unless those winds blow at no great distance off: for the north parts of Germany, Denmark, Sweden, Norway, and all that tract from whence the north-eastern winds come, are subject to almost continual frost all the winter; and thereby the lower air is very much condensed, and in that state is brought thitherwards by those winds, and being accumulated by the opposition of the westerly wind blowing in the Ocean, the mercury must needs be pressed to a more than ordinary height; and, as a concurring cause, the shrinking of the lower parts of the air into lesser room by cold, must needs cause a descent of the upper parts of the atmosphere, to reduce the cavity made by this contraction to an equilibrium.

" 6. After great storms, when the mercury has been very low, it generally rises again very fast: I once observed it to rise one inch and an half in less than six hours, after a long-continued storm

“ form of south-west wind. The reason is, because the air being very much rarefied, by the great evacuations which such continued storms make thereof, the neighbouring air runs in the more swiftly, to bring it to an equilibrium; as we see water runs the faster for having a greater declivity.

“ 7. The variations are greater in the more northerly places, as at Stockholm, greater than that at Paris (compared by M. Pafchal;) because the more northerly parts have usually greater storms of wind than the more southerly, whereby the mercury should sink lower in that extreme; and then the northerly winds bringing the more dense and ponderous air from the neighbourhood of the Pole, and that again being checked by a southerly wind at no great distance, and so heaped, must of necessity make the mercury in such case stand higher in the other extreme.

“ 8. Lastly, this remark, That there is little or no variation near the equinoctial, does above all others confirm the hypothesis of the variable winds being the cause of these variations of the height of the mercury; for in the places above-named there is always an easy gale of wind blowing nearly upon the same point, viz. east-north-east, at Barbadoes, and east-south-east at St. Helena, so that there being no contrary currents of air to exhaust or accumulate it, the atmosphere continues much in the same state: however, upon hurricanes (the most violent of storms) the mercury has been observed very low, but this is but once in two or three years, and it soon recovers its settled state, about $29\frac{1}{2}$ inches.”

Monfieur Leibnitz accounted for the descent of the mercury before rain, upon another principle, viz. as a body specifically lighter than a fluid, while it is suspended by it, adds more weight to that fluid, than when, by being reduced in its bulk, it becomes specifically heavier, and descends; so the vapour, after it is reduced into the form of clouds, and descends, adds less weight to the air than before; and therefore the mercury falls. To which it is answered, 1st, That when a body descends in a fluid, its motion in a very little time becomes uniform, (or nearly so) a farther acceleration of it being prevented by the resistance of the fluid; and then, by the third law of nature, it presses the fluid, downwards, with a force equal to that whereby it tends to be farther accelerated, that is, with a force equal to its whole weight. 2dly, The mercury, by its descent, foretels rain a much longer time before it comes, than the vapour, after it is condensed into clouds, can be supposed to take up in falling. 3dly, Supposing that as many vapours as fall in rain, during the space of a whole year, were at once to be condensed into clouds, and even quite

cease to gravitate upon the air, its gravity would scarce be diminished thereby, so much as is equivalent to the descent of two inches of mercury in the barometer. Farther, in many places between the tropics, the rains fall at certain seasons, in very great quantities, and yet the barometer shews there very little or no alteration in the weight of the air.

The following are Mr. Patrick's observations on the rising and falling of the mercury. They are very just, and are to be accounted for on the same principles with those of Dr. Halley.

“ 1. The rising of the mercury prefaces in general fair weather; and its falling, foul weather; as rain, snow, high winds, and storms.

“ 2. In very hot weather, the falling of the mercury foreshews thunder.

“ 3. In winter the rising prefaces frost; and in frosty weather, if the mercury falls three or four divisions, there will certainly follow a thaw. But in a continued frost, if the mercury rises, it will certainly snow.

“ 4. When foul weather happens soon after the falling of the mercury, expect but little of it. And, on the contrary, expect but little fair weather, when it proves fair shortly after the mercury has risen.

“ 5. In foul weather, when the mercury rises much and high, and so continues for two or three days before the foul weather is quite over, then expect a continuance of fair weather to follow.

“ 6. In fair weather, when the mercury falls much and low, and thus continues for two or three days before the rain comes; then expect a great deal of wet, and probably high winds.

“ 7. The unsettled motion of the mercury denotes uncertain and changeable weather.

“ 8. You are not so strictly to observe the words engraven on the plates (though, for the most part, it will agree with them) as the mercury's rising and falling: for if it stands at much rain, and then rises up to changeable, it prefaces fair weather, although not to continue so long, as it would have done, if the mercury were higher: and so, on the contrary, if the mercury stood at fair, and falls to changeable, it prefaces foul weather; though not so much of it, as if it had sunk down lower.”

From these observations, it appears, that it is not so much the height of the mercury in the tube that indicates the weather, as the motion of it up and down; wherefore, in order to pass a right judgment of what weather is to be expected, we ought to know whether the mercury is actually rising or falling, to which end, the following rules are of use.

1. If the surface of the mercury is convex, standing higher in the middle of the tube than at the sides,

BAR

sides, it is generally a sign that the mercury is then rising.

2. If the surface is concave, or hollow in the middle, it is sinking. And,

3. If it is plain, the mercury is stationary, or rather, if it is a little convex; for mercury being put into a glass tube, especially a small one, will naturally have its surface a little convex; because the particles of mercury attract each other more forcibly than they are attracted by glass. Farther,

4. If the glass is small, shake the tube; and if the air is growing heavier, the mercury will rise about half the tenth of an inch higher than it stood before; if it is growing lighter, it will sink as much. This proceeds from the mercury's sticking to the sides of the tube, which prevents the free motion of it, till it is disengaged by the shock. And therefore, when an observation is to be made with such a tube, it ought always to be shaken first, for sometimes the mercury will not vary of its own accord, till the weather it ought to have indicated, is present.

The usefulness of knowing, whether the mercury is actually rising or falling; and the advantage that would arise from perceiving the most minute variations in estimating the heights of places, have given occasion to the invention of several kinds of barometers different from the Torricellian, though founded on the same principle; wherein the scale of variation, which in that is not above three inches, should be considerably larger. Of which we are now to give some account.

1. The first is that of Des Cartes, which was made in the form represented, Plate XVIII. *fig. 1.* where AB is a tube hermetically sealed at A, and having its lower orifice immersed in stagnant mercury EF, and filled with the same fluid to G, from thence to H with water, and empty from thence to the top. Now, when the mercury rises in this tube, suppose from G to L, the water will be raised in the small tube perhaps from H to M, viz. as many times further, as the tube CA is smaller than CD; by which means the variations become much more sensible, than they are in the common barometer. The inconvenience of this was, that the air, included in the water, getting loose by degrees, filled the void space at the top, and spoiled the machine.

2. He then contrived it thus: ABC, (*fig. 2.*) is a bent tube hermetically sealed at A, filled with water from F to D (tinged with aqua regia to prevent its freezing,) from D to E with mercury, and empty from thence to the top. Then, upon the mercury's rising, suppose from E to M, and falling as much at D, the surface of the water at F would sink so many times farther than the surface of the mercury at D, as the tube CG was smaller than GH. The water here is liable to eva-

BAR

porate, though that may, in some measure, be prevented, by pouring a few drops of oil of sweet almonds upon it. Others have contrived

3. The horizontal or rectangular barometer (*fig. 3.*) hermetically sealed at A, and filled with the mercury from D to E; then as the upper surface of it rises in the tube, suppose from E to F, the lower will be driven from D to G, as many times farther, as this part of the tube is less than that at E. But it often happens, that some parts of the mercury break off from the rest in the leg BC, and are left behind. This inconvenience is remedied in,

4. The diagonal barometer ABC (*fig. 4.*) wherein the mercury, instead of rising from B to D (suppose that space to correspond to the scale of variation in a strait tube) will rise from B to A; for it will always stand at the same perpendicular height, whatever be the inclination of the tube; because fluids press only according to their perpendicular altitude. But the tube AB must not be too much inclined, lest the mercury break in it, as in the former.

5. AB (*fig. 5.*) is Dr. Rook's wheel-barometer, wherein ABD is a tube filled with mercury from a to E; a is an iron ball, swimming on the surface of the mercury; this as it subsides with the surface of the mercury, draws the little wheel mn round, to whose circumference it is fixed by means of the string ac: this wheel carries the index PQ, which points to the graduated edge of the circle KL, and by its motion shews the most minute variations of the mercury. When the ball a is raised by the mercury on which it swims, the index is drawn the contrary way by a lesser ball b, which hangs on the other side the wheel. The friction in this machine, unless it be made with great accuracy indeed, renders it useless.

6. The pendent barometer is another contrivance to render the variations more sensible. It consists of a small conical tube, (represented *fig. 6.*) hermetically sealed at A, and filled with mercury from C to D, and empty from thence to A. Now, supposing the gravity of the air encreased, it will raise the mercury higher in the tube, and so force it into a narrower part; by which means the column becoming longer, its perpendicular pressure upon the air below will be proportionably encreased. On the contrary, when the air becomes lighter, the mercury descends into a larger part of the tube, and by that means has the length of its column proportionably contracted. The inconvenience that attends this barometer is, that the tube must be very small, otherwise the mercury will fall out; or the air will be apt to get into it, and divide the column in several places; and when the tube is very small, the friction of the mercury against the sides of it, will hinder it from rising and falling freely.

BAR

7. Dr. Hook, observing how unfit the common barometer was to be used on board of ship, by reason its position ought to be steady, contrived the following one, called, from its use, a marine barometer, consisting of two parts, the one AB (*fig. 7.*) the common spirit thermometer, the other CD (*fig. 8.*) a tube filled with air from C to E, and from thence to the end D with tinged water. This end is immersed in the same fluid contained in the vessel GF; and having its surface exposed to the pressure of the external air. Now, the last of these machines will be affected both by the warmth of the external air, and also by its pressure: the former dilating the air included in CE, and by that means driving the water downwards; the latter pressing it up higher in the tube: whereas the other, viz. AB, is affected by the warmth of the air alone. Consequently, were these instruments graduated in such a manner, that, if the gravity of the external air should always remain the same it was when the instruments were made, their variations (then only depending on its warmth) should exactly correspond with each other; that is, when the spirit in the tube AB, should ascend to 1, the water in CD, should descend to 1, &c. Then, whenever their variations should be observed to differ from each other, the difference could only be ascribed to some alteration in the pressure of the air upon the surface of the water in the vessel GF. In proportion therefore as this difference is greater, or less, so is the alteration in the gravity of the air, from what it was when the instruments were adjusted. For instance, when the water stands above the division which corresponds to that which the spirit points to in the other machine, it is an indication, that the pressure of the air is greater at that time, than when the instruments were graduated, and *vice versa*.

This machine is not only more useful at sea, than the common one, as not requiring a steady position; but may have its scale of variation considerably enlarged, by making the bore of the tube CD very small, in proportion to the capacity of its head C.

But it is observed, that in long keeping this instrument, the included air loses somewhat of its elasticity; whereby, in process of time, the water stands higher than it ought, and therefore indicates the gravity of the air to be greater than what it is.

The *Compound BAROMETER*, as invented by Mr. Rowning, is represented by Plate XVIII. *fig. 9.* hermetically sealed at A, and open at C, being empty from A to D, filled with mercury from thence to B, and from B to E, with water. Let GBH be a horizontal line, then it is plain from the nature of the syphon, that all the compound

BAR

fluid contained in the part from H to G, will be always in equilibrio with itself, be the weight of air what it will; because the pressure at H and G must be equal: whence it is evident that the column of mercury DH is in equilibrio with the column of water GE, and a column of air of the same base conjointly, and will therefore vary with the sum of the variations of each of these.—The great property of this barometer is, that the scale of variation may be increased at pleasure.

But of all the barometers above described there is none equal to the common one, which is made in the following manner: Having filled a glass tube with quicksilver, and covered the orifice with your finger and inverted it, and immersed the finger in a vessel of quicksilver; upon drawing the finger from the orifice, the quicksilver will never wholly subside. If the tube be long enough, it will subside in part, till it rests at a certain altitude, generally between 31 and 28 inches; but if the tube be shorter than that altitude called the standard, it will not subside at all: due care must be taken in filling the tube to expel all the air-bubbles that adhere to the inside of the tube, which may be done by putting a slender wire in the tube, and stirring it up and down; or if the tube and quicksilver be very clean, which they ought to be, you may effect it by leaving about an inch or less of the tube unfilled, and then putting your finger on the orifice, and inverting it gently, that the air in the vacant part may ascend gradually along the tube, and sweep up the little air-bubbles along with it; and lastly, by inverting it gradually to its former position, and filling it up with quicksilver.

In this last method care must be taken not to let the large air-bubble ascend too quick, lest by its rushing against the crown of the tube with violence it should break it. Also in emptying the tube, for fear of the same accident, take care first to incline it; then to draw the orifice gently above the surface of the stagnant quicksilver, and immediately immerse it again, so as to take in but little air at a time. This is the method of making barometers, which will be complete when placed in a frame, having at the side a scale of three inches divided into tenths, with a nonius dividing each said division into ten more, and placed at the height of twenty-eight inches above the surface of the quicksilver in the basin. The weather-glass complete is represented by Plate XVIII. *fig. 10.* containing the barometer, thermometer, and hygrometer. See THERMOMETER and HYGROMETER.

Mr. Cummins, an ingenious clock-maker in London, has lately invented a clock-barometer, or a clock that gives the height of the mercury in the barometer, for a certain time past; whereby we apprehend, that he pretends to know the resist-

ance

ance any mechanical body as a pendulum, &c. might have, in any intermediate space, from the different densities of the air. But if this is the case, we are assured that artists trusting to this curious machine alone, will find themselves deceived; for the true density of the air cannot be discovered from the height of the barometer singly, but is compounded of the height of the barometer and thermometer jointly.

Doctor Bradley was very elaborate in making observations for finding the true density of the air, and, after some years labour, constructed the following rule, which he found never erred, viz.

Divide the height of the barometer expressed in tenths of inches, by 350 + the degrees of the height of Fahrenheit's thermometer, and the quotient will give a number that will be in proportion to the mean density of the air. The mean density of the air may be expressed by $\frac{296}{350+50} + .74$.

For example; Suppose the height of the barometer 30.2, and the thermometer 60°, then will $\frac{30 \times 10 + 2}{350 + 60} = .736$, &c. express the proportion

of the density of the air (at the time the barometer and thermometer have the above altitudes of the mercury) to the mean density. But again, suppose the height of the mercury in the barometer the same as before, viz. 30.2, and the thermometer = 30 degrees; then will $\frac{30 \times 10 + 2}{350 + 30} = .794$, &c. be the proportion

of the density of the air to the mean state, which plainly shews that the height of the barometer singly will not give the true density of the air; for the height of the barometer is the same in each example; and yet from the variation of the thermometer, the true density differs in proportion from the mean density .74, as the above numbers .736, &c. and .794, &c. differ in proportion from the number .74.

BARON, the next degree of nobility below a viscount and above a baronet.

BARONS of the Exchequer, the four judges to whom the administration of justice is committed, in matters relating to the revenues of the crown.

They were formerly barons of the realm; but are generally of late persons learned in the law. They are obliged by their office to inspect the king's accounts, and accordingly have auditors under them.

BARONS of the Cinque Ports, are the members of the house of commons sent by the Cinque ports. See CINQUE PORTS.

BARON AND FEME, a term used in our law to signify the husband in relation to his wife, who is

called feme. They are considered only as one person, so that a husband cannot be witness for or against his wife, nor the wife for or against her husband, except in cases of high treason.

BARON AND FEME, in heraldry, is when the coats of arms of a person and his wife are borne per pale in the same escutcheon, the man's being always on the dexter, and the woman's on the sinister side: but if the woman be an heiress, her coat must be borne by the husband on an escutcheon of pretence.

BARONET, a modern degree of honour, next to a baron, created by king James I. in order to settle a plantation in Ulster, for which purpose each was to maintain thirty soldiers in Ireland for three years, after the rate of eight-pence sterling per day to each soldier.

This honour is hereditary, and they have the precedence of all knights, except those of the garter, bannerets, and privy counsellors.

BARONY, the honour and territory which gives title to a baron, whether he be a layman or a bishop.

BAROSCOPE, the same with barometer. See BAROMETER.

The word is formed from βαρῦς, weight, and σκοπεῖν, to view.

BARR. See BAR.

BARRACAN, in commerce, a sort of stuff resembling camlet, but of a coarser grain.

BARRACKS, or BARACKS, places erected for soldiers to lodge in, especially in garisons.

BARRATOR, in law, a common mover or maintainer of suits and quarrels, either in courts, or elsewhere.

Lambert derives the word from the Latin, *barathra*, or *bulatra*, a vile knave.

BARRATRY, in the marine acceptance, implies a defrauding the owners by the master of the ship.

BARREL, in commerce, a round vessel, in the form of a small tun, for holding several sorts of merchandize.

BARREL also implies a liquid measure, and is of three kinds, wine, beer, and ale. The first contains thirty-one gallons and a half; the second thirty-six gallons; and the third thirty-two gallons.

BARREL likewise denotes a certain weight of several merchandizes, which not only differs in different commodities, but also in different places. A barrel of Essex butter weighs one hundred and six pounds; and a barrel of Suffolk butter two hundred and fifty-six pounds. The barrel of herrings ought to contain thirty-two gallons wine measure, and will hold about a thousand herrings. The barrel of salmon must contain thirty-two gallons; the barrel of eels the same. The barrel of soap must weigh two hundred and fifty-six pounds.

BARREL, in mechanics, a name given by watch-makers to the cylinder about which the spring is wrapped; and by gun-smiths to the cylindrical tube of a gun, pistol, &c. through which the ball is discharged.

BARREL, in anatomy, a pretty large cavity behind the tympanum of the ear, about four or five lines deep, and five or six wide. It is lined with a fine membrane, on which are several veins and arteries. See **EAR**.

Thundering BARRELS, in military affairs, common casks or barrels filled with powder, and rolled upon the works of an enemy, in order to set them on fire, and drive him from the place intended to be attacked.

This fire-work is sometimes nothing but a barrel of common powder, in which a fuse is inserted, and fired before the barrel is rolled towards the enemy; this fuse fires the powder in the barrel, which by its explosion creates great disorder among the troops where it takes effect.

BARRICADE, or **BARRICADO**, in naval architecture, a strong wooden rail or beam, supported by a range of small pillars or stanchions, and extending as a fence across the fore-most part of the quarter-deck. In a ship of war, the vacant intervals between the pillars are commonly filled with cork, junks of old cable, or thick mats of platted rope: and on the upper-part, about a foot above the rail, there is a double rope-netting, supported by double cranes of iron: between the two parts of the netting, are stuffed a number of hammocks, filled with the seamen's bedding, to intercept and prevent the execution of swivel-shot, (swivel is a sort of small cannon) musket-balls, &c. in the time of engagement. See **DECK**, **HAMMOCK**.

BARRICADE, in military affairs, a fence formed hastily with baskets of earth, trees, palisadoes, or the like, to preserve an army from the shot or assault of an enemy.

The most usual materials for barricades of this kind, are pales or stakes crossed with batons, and shod with iron at the feet: they are commonly erected in passages or breaches.

BARREN-WORT, *Epimedium*, in botany, a plant having a creeping root, from which arise many stalks about nine inches high, divided at the top into three, which are again divided into three smaller stalks: upon each of these stands a stiff heart-shaped leaf ending in a point; of a pale green on the upper side, but grey underneath. A little below the first division of the stalk, comes out the foot-stalk of the flowers, which is near six inches long, dividing into smaller, each of these sustaining three flowers, which are cruciform, and of a reddish colour, with yellow stripes on their borders. In the center of the flower arises the style surrounded by four filaments; the germen is oblong, which afterwards turns to a slender pod, con-

taining many oblong seeds. This plant flowers in May, and the leaves decay in autumn; but seldom ripens its seeds with us.

BARRIER, in fortification, a kind of fence made across a passage or the entrance of a retrenchment, &c.

It is composed of large stakes about four or five feet high, placed eight or ten feet distant from one another, with transoms, or over-thwart rafters to stop either horse or foot. In the middle is a moveable bar of wood, that opens or shuts at pleasure.

BARRING a Vein, in farriery, implies an operation performed on the veins of a horse's legs, and other parts of his body, in order to stop the course of the blood, and lessen the quantity of malignant humours flowing to that part. This operation, as it is founded on a false theory, so it is now never used by skillful farriers.

BARRISTER, in common law, implies a person qualified and empowered to defend the cause of clients in any of the courts of justice.

The word is formed from the Latin, *bar*, *barra*, the place where they stand to plead.

Barristers are of two sorts, distinguished by the epithets outer and inner. The outer-barristers are those who plead without the bar. The inner-barristers are those who are allowed the privilege of pleading within the bar. But at the Rolls, and some other inferior courts, all barristers are admitted within the bar.

BARROW, in some salt works, is a name given to wicker cases in the form of a sugar loaf, wherein the salt is put to drain.

BARRULET, in heraldry, signifies the fourth part of the bar, or one half of the cloiset.

BARRULY, in heraldry, is when the field is divided bar-ways, that is, across from side to side, into several parts.

BARRY, in heraldry, is when an escutcheon is divided bar-ways, that is, across from side to side, into an even number of partitions, consisting of two or more tinctures, interchangeably disposed. It is to be expressed in the blazon by the word *barry*; and the number of pieces must be specified; but if the divisions be odd, the field must be first named, and the number of bars expressed.

BARRY-BENDY is when the escutcheon is divided evenly, bar and bend-ways, by lines drawn transverse and diagonal, interchangeably varying the tinctures of which it consists.

BARRY-PILY is when a coat is divided by several lines drawn obliquely from side to side, where they form acute angles.

BARSANIANs, in ecclesiastical history, a sect of heretics in the sixth century, who followed the errors of the Cainites and Theodosians; and were so called from one Barsinius their leader.

They made their sacrifices consist in taking wheat flour

flour on the top of their fingers, and carrying it to their mouths. They never eat meat with other men; and maintained the Holy Ghost to be a creature.

BARTERING, in commerce, the exchanging one commodity for another, or sending a merchant a parcel of goods, and taking others of him in exchange.

The word is formed from the Spanish, *baratar*, to deceive, or circumvent; because, perhaps, those who deal this way, endeavour to over-reach one another.

BARTHOLOMITES, a religious order founded at Genoa, in the year 1307; but the monks leading very irregular lives, the order was suppressed by pope Innocent X. in 1650, and their effects confiscated.

BARTRAMIA, in botany, a decandrious plant, which grows naturally in both the Indies. It rises with a soft stem, about four feet high, dividing into several branches at the top, which are furnished with roundish angular leaves, soft, like those of the mallow, and a little hoary on their under side. The flowers are produced at the wings of the leaves, each having five small yellow petals, which form a short tube at their base, but spread open above the empalement; the flower is succeeded by a globular fruit, armed on every side with spines, which split into four parts, each having a single seed. This plant is perennial, and propagated by its seeds; but being a native of the hottest countries, it requires a stove in this climate.

BARUCH, the name of an apocryphal book, supposed to be the canon of the Old Testament.

It has been reckoned part of Jeremiah's prophecy, and is often cited by the ancient fathers as such. Josephus tells us, that Baruch was descended from a noble family. It is added, that he wrote the book himself, while he continued at Babylon; but at what time is uncertain.

There are three copies of this book, one in Greek, the other two in Syriac: one of the latter agrees with the Greek, but the other varies from it. In what language it was written, whether one of these copies be not the original, or which of them may be so, is difficult to determine.

BARUTH, an Indian measure containing seven-teen gantans, and ought to weigh three pounds and an half English averdupoise.

BARULES, in ecclesiastical history, a sect of heretics, who held that the Son of God had only the phantom of a body; that souls were created before the world, and that they lived all at one time.

BAS-RELIEVE. See **BASSO-RELIEVO**.

BASALTES, in natural history, a species of marble of a very fine texture, and of a deep glossy black colour.

The most remarkable quality of this marble is its figure, being never found in strata, like other marbles, but always standing up in form of regular angular columns, composed of a number of joints placed on and nicely fitted to each other, as if formed by the hand of a skilful workman. It is remarkably hard and heavy, will not strike fire with steel, and makes a fine touchstone.

The **Giants-Caufeway** in Ireland, is entirely composed of the basaltés; and is, perhaps, the most surprizing natural production of this kind in the world.

BASE, in architecture, is the lowest part or foot of a pillar on which it stands, or that part that lies upon the pedestal under the body. It is likewise used for all the several ornaments or mouldings that reach from the apophyges, or rising of the shafts of pillars, to the plinth.

BASE of a Column is that part between the shaft and pedestal, if there be any; if not, between the shaft and plinth, or zocle: the ornaments of the base are different in different orders.

The **Tuscan BASE** consists only of a single tore, besides the plinth.

The **Doric BASE** has an astragal, introduced by the moderns, more than the Tuscan.

The **Ionic BASE** has a large tore over two slender scotias, separated by two astragals.

The **Corinthian BASE** has two tores, two scotias, and two astragals.

The **Composite BASE** has two tores, two scotias, and one astragal.

The **Attic BASE** has two tores and a scotia, and is a proper base either for the Ionic or Composite columns.

BASE Rudentee, in architecture, is that which has its tores cut like cables.

BASE, in fortification, the exterior side of the polygon, or that imaginary line which is drawn from the flanked angle of a bastion to the angle opposite to it.

BASE of a Figure, in geometry, denotes the lowest part of its perimeter.

BASE of a Triangle, is properly the lowest side, or that which is parallel to the horizon, though any side occasionally is called the base.

BASE of a Solid is that side on which it stands, or the lowest part thereof.

BASE of a Conic Section is a right line in the hyperbola and parabola, formed by the common intersection of the secant plane and the base of the cone.

BASE, in perspective, the common section of a picture and the geometrical plane.

BASE, in gunnery, the least fort of ordnance, the diameter of whose bore is $1\frac{1}{2}$ of an inch, its weight 200 pound, length 4 feet, its shot a pound and

and a half in weight, and its diameter one inch and one-eighth.

BASE of the Heart, in anatomy, denotes its upper part. See **HEART**.

BASE Estate, in law, implies the estate held by a base tenure.

BASE Tenure, the holding by villenage, or other customary services.

BASE Fee is to hold in fee at the will of the lord.

BASE Court, any court not of record.

BASEMENT, in architecture, implies a base continued a considerable length, as round a house, room, &c.

BASHAW, a Turkish governor of a province, city, or other district.

BASIL, *Oryzum*, in botany, a genus of didynamious plants. One of the species called bulb-basil, has a fibrous small root, with a stalk about six inches high, spreading out into branches that are a little woody, forming an orbicular head: the leaves are like those of marjoram, of a purplish cast, standing opposite on short footstalks; the flowers are produced in whorles toward the top of the branches, of a white colour and purplish cast; they consist of a labiated petal, whose crest, or upper-lip, is erect, roundish, notched, and larger than the beard of the lower lip, and cut into five parts; the calyx is cut on the edges into four parts, the uppermost of which is hollow like a spoon, and the pistil which rises out of it is attended with four embryos, which afterward become as many seeds.

This and the common fowl are both propagated by seeds, which should be sown the beginning of April, on moderate hot-beds; and when the plants are up, they should be removed to another, observing to water and shade them till they have taken root: in May they should be taken up with a ball of earth to the roots, and transplanted either in pots or borders. These plants have a strong scent like cloves, too powerful for most persons, but to some they are very agreeable.

The leaves and seeds of basil are cephalic, cordial, and pectoral: some powder the dried leaves, and make them into snuff, which they think has a better effect than common snuff. It is also much used by some cooks in their soups and sauces.

BASIL, among joiners, the sloping edge of a chisel, or of the iron of a plane. They usually make the basil twelve degrees for soft wood, and eighteen for hard; it having been found by experience, that the more acute the basil is, the better it cuts; and the more obtuse it is, the stronger and fitter for service.

Order of St. BASIL, the most ancient of all the religious orders, and was very famous in the East during the latter part of the fourth century; though some doubt whether St. Basil was really the founder.

BASILARE Os, in anatomy, the same with os sphenoides. See **SPHENOIDES**.

BASILIC, in ancient architecture, implies a large hall, or public room, with idles, porticoes, galleries, tribunals, &c. being the term applied to those places where princes sat and administered justice in person.

The word is Greek, *basilikon*, and signifies a royal house, or palace.

The word is now used to signify such churches, temples, &c. as far surpass the other structures of the same kind in grandeur and magnificence.

BASILICA, in anatomy, the interior branch of the axillary vein, running the whole length of the arm. See **VEIN**.

BASILICON, in pharmacy, an epithet given to several compositions to be found in ancient medicinal writers. At present it is confined to two officinal ointments, distinguished by the epithets black and yellow; and formerly much used by surgeons in dressing wounds.

BASILICS, in antiquity, a body of the Roman laws, translated into Greek. In this system is comprehended the institutes, digests, code, novels, and some edicts published by Justinian and other emperors.

BASILICUS, in astronomy, a star of the first magnitude, in the constellation Leo, called also regulus, and cor leonis, or the lion's heart. See **REGULUS**.

BASILIDIANS, a sect of heretics in the second century, and so called from their leader Basilides, a disciple of Menander. He flourished in Egypt about the year 112, and there chiefly propagated his heresy.

Basilides, in the creation of things, admitted a certain successive scale, in which each link of beings created the succeeding, and were themselves created by the preceding; and consequently, that one being only owed its existence to God. He also taught that there were 365 heavens between the earth and the empyrean; and that each of these heavens had a moving and creating angel assigned to it; which angel was itself created by the next angel above him.

With regard to the Christian religion, Basilides taught, that Christ did not really suffer upon the cross; but that Simon the Cyrenean was substituted in his room; that the promiscuous copulation of men and women was lawful: that a Christian may renounce the faith to avoid martyrdom; and that the soul alone is to be saved, and the body never to rise from its state of corruption.

BASILISK, a fabulous kind of serpent, said to be produced from a cock's egg hatched by a serpent, and supposed to kill by its breath or sight only.

BASILISK, in military affairs, implies a piece of ordnance, carrying a shot of forty-eight pounds, and

and weighing about seven thousand two hundred pounds.

BASIOGLOSSUS, in anatomy, a muscle arising from the base of the os hyoides, and running along the middle of the tongue towards its apex. It is assisted by the ceratoglossus, and draws the tongue backwards.

The word is formed from the Greek, *βασίς*, the base or foundation, and *γλῶσσα*, the tongue.

BASIS, the same with base. See **BASE**.

BASKETS of Earth, in the military art, signify small baskets filled with earth, and used in sieges on the parapet of a trench. The French call them *corbeilles*. They are generally a foot and a half high, the same in diameter at the top, and eight or ten inches at bottom; so that when set together, a sort of embrasures are left at their bottoms, through which the soldiers fire, without exposing themselves.

BASKET-SALT, a very fine salt, much purer, whiter, and composed of smaller grains than the common fort.

BASKET-TENURE, a tenure of lands by the service of making the king's baskets.

BASON, in anatomy; see the article **PELVIS**.

BASON, in mechanics, a term used by glass grinders for a dish of copper, iron, &c. in which they grind convex glasses, in the same manner as concave ones are ground on spheres.

The hatters call the iron mould in which they form the matter of their hats, a *bason*; and they give the same name to the leaden one for the brims of hats; the latter has an aperture in the middle big enough for the largest block to go through.

BASON or FOUNTAIN, among gardeners, implies a reservoir for holding water either for the ornament or use of the garden.

These reservoirs are made in divers forms, some round, some oblong or oval, others square, octangular, &c. but their most common form is circular; and if the ground will permit, the larger they are the better; and when they exceed in size, they are called pieces of water, canals, fish-ponds, pools, &c.

In making these, care ought to be taken to avoid both extremes, and not to make them too big or too little, that a water-work may not take up the best part of a small piece of ground; nor to make too little a *bason* in a large spot. This must depend entirely on the judgment of the designer of the garden.

BASON of a Dock, a place where the water is prevented from running out at the tide of ebb, by double flood-gates: its use is to have ships repaired, either before they go into, or after they leave the dock.

BASON also signifies some part of a harbour, which opens from a narrow channel, into a wide and spacious reservoir for shipping.

BASONS of a Balance, the two scales or dishes

fastened, by strings or chains, to the extremities of the beam; one for holding the weights, and the other the commodity to be weighed.

BASS, in music, that part of a concert which consists of the gravest and deepest sounds, and is played on the largest pipes or strings of a common instrument, as of an organ, lute, &c.

The bass is the principal part of a musical composition, and the foundation of harmony; for which reason it is a maxim among musicians, that when the bass is good, the harmony is seldom bad; and the contrary.

Counter Bass is a second or double bass, where there are several in the same concert.

Thorough Bass, or *Bass Continuo*, is the harmony made by the bass viols, theorbos, &c. continuing to play both while the voices sing, and the other instruments perform their parts, and also filling up the intervals when any of the other parts stop. It is played by figures marked over the notes on the organ, harpichord, &c. and frequently simple and without figures, on the bass-viol and bassoon.

M. Broffard observes, that the thorough bass is a part of the modern music; and that it was invented by Ludovico Viadana, an Italian, in the year 1600.

BASSOON, a musical instrument of the wind sort, blown with a reed. It is furnished with eleven holes, and used as a bass in a concert of hautboys, flutes, &c.

BASSO-RELIEVO, or **BASS-RELIEF**, a piece of sculpture, where the figures do not protuberate, or stand out far beyond the plane on which they are formed.

BASS-VIOL, a musical instrument resembling a violin in the shape, but much larger. It is struck with a bow, like a violin, has generally the same number of strings, and eight stops, which are subdivided into semi-stops. Its sound is grave, and has a very noble effect in a concert.

BASTARD, a natural child, or one born of a woman not married.

By the laws of England, a bastard is incapable of inheriting lands, as the heir of his father; nor can any one inherit lands as heir to him, except the children of his own body; for by order of law, a bastard has no relation, and he himself is accounted the first of his family.

BASTARDY, a defect of birth, objected to one born out of wedlock, and is either general or special.

General BASTARDY is a certificate from the bishop of the diocese to the king's justices, after enquiry made whether the party is a bastard or not, upon some question of inheritance.

Special BASTARDY is a suit commenced in the king's courts against a person that calls another bastard.

BASTERNA, a sort of vehicle resembling our chariots, much used by the ancient Roman ladies.

BASTION, in fortification, is among the moderns what was formerly called a bulwark; and consists of two faces and two flanks. It is usually made at the angles of forts of a large heap of earth, sometimes lined with bricks, fods, turfs, &c. but rarely with stone.

The lines AB and CB, are the faces of the bastion B, Plate X. *fig. 4.* and the line CE, the flank of the said bastion B; likewise the line GF, GD, &c. the flank and faces of the bastion D. The line EP is called the curtain, and OB and OD, the capitals of the bastions D and B. For the different angles of the bastion, see **ANGLES**.

It is a general rule with engineers in constructing a bastion, or at least ought to be, that every part be seen and may be defended from some other part of the bastion; because angles alone are not sufficient, flanks and faces being very necessary. The faces should never be more than thirty, nor less than twenty-four Rhineland perches. The longer the flanks the better, provided they stand at right-angles, with, and under the line of defence. It is the different dispositions of the flanks that have introduced the various kinds of fortification, for on their good or bad disposition, chiefly depends the defence. The angle at the bastion should never exceed sixty degrees; otherwise it will be too small to give room for guns, and will either render the line of defence too long, or the flanks too short: it must therefore be either a right angle, or some intermediate one between that and sixty degrees.

Composed BASTION is when two sides of the interior polygon are very unequal, which also renders the gorges unequal.

Cut BASTION is that whose point is cut off, instead of which it has a re-entering angle, or an angle inwards with two points outwards; and is used either when the angle, would, without such a contrivance be too acute, or when water, or some other impediment, prevents the bastion from being carried to its full extent.

Demi BASTION has but one face and flank, and is usually before a horn-work, or crown-work. This is called an **EPAULEMENT**.

Deformed BASTION is that which wants one of the demigorges, because one side of the interior polygon is so very short.

Double BASTION is that which is raised on the plane of another bastion, leaving twelve or eighteen feet between the parapet of the lower, and foot of the higher.

Flat BASTION is a bastion built in the middle of the curtain, when it is too long to be defended by the bastions at its extremities.

Hollow BASTION is that which is only surrounded

with a rampart and parapet, having the space within void or empty.

Regular BASTION is that which has its true proportion of faces, flanks, and gorges.

Solid BASTION is that which has the void space filled up entirely, and raised to an equal height with the rampart.

BASTON, in law, implies a servant to the warden of the Fleet-prison, who attends the king's courts with a red staff, for taking into custody such persons as are committed by the court.

BASTON, or **BATOON**, in architecture, is a kind of moulding in the base of a column, called also a *tore*.

BASTON, or **BATOON**, in heraldry, is a kind of bend which has only one half of the usual breadth. It resembles a truncheon, and is the proper mark for *bastardy*.

BAT, in natural history, a kind of mungrel, or amphibious sort of animal, partaking both of the mouse and bird, and flying though without feathers.

The bat, which the Latins called *vespertilio*, seems to be a medium between the quadruped and the feathered kinds. They lay themselves up during the winter in the driest recesses of caverns; where, fixing their talons to the roof, they cover their bodies with their wings, and in that position sleep for several months.

BATABLE Ground, the lands which lay between Scotland and England, when the kingdoms were distinct, and to which both nations pretended a right.

BATCHELOR, or **BACHELOR**, a single man, who has never been married.

BATCHELOR was, formerly, a title given to those who had obtained the honour of knighthood; but had not a sufficient number of vassals to carry their banner before them in the field of battle.

BATCHELORS, in the universities, are persons who have attained to the *baccalaureate*, or taken the first degree in the liberal arts or sciences.

BAT-FOWLING, a method of catching birds in the night by lighting large candles, or torches, near the place where they are at roost; for, upon beating them up, they fly immediately to the flame, where they are easily caught in nets, or beat down with bushes fastened to the ends of poles.

BATH, *Balneum*, a sufficient quantity of water collected in some convenient receptacle for persons to wash themselves in, either for health or pleasure: and is either hot or cold.

Hot BATHS, called by the ancients *thermæ*, produce the most salutary effects in a great number of diseases; and owe their origin partly to an admixture of sulphureous particles, while the water is passing through the subterraneous canals, and partly

ly to the fumes or vapours exhaling through the pores of the earth, where sulphur is found either pure or impure, as in coals, amber, iron, nitre, &c.

Cold BATHS were held by the ancients in the greatest esteem; and the present age can boast of abundance of noble cures performed by them, and such as were long attempted in vain by the most powerful medicines.

Artificial BATHS are of various kinds, and adapted to various disorders; some are made of cephalic and nervous drugs boiled in light and pure water.

Vapour BATHS are where the vapours arising from burning spirits of wine, or from herbs boiled in wine, water, milk, &c. have immediate access to either the whole body, or some particular parts.

BATH, in antiquity, a measure of capacity used among the Jews, containing the tenth part of an omer, or seven gallons and four pints as a liquid measure; or three pecks and three pints as a dry measure.

BATHS, in architecture, superb buildings erected by the ancients for the sake of bathing.

Knights of the BATH, a military order in England, instituted according to some authors by Richard II. who confined their number to four; but others say that it was founded by Henry IV. in the year 1399, and their number limited to forty-six.

Their motto is *tres in uno*, alluding to the three theological virtues.

BATH-KOL, the daughter of a voice, a name given by the Jews to one of their oracles. It consists of a fantastical method of predicting future events by the first words they hear from any person's mouth, and which they consider as a voice from heaven to instruct them in the matter they are enquiring about.

BATH-METAL, a mixed metal, consisting of copper combined with zinc, and generally called prince's metal. See *PRINCE'S METAL*.

BATMAN, in commerce, a kind of weight used at Smyrna, containing six okes, of four hundred drams each, which amount to sixteen pounds, six ounces, and fifteen drams, English weight.

BATON, or *BASTON*. See *BASTON*.

BATRACHOMYOMACHIA, battle of the frogs and mice, the title of an elegant burlesque poem, commonly ascribed to Homer.

The word is compounded of the Greek, *Βάτραχος*, a frog, *μύς*, a mouse, and *μαχη*, a battle.

The cause of this battle is the death of *Psycharax*, a mouse, son to *Taxartes*, who being mounted on the back of *Physignathus*, a frog, on a voyage to her palace, to which he had invited him, was seized with fear, on seeing himself in the middle of a pond, so that he tumbled off and

was drowned. The mice suspecting that *Physignathus* had shaken him off with design, demanded satisfaction, and, by unanimous consent, declared war against the frogs.

BATTALIA, an army drawn up in order of battle.

BATTALION, a small body of infantry drawn up in order of battle, and ready to engage.

A battalion usually contains from five to eight hundred men; but the number is not precisely determined. They are divided into three companies, one of which is grenadiers. They are usually drawn up with six men in file, or one before another. Some regiments consist of one battalion only, while others are divided into four or five.

BATTEN, a name given by workmen to a scantling of wooden stuff, from two to four inches broad, and about an inch thick; the length is generally very considerable, but undetermined.

This term is chiefly used in speaking of doors and window-shutters which are not framed with whole deal, &c. with styles, rails and pannels, like wainfoot; but appear to the eye as if they were really such, by means of these battens, bradded on the plain board round the edges, and sometimes across them up and down, in different manners, according as the workman would imitate this or that different kinds of wainfoot.

BATTENS of the Hatches, in the marine, long narrow scantlings of board, or the hoops of barrels; they are nailed along the edges of the tarpauling, which is a piece of tarred canvas of sufficient capacity to cover the hatches at sea: the battens confine the edges of the tarpaulings close down, to prevent the water, which may rush over the decks in a storm, from penetrating into the lower apartments of the ship. See *HATCHWAY*.

BATTERING, in the military art, implies the attacking a place, work, or the like, with heavy artillery.

BATTERING-PIECES are large pieces of ordnance proper for battering a fortification. See *CANNON*.

BATTERING-RAM, a machine used by the ancients in sieges, for battering the walls and towers of a fortified place.

The use of this machine is very ancient, and the invention of it ascribed to different people. It was of two kinds, slung or unslung.

The former was composed of a large beam of oak, resembling a ship's mast, of prodigious length and thickness, having the end armed with a head of iron proportioned to the body, and resembling that of a ram, and thence it had its name. This terrible machine, which according to Vitruvius weighed 440000 pounds, was suspended, and equally balanced, like the beam of a pair of scales, with a chain, or a large cable, which supported it in the air in a strong frame of timber, which

which was pushed forwards, on the filling up of the ditch, to a certain distance from the wall, by means of rollers or wheels. The frame was secured from being set on fire by the besieged, by several coverings, with which it was then cased over.

The unsuspended ram differed from this only in the manner of working it: for, instead of being slung by a chain or cable, it moved on small wheels on another large beam.

BATTERING-RAM, in heraldry, is a bearing, or coat of arms, resembling the military engine of the same name.

BATTERY, in military affairs, all places where cannon, mortars, &c. are mounted, are called batteries, whether to fire on an enemy's troops, or to attack or destroy a fortification.

In an engagement cannon are fired without being covered, that is, without having any ground thrown up to cover or defend the persons appointed to charge and work them. For as the pieces in these cases have no fixed situation, but are perpetually changing place, as the general finds necessary, the difficulty of covering them is evident, and the haste in which these kind of actions are performed, does not permit the use of that precaution, which would render the service much less dangerous. But in the attack of a place it is otherwise, as the cannon are fixed firmly, each in its proper place, and it is absolutely necessary to their being made use of, that they should be placed behind a parapet, thick enough to resist the cannon-shot of the besieged.

The construction of a parapet is what is properly called the construction of a battery; we shall give the particulars of it, as they stand in M. de Vauban's Memoirs.

The bed of the cannon, that is, the spot on which it is placed, should, if possible, be raised some feet above the level of the field.

The parapet should be three fathoms thick, and seven feet and a half high.

These parapets are constructed of earth and fascines, which are a kind of faggots.

The situation and extent of these batteries are first marked out (so as they may be parallel to the parts of the fortification intended to be destroyed) by laying down a line, or the match-cord; this done, the ground before the battery is broke, and a small trench opened; a bed of the earth that is dug out, is first laid and well beaten down; then a layer of fascines is placed transversely upon the earth, or so that their length shall reach from side to side of the parapet, crossing it at right angles; and so alternately a bed of earth and a layer of fascines, the fascines well fastened together, and stakes driven through them, so as to make the several layers of fascines and earth as it were one body; both sides of the parapet are also faced or lined with

fascines, laid lengthways, or parallel to the parapet, and well fastened with stakes to the inside of it.

This parapet being raised two feet and an half, or three feet, the embrasures must be marked on the outside. Embrasures are well known to be the opening in parapets to receive the cannon, and the part between two embrasures is called the merlon; from the middle of one embrasure to another ought to be eighteen feet: the embrasure ought to be three feet wide on the inside, and nine feet on the outside of the parapet.

The embrasures being marked out, the rest of the parapet, called the epaulement of the battery, must be raised, leaving the space marked for the embrasures open; that part of the parapet above the embrasures must have a proper slope, or shelving, that the materials of the parapet, or of the merlons may not be beat down into the embrasures.

That part of the parapet which reaches from the ground to the bottom of the embrasures, is called the knee of the battery.

The parapet being finished, platforms must be prepared over-against the embrasures, to place the cannon upon.

These platforms are a kind of strong floors, made to prevent the cannon from sinking into the ground, and to render the working of them more easy. They are composed of joists, or pieces of wood laid lengthways, the whole length of the intended platform; and, to keep them firm in the places they are laid in, stakes must be driven into the ground close to them on each side; these joists must then be covered with very thick planks, laid parallel to the parapet; and over that part of the last which touches the inside of the parapet, a kind of thick girder, or rafter, must be placed, called a *beurton*, or *knocker*, because when the cannon is fired, the wheels of its carriage first knock or strike against it, and immediately afterwards recede from it, by the effort of the powder made against the breech of the piece, which is the cause of what is called its recoil. See the article **CANNON**.

As a check to this recoil, and to render it as little as possible, the ground, on which that part of the platform is laid which is farthest from the parapet, should be raised, as much as circumstances will permit, higher than the part nearest the parapet.

Platforms ought to be eighteen or twenty feet long, seven and an half wide near the parapet at their narrowest part, and thirteen at the widest.

When the platforms are finished, the cannon must be brought to the batteries, and placed with their carriages on the several platforms allotted them.

It is usual to make little cells or cavities near the batteries, and at a convenient distance from each

Fig. 1. Plan of a Battery of Cannon.

Fig. 2.

Profile of a Battery of Cannon

Platforms with Mortars

Profile of a Bomb Battery.

Fig. 1. View of the building from the front.

each other, in which to keep the gun-powder. These cells are covered with clay, or something of the like kind, to preserve them from being fired, and are called little magazines of the battery. A place is prepared at a greater distance, where a larger quantity of powder is kept, which serves as a magazine to the smaller places just mentioned. The powder is thus divided to prevent accidents by fire, and these magazines are guarded by soldiers sword in hand.

All that remains concerning batteries of cannon, after what we have said on the subject, will be seen by the fig. 1. in Plate XIX.

Fig. 1. represents the plan of a battery, with its platforms, and the cannon placed thereon, facing the embrasures.

Fig. 2. shows the profile of a battery, with a piece of cannon, in its embrasure, ready to be fired.

After having treated of the batteries of cannon, it is proper to give some account of the batteries of mortars; but these differ little from the former. They are constructed in the same manner, except that they have no embrasures; they have also platforms made in the same manner with those of cannon. Plate XIX. fig. 3. exhibits the plan of one of those batteries, with a profile, representing a mortar at the moment of giving fire.

When the enemy is near enough to see or command the batteries in flank, his view must be cut off, by continuing the parapet of the battery in another angle, as represented in the figure of the battery of cannon, referred to above.

The bullets and bombs are laid down in readiness, beside the merlons, between the embrasures.

Besides these, there are batteries of various kinds, as sunk, direct, sweeping, reverse, cross, and rebounding batteries.

Sunk BATTERIES have their platforms sunk below the level of the field, so as that the ground serves for the parapet, in which embrasures may be made.

Direct BATTERIES are those which batter the sides of the work, before which they are placed almost at right angles.

Sweeping BATTERIES, or batteries *d'enfilade*, are those which scour or sweep the sides of some work in a straight line.

The Reverse (*revers*) are those which batter from behind, that is, play on the backs of those posted on the work to defend it.

Cross BATTERIES are those which play athwart each other, and whose fires, if continued after their meeting, would almost cross at right angles.

Rebounding BATTERIES, (or batteries *d'echappe*) are those whose stroke make no more than an angle of twenty degrees, with the faces or sides of what they are directed against. These are also sometimes called *glancing batteries* (*de bricole*) because

the bullet, only glancing, as it were, on the place it is directed against, is thrown off to the parts adjacent, almost like the bricole, or transverse stroke at billiards, which falls on the cushion in an oblique direction.

BATTERY, in law, the striking, beating, or offering any violence to another person, for which damages may be recovered; but if the plaintiff made the first assault, the defendant shall be acquitted, and the plaintiff amerced to the king for his false suit.

Battery is frequently confounded with assault, though in law they are different offences; and the defendant may be found guilty of assault, though acquitted of the battery: there may therefore be an assault without a battery; but battery always implies an assault. See ASSAULT.

BATTEURS *d'Estrade*, are scouts sent out on horseback before the front, and on the wings of an army, some miles distance to make discoveries.

BATTLE, a general engagement between two armies, in a country sufficiently open for them to encounter in front, and for the greater part at least of the line to engage. Other great actions, though of a longer duration, and perhaps attended with greater slaughter, are only called fights.

Naval BATTLE. See the articles SEA-FIGHT, ENGAGEMENT, LINE, DIVISION.

BATTLE is also used figuratively for a representation of a battle in sculpture, painting, &c.

BATTLE-ROYAL, among sportsmen, implies a fight between three, five, or seven cocks, all engaged together, so that the cock which stands longest wins the battle.

BATTLE-AX, a kind of halbert formerly used by the infantry, and first introduced into England by the Danes.

BATTLEMENTS, in architecture, are indentures or notches in the top of a wall, or other building, in the form of embrasures.

BATTOLOGY, in grammar, implies a superfluous repetition of some words or sentences.

BATTON, or BATTOON. See BASTON.

BATTERY, in commerce, a name given by the Hanse-towns to their warehouses in foreign countries.

BAVINS, in the military art, are faggots of brush-wood, with the brush at length.

BAUHINIA, in botany, a genus of decandrious plants, the flower of which consists of five lanceolated petals, with attenuated and reflexed tops; it hath ten filaments topped with ovated anthers; the style is filiform, and placed on an oblong germen, which turns to a long cylindrical legumen, containing many roundish compressed seeds.

BAUM, *Melisa*, in botany, a genus of didynamous plants. The common sort cultivated in gardens,

gardens, hath a long, round, fibrous, perennial root; from which arises a square stalk, which is annual, and branched. The leaves, which are set by pairs at each joint, are oblong, pointed, of a dark green, dented at their edges, and somewhat hairy, in the bosoms of which come forth the flowers, which consist of a single labiated petal, whose upper-lip is roundish, upright, and indented at the extremity in two parts; but the under-lip is cut into three parts; the pistillum is attended with four embryos, that turn to as many seeds, joined together, of a roundish shape, sitting in the calyx; the flowers are white, and appear in July: the whole plant has an agreeable scent, somewhat like lemons. It is propagated by planting the roots in autumn, which may be divided into small pieces, and planted in beds of common earth, at about a foot asunder.

Baum is said to be cordial, cephalic, and to fortify the stomach; it is taken in the manner of tea, and is by some greatly esteemed for that purpose, and acidulated with lemon juice, as a diluter in acute disorders.

Molucca BAUM. See MOLUCCELLA.

Turkey BAUM. See DRACOCEPHALUM.

BAY, a gulph or inlet of the sea-coast, comprehended between two capes or points of land, where vessels frequently ride at anchor sheltered from the wind.

BAY, among farmers, that part of a barn where the corn is laid up, or the mow made. Thus if a barn consist of a floor and two heads, they call it a barn of two bays.

BAY is also one of the colours of the coat of horses, and has, perhaps, its name from resembling the colour of dried bay-leaves.

There are various degrees of this colour from the lightest bay to the dark, that approaches the nearest to the brown, but always more gay and shining. The bright bay is an exceeding beautiful colour, because a bright bay horse has often a reddish dash with a gilded aspect, his mane and tail black, with a black or dark list down his back. The middle colours of bay also have often the black list with black mane and tail; and the dark bays have almost always their knees and pasterns black, and we meet with several sorts of bays that have their whole limbs black from their knees and hocks downwards. The bays that have no lists down their backs, are, for the most part, black over their reins, which goes off by an imperceptible gradation from dark to light, towards the belly and flanks: some of these incline to a brown, and are more or less dappled.

The bay is one of the best colours, and horses of all the different kinds of bays are commonly good, unless when accidents happen to spoil them when they are colts. *Gibson on Horses.*

BAY, among huntsmen, is a term applied to a

deer, which after having been hard run, turns about, and defends himself with his horns against the dogs; in which case he is said to stand at bay.

BAY-SALT. See SALT.

BAY-TREE, *Laurus*, in botany. This plant in hot countries grows to a considerable height, has a smooth trunk without knobs, and long branches. The leaves are long, sharp, hard, nervous, and smooth; but have little juice, though they have a fine smell, and an acrid, bitter, astringent taste. The flowers consist of a single petal, which is shaped like a funnel, and divided into four or five segments, and are male and female: the embryo of the female flowers becomes a berry, inclosing a single seed, within a horny shell, which is covered with a skin. Bay-trees are propagated either from the seeds, or by laying down the branches.

This tree, among the ancients, was accounted a panacea; and the leaves, berries, and bark of the roots, were of use. The leaves are heating, resolvent, strengthen the stomach, help digestion, and disperse wind: for these purposes the infusion may be drank as tea, or the powder may be given to the quantity of a dram. The berries are more heating than the leaves, and two scruples in infusion is a dose; but their principal uses in the present medical practice is in clysters, and the leaves as a fomentation.

BAY, *Sweet-flowering*, in botany, a species of the tulip tree. See MAGNOLIA.

BAYONET, in the military art, implies a short broad dagger, with a hollow handle of iron, of a circular form, fitted to the muzzle of the piece where it is fastened; so that the soldier fires with the bayonet on the muzzle of his piece, and is always ready to act against the horse.

BAYS, in commerce, a sort of open woollen stuff, having a long nap, sometimes frized, and sometimes not. It is without any wale, and wrought in a loom with two treddles like flannel.

Bays are chiefly manufactured at Colchester and Bocking, in Essex. The exportation of this stuff was formerly more considerable than at present, the French having now learned the manufacture. The English bays are, however, still sent in great quantities to Spain and Portugal, and even to Italy. Their chief use is for cloathing the monks and nuns, and for lining the soldiers cloaths. The looking-glass makers also use bays, behind their glasses to preserve the tin foil.

The breadth of bays is commonly from a yard and a half to two yards, and the length from forty-two to forty-eight.

BAZAR, or BAZAARD, among the eastern nations, a market, or place designed for trade.

BAZAT, in commerce, a long, fine cotton, brought from Jerusalem, and is thence often called Jerusalem cotton.

BDELLIUM, in the materia medica, a gummy resinous juice, flowing from an oriental tree of which we have no description. It is brought from Arabia and the East Indies in pieces of different magnitudes, of a dark reddish brown colour externally, not unlike myrrh; but internally clear, and something resembling glue. It is of an agreeable smell, and a bitterish slightly pungent taste.

This gummy resin is recommended as a corroborant and attenuant in disorders of the breast, for promoting urine and the menses, and externally for resolving or maturing hard tumours; but is at present little used.

BEACON, a signal erected on some hill or eminence, for giving notice of the invasion of an enemy.

It consists of pitch-barrels placed upon high poles, and when the enemy appears, the barrels are set on fire; so that the flame in the night-time, and the smoke in the day, spreads the alarm thro' the whole country.

BEACON also signifies a mark erected as a warning to seamen against rocks, shelves, or sands.

BEACONAGE, the tax paid for maintaining a beacon.

BEAD, in architecture, a round moulding, commonly made upon the edge of a piece of stuff, in the Corinthian and Composite orders, cut or carved in short embossments, like beads in necklaces.

Sometimes a plain bead is set on the edge of each fascia of an architrave, and sometimes even an astragal is cut in this manner. A bead is often placed on the lining board of a door-case, and on the upper edges of skirting-boards.

BEAD-PROOF, among distillers, a fallacious method of determining the strength of spirits.

It consists in shaking a small quantity of the spirits in a phial, when if the crown of bubbles stand for some time on the surface, the goods are esteemed proof, that is, equal parts of rectified spirits and phlegm.

BEAD-TREE. See **MELIA**.

BEAGLE, the name of a particular kind of hunting-dogs, of which there are several forts.

BEAK, the bill or nib of a bird, from the form and structure of which Linnaeus divides the whole class into six orders. See **BIRDS**.

BEAK, in architecture, the small fillet left on the head of a larmier, which forms a canal, and makes a kind of pendant.

Chin **BEAK**, a moulding the same with the quarter-round, except its situation, which is inverted.

BEAK-HEAD, in naval architecture, the name given to a ship's head whose fore-castle is square; a circumstance common to all vessels of war that have two or more decks of guns. In smaller ships, the fore-castle is generally shaped like a parabola whose vertex lies immediately above the stem.

The strong projecting pointed beaks used by the ancients in time of battle, are entirely disused since the invention of gun-powder.

BEAKED, in heraldry, a term used to express the beak or bill of a bird. When the beak or bill of a bird are of a different colour from that of the body, they say beaked and membered of such a tincture.

BEAM, in architecture, is the largest piece of timber in any building lying across it, and into which the feet of the principal rafters are framed. No building has less than two of these beams, that is, one at each head; and into these beams, the girders of the garret-floor are framed, as well as the teazle-tenons of the posts, if the building be of timber.

The force and strength of beams has been considered by the best authors, both in England and France, who have given precise computations for the resistance of each, according to its length, and the dimensions of the sides; and, accordingly, the proportion of beams near London has been fixed by statute as follows: A beam of 17 feet long must have the side of one of its square sides ten inches, and the other six; one of sixteen feet long must have one eight, and the other six; one of fifteen feet, seven, and the other five inches.

Mr. Parent, a French mathematician, has endeavoured to prove, that if a beam in form of a parallelepipedon be fixed horizontally against a wall, its resistance against breaking at the place of its insertion will be as the area of the section at the wall, and the depth of the beam directly, and the length inversely.

Let R and r represent the resistances of two beams, fixed as above, whose lengths, breadths, and depths, are L , B , D , and l , b , d , respectively: then

$$\text{will } R : r :: \frac{B \times D^2}{L} : \frac{b \times d^2}{l}.$$

If P and p represent the respective weights that being appended at the extremities of their lengths, are sufficient to break those beams, we shall

$$\text{have } \frac{B \times D^2}{L} = P, \text{ and } \frac{b \times d^2}{l} = p; \text{ therefore } P \times p = \frac{B \times D^2 \times l + L \times b \times d^2}{L + l}.$$

If the beam be fixed at both ends, then $B=b$, and $D=d$, whence $P+p = \frac{B \times D^2 \times L + l}{L \times l}$, which

shews that the forces requisite to break a beam in different points of its length, are as the rectangle of the segments of the length; for $B \times D^2 \times L \times l$ being constantly the same, it follows, that $P+p$

is as $\frac{1}{L \times l}$; and, therefore, when $L=l$, $P+p$ will

be the least possible; consequently a beam supported at both ends will require a less weight to break it in the middle, than at any other point of its length.

Hence if the bases of two beams be equal, tho' both their heights and breadths be unequal, their resistance will be as their heights alone; and, by consequence, one and the same beam laid on the smallest side of its base, will resist more than when laid flat, in proportion as the first situation gives it a greater height than the second: and thus an elliptic base will resist more, when laid on its greatest axis, than when on its smallest.

Since in beams equally long, it is the bases that determine the proportion of their weights or solidities, and since their bases being equal, their height may be different; two beams of the same weight may have resistances differing to infinity: thus, if in the one the height of the base be conceived infinitely great, and the breadth infinitely small, while in the other the dimensions of the base are infinite; the resistance of the first will be infinitely greater than that of the second, tho' their solidity and weight be the same. If therefore all required in architecture were to have beams capable of supporting vast loads, and at the same time be of the least weight possible, it is evident they must be cut as thin as laths, and laid edgewise.

If the bases of two beams be supposed unequal, but the sum of the sides of the two bases equal, E. g. if they be either 12 and 12, or 11 and 13, or 10 and 14, &c. so that they always make 24; and farther, if they be supposed to be laid edgewise; pursuing the series, it will appear that, in the beam of 12 and 12, the resistance will be 1728, and the solidity or weight 144; and that in the last, or 1 and 23, the resistance will be 529, and the weight 23: the first therefore, which is square, will have less than half the strength of the last, with regard to its weight.

Hence Mr. Parent remarks, that the common practice of cutting the beams out of trees, as square as possible, is ill husbandry: he hence takes occasion to determine geometrically what dimensions the base of a beam to be cut out of any tree proposed shall have, in order to its being of the greatest possible strength; or, which is the same thing, a circular base being given, he determines the rectangle of the greatest resistance that can be inscribed; and finds that the sides must be nearly as 7 to 5. To investigate this proportion of the sides, put r for the radius of the given circular base, $2x$ for the required depth; then will

$2\sqrt{r^2 - x^2}$ express the required breadth, by the nature of the circle; and consequently $8x^2 \times \sqrt{r^2 - x^2}$ the resistance, which must be a maximum; and therefore its fluxion = 0: hence we get $x = r \times \sqrt{\frac{2}{3}}$

and the proportion of the side as $\sqrt{2}$ to 1, or 1.4 to 1 nearly, that is, as 7 to 5.

Hitherto the lengths of the beams have been supposed equal; if they are unequal, the bases will resist so much the less as the beams are longer.

To this it may be added, that a beam sustained at each end, breaking by a weight suspended from its middle, does not only break at the middle, but also at each extreme; or, if it does not actually break there, at least immediately before the moment of the fracture, which is that of the equilibrium between the resistance and the weight, its fibres are as much stretched at the extremes, as in the middle. So that, of the weight sustained by the middle, there is but one third part which acts at the middle, to make the fracture; the other two only acting to induce a fracture in the two extremes.

A beam may either be supposed loaden only with its own weight, or with other foreign weights, applied at any distance, or else only with those foreign weights. Since, according to M. Parent, the weight of a beam is not ordinarily above $\frac{1}{10}$ part of the load given it to sustain; it is evident that, in considering several weights, they must be all reduced by the common rules to one common center of gravity.

Mr. Parent has calculated tables of the weights that will be sustained by the middle in beams of various bases and lengths, fitted at each end into walls, on a supposition that a piece of oak of an inch square and a foot long, retained horizontally by the extremes, will sustain 315 lb. in its middle, before it breaks, which it is found, by experience, it will. See *Mém. Acad. R. Scienc. an. 1708*.

BEAMS, in naval architecture, thick strong pieces of timber, stretching across the ship from side to side, to support the decks and retain the sides at their proper distance.

On the BEAM, in navigation, any distant object is so called when it bears on a line with the ship's beams; thus, if a ship lies north and south, any object on the beam must bear east or west; and hence,

Before the BEAM is an arch of the horizon included between a line, crossing the ship at right angles, and the object seen in that situation: thus, if a ship steers north, and discovers another two points before the starboard-beam, she bears E. N. E. and so abaft the beam.

BEAM, in heraldry, the principal horn of a hart or buck.

BEAM, among hunters, the main stem of a deer's head, or that part which bears the antlers, royals, and tops.

BEAM, in mechanics, the lath, or iron, of a pair of scales.

BEAM is also the name of a fiery meteor, in the form of a pillar.

BEAM, or ROLLER, among weavers is a long and thick woollen cylinder, placed lengthwise on the back part of the loom of those who work with the shuttle. The threads of the warp are rolled upon the beam, and unrolls as the work proceeds.

BEAM-COMPASS, an instrument consisting of a square wooden or cross-beam, having sliding sockets that carry steel or pencil points; and used in describing large circles, where the common compasses are useless.

BEAM of an *Anchor*, the shank or longest part of an anchor. See *ANCHOR*.

BEAM of a *Plough*, a name given by our farmers to the largest piece of timber in a plough, and to which all the parts of the plough-tail are fixed.

This beam is generally made of ash, is straight, and eight feet long in the common plough; but in the four-coultered plough, it is ten feet long, and arched at the upper part. The head of this beam lies on the pillow of the plough, and is raised higher, or sunk lower, as that pillow is elevated or depressed by sliding along the crow-staves. Near the middle it has an iron collar, which receives the tow chain from the box; and the bridle-chain from the stake or gallows of the plough is fixed to it a little below the collar: some inches below this there is a hole, in which the coulter is fastened, and below that are two other small holes through which the heads of the retches, or irons that support both the sheat and the share, pass. Farther backward still is a large perforation, through which the body of the sheat passes; and behind that, very near the extremity, is another hole, through which the piece called the hinder sheat passes. See *PLOUGH*.

BEAN, *faba*, in botany, the name of a genus of plants whose flower is of the papilionaceous kind: the root is partly straight and partly creeping, with a quadrangular stalk that is light, and has several ribs: the conjugation of the leaves are not exact; for there has been sometimes three, four, five, or more of an oblong roundish shape, that are flat, and of a bluish green, venous, and smooth: the flowers proceed from the hollows where the ribs join to the stalk; and though several of them are together, they have but one pedicle: these are succeeded by a pod, so well known that it needs no description. There are several varieties of garden-beans, the most common of which are: 1. The Magazan, or Portugal-bean: 2. The Spanish: 3. The Sandwich: 4. The Toker: and 5. The Windfor-bean. The first sort should be planted in October or November, under walls, hedges, &c. and carefully earthed up as they grow: these, if not destroyed by severe weather, will be fit for table the beginning of May: though its bean is smaller than the other sorts, yet its hardiness, and coming in so

early before the others, makes it deserve notice. The Spanish and Windfor beans, being more tender, should not be planted until after Christmas. The Sandwich is a plentiful bearer, and, being hardier than the Windfor, may be planted a month sooner. The Toker-bean comes about the same time as the Sandwich, and as it is a great bearer as well as that, it is now much planted. To have a succession of Windfor-beans, there should be several plantations made at the distance of about three weeks from the first sowing to the middle of May. The Magazan-beans may also be raised in beds, sowing them thick, and covered with hoops and mats in bad weather in the winter, and in spring planted out; though they will be later than those which have stood the winter abroad, yet, if they are cut off by the severity of the weather, the transplanted ones make a good supply in their stead. All the large sorts of beans should not be planted less than three feet asunder, row from row, and about seven or eight inches in the rows. The horse-bean delights in a strong moist soil, and an open exposure; the season for sowing them is from the latter end of February to the beginning of April, according to the nature of the soil. With regard to the nature and faculty of beans, the common opinion is, that they are windy and hard of digestion, and some doubt whether they nourish much or not. The meal of dried beans is reckoned among one of the four resolvent meals; and it is used by some as a cataplasm, boiled in milk, to resolve and suppurate tumours; the water distilled from the flowers is looked upon as a cosmetic, and is still in use to take away spots from the face.

BEAN *French*. See *PHASEOLUS*.

BEAN *Trefoil*. See *CYTISUS*.

BEAN-TREE, *Kidney*. See *GLYCINE*.

BEAR, *Ursa*, in zoology, a genus of quadrupeds, of the order of the *feræ*, or beasts of prey; distinguished by having only four teats, two on the breast, and two on the belly.

It is a large, but unightly animal, and of different sizes in different countries.

BEAR *Greater and Lesser*, in astronomy; see the articles *URSA Major* and *Minor*.

BEARBIND. See *CONVOLVULUS*.

BEAR'S-BRECH. See *ACANTHUS*.

BEAR'S-EAR. See *AURICULA*.

BEAR'S-FOOT. See *HELLEBORUS*.

BEARD of a *Comet*, in astronomy, the rays which the comet emits towards that part of the heavens whither it seems to direct its motion; and it is this that distinguishes the beard from the tail, which implies those rays that are emitted in the tract through which it has passed.

BEARD of a *Horse*, that part underneath the lower jaw, between the chin and the place where the curb rests.

BEARDED

BEARDED Husk, among florists, implies a husk that appears hairy on the edges; as that of a rose, &c.

BEARING of Wool. See **WOOL**.

BEARER, in architecture, a post, pier, or wall, erected between the two ends of a piece of timber, to shorten its bearing, or to prevent its whole weight resting on the two ends only.

BEARER of a Bill of Exchange, the person in whose hands the bill is, in favour of whom the last order was made. See **BILL of Exchange**.

BEARING, in navigation, an arch of the horizon, comprehended between the nearest meridian and any distant object, either discovered by the eye, or found by the finical proportion; as, at four P. M. we discovered Cape Malacha, bearing W. 64°. S. or, having the difference of latitude and longitude given, we find the bearing and distance by analogy.

BEARING of a piece of Timber, among carpenters, signifies the space either between its two fixed extremes, when it has no other support, which they call bearing at length, or between one extreme and a post, brick-wall, &c. trimmed up between the ends to shorten its bearing.

BEARING Claw, among cock-fighters, are the foremost toes of a cock. If these are hurt or gravelled, he cannot fight.

BEAR-UP, or **BEAR-AWAY**, in navigation, a ship is said to do so when, having failed some time with a side-wind, she alters her course and sails more before it: this is probably called bearing-up, because the helm is borne up to the wind-side of the ship; for, otherwise, it is not only absurd, but an absolute contradiction to say a ship bears up when she goes before the wind, since the direction of the wind, as well as the current of the tide in a river, is understood to determine the situation of places within its limits; for we always say, up to the windward, and down to the leeward: and yet, absurd, and contradictory as it is to common sense, this phrase is adopted in the instruction of our navy, in the room of bear-away or bear-down.

BEAST, a general appellation for all four-footed animals, whether proper for food, labour, or sport.

BEASTS of Burden, all four-footed animals used in carrying burdens. These are chiefly elephants, camels, dromedaries, horses, mules, asses, and the sheep of Mexico and Peru.

BEASTS of Chace, are the buck, the doe, the fox, the roe, and the martin.

BEASTS and FOWLS of the Warren, are the hare, the coney, the pheasant, and the partridge.

BEASTS of the Forest, are the hart, the hind, the boar, and the wolf.

BEATIFICATION, an act whereby the pope declares a person beatified or blessed. It is the

first step towards canonization. See **CANONIZATION**.

BEATING, or **PULSATION**, in medicine, the reciprocal motion, or palpitation of the heart. See **PULSE**.

BEATING Gold and Silver. See **GOLD-BEATING**, &c.

BEATING, in navigation, the act of making a progress against the wind, by tacking. See the article **TACKING**. Beating, however, is generally understood to be turning to wind ward in a storm or fresh wind.

BEATS of a Watch or Clock, are the strokes made by the fangs or pallets of the spindle of the balance, or of the pads in a royal pendulum. See **CLOCK** and **WATCH**.

BEAVER, *Fiber*, in natural history, a creature about four feet in length, and twelve or fifteen inches broad. His skin, in the northern regions, is generally black, but it brightens into a reddish tincture in the temperate climates. He is covered with two sorts of hair, one long, and the other a soft down; the latter, which is an inch in length, is extremely fine and compact, and accommodates the animal with a necessary warmth. The long hair preserves the down from dirt and humidity.

The beaver, whether male or female, has four bags under his intestines, impregnated with a resinous and liquid substance, which, when it is ejected, settles into a thick consistence. See **CASTOR**.

His teeth are strong, and deeply riveted into his jaws, with a long and crooked root; with these he cuts as well the wood with which he builds, as that which furnishes him with food. His fore-feet resemble those of such animals as hold what they eat with their paws, as apes, for instance, and rats, and squirrels; with these feet he digs, softens, and works the clay, which is extremely serviceable to him. His hind feet are accommodated with membranes, or large skins, extending between his toes, like those of ducks and all other water-fowl; this makes it evident that the Author of nature intended the creature should be amphibious. His tail is long, a little flat, entirely covered with scales, supplied with muscles, and perpetually lubricated with oil or fat. This animal, who is an architect from his nativity, uses his tail instead of a hod, for the conveyance of his clay or mortar, and a trowel to spread and form it into an incrustation; the scales prevent these materials from penetrating the tail with their coldness and humidity; but would be injured by the air and water, were it not for the prevention of an oil, which he distributes all over them with his snout; the bags we have already mentioned are undoubtedly the magazines of this fluid.

Merchants distinguish three sorts of beavers, though

though they are all the skins of the same animal: the new beaver, the dry beaver, and the coat beaver.

The new beaver, which is also called white beaver, or Muscovy beaver, because it is commonly kept to be sent into Muscovy, is that which the savages catch in their winter hunting. It is the best and the most proper for making fine furs, because it has lost none of its hair by shedding.

The dry beaver, which is sometimes called lean beaver, comes from the summer-hunting, which is the time when these animals lose part of their hair.

Though this sort of beaver be much inferior to the former, yet it may also be employed in furs; but it is chiefly used in the manufacture of hats. The French call it summer castor, or beaver.

The coat beaver is that which has contracted a certain gross and oily humour from the sweat which exhales from the bodies of the savages who wear it for some time. Though this sort be better than the dry beaver, yet it is used only in the making of hats.

Besides hats and furs, in which the beaver's hair is commonly used, they attempted in France, in the year 1699, to make other manufactures with it; and accordingly they made cloths, flannels, stockings, &c. partly of beaver's hair, and partly of Segovia wool. This manufactory, which was set up at Paris, in St. Anthony's suburb, succeeded at first pretty well; and, according to the genius of the French, the novelty of the thing brought into some repute the stuffs, stockings, gloves, and cloth, made of beaver's hair: but they went out of fashion of a sudden, because it was found, by experience, that they were of a very bad wear, and, besides, that the colours faded very much: when they had been wet, they became dry and hard, like felt, which occasioned the miscarriage of the manufactory for that time.

When the hair has been cut off from the beaver's skin, to be used in the manufactory of hats, those skins are still employed by several workmen; namely, by the trunk-makers, to cover trunks and boxes; by the shoe-makers, to put into slippers; and by turners, to make sieves for sifting grain and seeds.

BEAUTY, a general term for whatever excites in us pleasing sensations, or an idea of approbation.

We may therefore distinguish the notion annexed to beauty into ideas and sensations; the former of which possess the mind, the latter affect the heart. Thus an object may please the understanding, without interesting the senses; and, on the other hand, agreeable sensations may be excited by objects whose ideas have no claim to our approbation.

In these distinctions the difficulty, or rather im-

possibility, of fixing a general characteristic of beauty consists; because the ideas and sensations of different persons vary, according to their different turns of mind and habitudes of body: and consequently the relations of objects to those ideas and sensations vary in the same manner. Hence arise the various opinions of beauty in women, painting, statuary, &c.

BEAUTY, in architecture, painting, and other arts, is the harmony and justness of the whole composition taken together.

BECAH, or **BEKAH**, in antiquity, a Jewish coin; worth nearly fourteen-pence of our money.

BECALMING, in navigation. When the wind is interrupted in its passage to a vessel by any contiguous body, as land, a high sea behind, or another ship, it is called becalming her, as the sails at that time remain in a state of rest, and are deprived of their growing power.

BECA-BUNGA, in botany, the same with *anagallis*. See **ANAGALLIS**.

BECHICS, among physicians, medicines adapted to the cure of coughs.

The word is formed from the Greek, *βηξ*, *βηξε*, a cough.

BED of the Carriage of a Cannon, the thick plank that lies under the piece, and forming, as it were, the body of the carriage. See **CANNON**.

BED, in masonry, a course or range of stones.

BED, in gardening, a square or oblong piece of ground, raised a little above the level of the adjoining ground, and in which seeds are sown, or plants set.

Hot BED. See **HOT-BED**.

BEDS of Minerals, certain strata or layers of matter disposed over each other.

Lords of the BED-CHAMBER, in the British customs, ten lords, who attend in their turns each week; during which time they lie in the king's bed-chamber, and wait upon him when he dines in private.

BED-MOULDING is a term used by workmen, for those members in a cornice which are placed below the coronet, or crown, and usually consists of an ogee, list, large boutine, and under the coronet another list.

BEE, in natural history, a small insect, famous for its industry.

With respect to form, the bee is divided by two ligaments, into three parts or portions, the head, the breast, and the belly. The head is armed with two jaws and a trunk, the former of which play like two saws, opening and shutting to the right and left. The trunk is long and taper, and extremely pliant and flexible, being destined by nature for the insect to probe to the bottom of the flowers through all the impediments of their chives and foliage, and drain them of their treasured sweets: but were this trunk to be always extended, it would

would prove inconvenient, and be liable to be injured by a thousand accidents: it is therefore of such a structure, that, after the performance of its necessary functions, it may be contracted, or rather folded up; and besides this, it is fortified against all injuries by four strong scales, two of which closely sheathe it, and the two others, whose cavities and dimensions are larger, encompass the whole. From the middle part or breast of the bee grow the legs, which are six in number: and at the extremity of the paws are two little hooks, discernible by the microscope, which appear like sickles, with their points opposite to each other. The wings are four, two greater and two smaller, which not only serve to transport them through the air, but, by the noise they make, to give notice of their departure and arrival, and to animate them mutually to their several labours. The hairs with which the whole body is covered, are of singular use in retaining the small dust that falls from the chives of the flowers, of which the wax is formed, as will be observed hereafter. The belly of the bee consists of six rings, which slide over one another, and may therefore be lengthened or contracted at pleasure; and the inside of this part of the body contains the intestines, the bag of honey, the bag of poison, and the sting. The office of the intestines is the same as in other animals. The bag of honey is transparent as crystal, containing the sweet juices extracted from flowers, which the bee discharges into the cells of the magazine for the support of the community in winter. The bag of poison hangs at the root of the sting, through the cavity of which, as through a pipe, the bee ejects some drops of this venomous liquor into the wound, and so renders the pain more excessive. The mechanism of the sting is admirable, being composed of two darts, inclosed within a sheath that tapers into a fine point, near which is an opening to let out the poison. The two darts are ejected through another aperture, which, being armed with several sharp beards like those of fish-hooks, are not easily drawn back again by the bee; and indeed she never disengages them if the wounded party happens to start and put her into confusion; but if one can have patience to continue calm and unmoved, she clinches those lateral points round the shaft of the dart, by which means she recovers her weapon, and gives less pain to the person stung. The liquor which at the same time she infuses into the wound, causes a fermentation, attended with a swelling, which continues several days; but that may be prevented by immediately pulling out the sting, and enlarging the puncture, to let the venomous matter have room to escape.

Let us now consider the generation, polity, and labours of these insects, the true knowledge of which is very much owing to the modern invention of glass-hives, through which all the secrets of

the community are laid open to a curious observer. Any person who carefully examines a hive at different seasons of the year, will distinguish three sorts of bees; of which the far greater number are the common working bees, who do all the business of the hive, and seem to be neither male nor female. The working bee is represented at C (Plate XX. *fig. 1.*) The second sort, called drones, are the males, are somewhat larger, (as A, *fig. 2.*) have no sting, nor even stir from the hive, but live upon the honey prepared by the others. The third sort is a much larger and longer-bodied bee, of which there is often but one in a hive, at least, but one in every swarm or colony of young bees, who are from time to time detached from the hive in search of another habitation. This large bee is what the ancients called the king, from the respect they always saw paid to it by the other bees; but, being the female, the moderns more properly give it the title of queen, or mother of the swarm. See Plate XX. *fig. 2. B.*

While the hive is sufficient to contain the bees without inconvenience, the society live peaceably together; but when their numbers are multiplied, so that their habitation is too small, the young brood quit the place of their nativity, and fly in quest of a new settlement. The swarm that goes out consists of the common bees, under the conduct of one female or queen; or, if two queens come out of the same hive, then the body of common bees divides into two parts, each following one female: both parties, however, when they alight out of the air, usually settle near each other on a branch of a tree; and then those bees which form the smallest swarm go off, one by one, to the other cluster, deserting the queen they followed, who is at length murdered by her subjects. The swarm being thus united, and hanging down from the tree, the countryman, who is always vigilant on those occasions, provides for their accommodation a hive rubbed with balm, thyme, and other odoriferous herbs, into which he gently brushes them from the branch, and carries them to a stand prepared for that purpose. All this the bees bear very patiently, and, after they are a little composed, begin to think of forming themselves convenient apartments in their new habitation.

When they begin this work, it is observed they divide themselves into four parties, one of which is destined to the fields to provide materials for the structure; the second works upon those materials, and forms them into a rough sketch of the dimensions and partitions of the cells; the third examines and adjusts the angles, removes the superfluous wax, polishes the work, and gives it its necessary perfection; and the fourth is employed in bringing provisions to the labourers.

M. Maraldi takes notice that the bees employed in polishing the combs, work longer than those that

BEE

that build them, because polishing is not so laborious. They begin their work at the top of the hive, continuing downwards to the bottom, and from one side to another; and to make it the more solid they use a sort of tempered wax, resembling glue. The form of the cells of the honey-comb is hexagonal, which figure, besides what is common with a square and equilateral triangle, has the advantage of including a greater space within the same surface. See the article COMB.

The expedition of the bees in their labour is almost incredible; for, notwithstanding the elegance and just proportions of the work, they are so indefatigable, that they will, in one day, finish a honey-comb, a foot long, and six inches broad, capable of receiving three thousand bees.

It is not easy to know, particularly, the manner in which they employ themselves at this work, on account of the number of bees then in motion, by which means the eye can hardly distinguish any thing but confusion. We have however been able to observe the following particulars: Some bees, bearing in each of their talons a little piece of wax, are seen running to the places where their companions are at work upon the combs; at their arrival they fasten the wax to the work by means of the same talons, which they apply sometimes to the right, and sometimes to the left. Each bee is employed but a short time on this work, when another takes its place.

While a part of the bees are at work in constructing the cells, others are employed in perfecting those that are newly modelled, finishing the angles, sides, and bases, in so exquisite a manner, and with such remarkable delicacy, that three or four of these sides laid upon one another, are not thicker than a leaf of common paper; and because the entrance of the cell, which is adapted to the size of the bee, would, on account of this delicacy, be subject to break, they strengthen the entrance of each cell with a border of wax.

We have already observed, that the bees which build the cells work but a little while at a time; but it is different with regard to those that polish them, for they work a long while, and with great expedition, never intermitting their labour, unless it be to carry out of the cell the particles of wax taken off in the polishing: and, to prevent this wax from being lost, other bees stand ready to receive it from the polishers, and carry it to some other part in order to its being employed.

Each comb has two rows of cells opposite to each other, which have their common bases. The thickness of each comb is something less than an inch; and, consequently, the depth of each cell about five lines; but at the same time the breadth of each is little more than two.

All the combs are constructed with cells of this size, except a small number of others in some par-

BEE

ticular parts of the hive, which are larger, and appropriated to the lodging eggs, that afterwards become drones, or male bees.

There are also, in some parts of the hive, three or four cells bigger than the others, and constructed in a different manner. They are of a spheroidal figure, open in the inferior part, and attached to the extremities of the combs.

When the cells are completed, the queen takes possession of those she likes best to deposit her eggs in, and the rest are left to be filled with honey. She lays one egg in each cell, and sometimes more than an hundred of those eggs in a day; but what is still more remarkable, she lays those eggs which are to produce common bees in cells of the common shape and size, those that are to become drones or males, in the cells of a larger size, and deposits those which are to become females, like herself, in the spheroidal cells already described.

These eggs, after lying some time in the cells, are hatched into maggots, and fed with honey ten or twelve days, after which the other bees close up the cells with a thin piece of wax; and under this covering they become gradually transformed into bees, in the same manner as silk-worms are into butterflies. Having undergone this change, the young bees pierce through their waxy doors, wipe off the humidity from their little wings, take their flight into the fields, rob the flowers of their sweets, and are perfectly acquainted with every necessary circumstance of their future conduct. As to the males or drones, which are destined only to propagate their species, they live very comfortably for about three months after they are hatched; but when that time is over, and the females are impregnated, the common bees either kill them, or drive them from the hive, as burdensome to the community, and not a drone is to be found till the next season.

The method in which the bees collect their wax and honey deserves to be a little explained. At the bottom of all flowers there are certain glands which contain more or less honey, that is, the most exalted particles of the sugary juices of the plant. These juices the bee sucks up with her proboscis or trunk abovementioned, and draws it into its mouth; and when it has thus taken a sufficient quantity into its stomach, it returns to the hive, and discharges the honey into the common magazine.

When the cells prepared to receive it are full, the bees close up some with wax till they have occasion for the honey; the rest they leave open, to which all the members of the society resort, and take their repast with a very instructive moderation.

It is an excellent observation of a modern author, that the hive is a school to which numbers of people ought to be sent; prudence, industry, benevolence, public spiritedness, economy, neatness, and temperance, are all visible among the bees.

BEE

These little animals are actuated by a social spirit, which forms them into a body politic, intimately united, and perfectly happy. They all labour for the general advantage; they are all submissive to the laws and regulations of the community: having no particular interest, no distinction but those which nature or the necessities of their young have introduced amongst them. We never see them dissatisfied with their condition, or inclinable to abandon the hive in disgust, to find themselves slaves or necessitous: on the contrary, they think themselves in perfect freedom and perfect affluence; and such indeed is their real condition. They are free, because they only depend on the laws; they are happy, because the concurrence of their several labours inevitably produces abundance, which contributes to the riches of each individual. Let us compare human societies with this, and they will appear altogether monstrous. Necessity, reason, and philosophy, have established them for the commendable purposes of mutual aid and benefits: but a spirit of selfishness destroys all; and one half of mankind, to load themselves with superfluities, leave the other destitute of common necessities.

Wax is composed of the farina, or dust, formed on the apices of flowers. This the bees collect, and with their fore-feet and jaws, roll up into little balls, which they convey, one at a time, to the feet of their middle legs, and from thence to the middle joint of their hind legs, where there is a small cavity like a spoon, to receive the burden. When those bees, who are employed in collecting the wax, return to the hive, they are assisted by their companions in discharging their load, who by little and little pick off the wax from their legs, and convey it to the common treasure. With this they build their combs, observing a wonderful frugality, not the least grain of it being wasted or neglected.

Considering the advantages arising from the labours of bees, is it not strange that our country-people are not more solicitous about the preservation and increase of these animals? It is certain they would multiply prodigiously with proper management; and we might, upon a moderate computation, have five thousand times as much wax and honey produced in this kingdom as we have at present. Some attempts of this kind have already been made in our own country, and there is not the least reason to doubt but they will, if pursued, be attended with success. The first method we shall mention of this kind is that of the Rev. Mr. Stephen White, which he calls collateral beehoxes; an invention by which part of the honey and wax may be taken without injuring the bees.

Manner of constructing a single BEE-BOX.—It may be made of deal, or any other boards, well seasoned, that are not apt to warp or split. The boards should be near an inch thick: let it be

BEE

eight inches and a half in height and breadth, every way, measuring within, and including the space the thin boards take up at the ends, as if there were no such boards: with these dimensions it will contain about a peck and one pint. The box is in figure four square. The front part must have a door cut in the middle of the bottom edge, about four inches wide, and half an inch in height, which will give free liberty to the bees to pass through, yet not be large enough for their enemy, the mouse, to enter. In the back part you must cut a hole with a rabbit in it, in which you are to fix a pane of the clearest and best crown-glass, about five inches in length, and three in breadth, and fasten it with putty. Let the top of the glass be placed as high as the roof within-side, that you may see the upper part of the combs, where the bees with their riches are mostly placed. You will, by that means, be better able to judge of their state and strength, than if your glass was fixed in the middle. Such as are desirous of seeing more of the bees works, may make the glass as large as the box will admit, without weakening it too much; which may be prevented by nailing a little slip of board cross the bottom. The glass must be covered with a thin piece of board, by way of shutter, which may be made to hang over the glass, by a piece of tape going through the upper part of the shutter, and fastened on the top of the box, by thrusting both ends into a gimlet hole; and after driving a peg pretty hard into the hole, you may cut off the peg close to the box.

As for the two other sides of the box, which, for distinction sake, may be called the ends, they are not to be wholly enclosed. A space is to be left in each end, near an inch wide at the top, and another space more than an inch wide at the bottom; which spaces are to be extended in length the whole breadth of the box. Through these, the bees are to have a communication from one box to another. To form these communications, a thin piece of slit deal must be let into the edges of the front and the back boards, so as to be flush with the edges of those boards.

In the next place you are to provide a piece of slit deal, full half an inch thick, and large enough to cover one of the ends, but to be used indifferently, sometimes at one end, and sometimes at the other; for which reason it is not to be nailed, but tied on, in the following manner, viz. Take about three quarters of a yard of pretty strong tape, which will be found better than packthread, because it is less apt to relax and slacken. Fix one end of the tape in the front board, about six inches above the mouth, and directly over the middle of it. Let this end of the tape be fastened in a gimlet-hole, with a peg drove hard in, and then cut off close to the board, as was directed for the shutter. You are next to bore a hole on each side of your glass,

fix inches and a half from the bottom of the box : into each of these holes drive a peg, which may stand out more than an inch from the box. Let the pegs be made of ash, which is a tough wood, and let one end of them be flat, that you may screw them out or in the more conveniently. When this is done, take your loose end-board, and set it in its proper place, so that it may cover one of the ends, it matters not which : then drawing your tape as tight as you can over it, fasten the end of it to one of the pegs by the side of the glass. This will confine your end-board, and keep the upper part of it close to the box : and if the lower part should gape a little, or start from the box, you may keep it tight by a nail or two drove so gently into the stool, on which the box is placed, that you may, whenever you have occasion, draw them out with your fingers ; or, if you like it better, you may add another tape, with pegs as before, to go cross the lower part of the end-board.

The gimlet holes need not be carried quite through the board, and it is better they should not ; for if any part of the string appears within the box, it will give offence to the bees, and cost them a great deal of pains to pull it to pieces.

You have now only to fix a stick, crossing the box from end to end, about three inches from the bottom, to be a stay to the combs : and when you have painted the whole, to make it more durable, your box is finished.

The judicious bee-master will here observe, that the form of the box is as plain as it is possible for it to be. It is little more than three square pieces of board nailed together : so that a poor cottager, who has but ingenuity enough to saw a board into given dimensions, to square it exactly, and to drive a nail, may make his own boxes well enough, without the help or the expence of a carpenter. See Plate XX. *fig. 3.* where D is the front of a single box, E the back, and F the end.

Having thus constructed the boxes, it will in the next place be necessary to describe the method of driving a swarm into them. In order to this, you are to take a box, with one end-board tied to it (as before directed) on your right hand, and another box, with the end-board tied to it on your left hand ; set these together, leaving the communications open from one box to another : then tie the boxes together as fast as you can, with a string going five or six times round them. The boxes should not be tied till you are just going to use them, because the string will grow slack with standing, and then the boxes will be apt to slip one from the other, as you handle them.

Be careful to tie the shutters close to the glass, that the light may not enter : for the bees seem to look upon the light as a hole or breach in their house, and, on that account, may not so well like their new habitation. But the principal thing to

be observed, at this time, is to cover the boxes, as soon as ever the bees are hived, with a linen cloth thrown loosely over them ; and it may be proper also to lay some green boughs upon them to protect them from the piercing heat of the sun. Boxes will admit the heat much sooner than straw-hives ; and if the bees find their house too hot, they will be wise enough to leave it. In all other respects, they are to be hived in boxes, after the same manner as in common hives, which being well known, no particular directions need be given concerning it.

When the bees are thus hived in two boxes, and placed in the evening where they are to remain, the string which tied the two boxes together may be taken off, and the shutter of your glass being at liberty, observe which of the boxes the bees have made choice of for their present residence, and stop the mouth of that box with a slip of board, so that they may work only out of the empty box ; for they will fill the former with their works before they begin in the latter. When you find they have begun in the second box, it will be proper to give them a third, which is done in this manner. Take a thin knife, and cut through the refinous substance, with which the bees will now have joined the end-board to the box ; then loosening the tape that ties the board, thrust gently a sheet of double tin between the box and the end-board, taking away the latter, and placing an empty box in the room of it : this done, draw away the tin with a gentle hand, and thrust the new box close to the other. You must also remember that the mouth of this third box must be stopped like the first, that the entrance may be only in the second or middle box. See Plate XX. *fig. 3.* where G, G, G, are three boxes joined together. H the tape which ties the end-boards, I the tin stopping the communication.

About the middle of August, you will easily discover through your glasses, which of your colonies you may lay under contribution. Such as have filled three boxes will readily yield you one of them : and it will be best to take the box where there are fewest bees, because the queen-bee is not likely to be there. The most proper time is about three or four o'clock in the afternoon ; when the operation may be easily performed in the following manner : Open the mouth of the box you are going to seize ; or, which may be better, that half of it which is furthest from the middle box : then, with a thin knife, cut through the resin with which the bees have joined this box to the middle one, till you find you have separated them ; after which thrust your sheet of tin gently between the boxes, and your work is done. The communication being thus stopped, the bees in the two boxes, where in all probability the queen is, will be a little disturbed at the operation, but those in the single

single box will appear distracted. They soon become sensible that their sovereign is not among them; and accordingly issue out at the new door in a visible rage and disorder; but this is quickly over; for they soon discover their companions, and fly to them with eager haste, at the usual mouth of the middle box, forgetting, in the midst of their transports, the loss of the riches they have left behind them. You may now carry off the prize without molestation, placing an end-board in the room of the box you have taken, drawing away your tin, and fastening the board with tape, as before directed. See Plate XX. *fig. 3.* where K represents the hole half open, and the bees issuing out of the box to be taken away.

By this method, large quantities of wax and honey may be collected, without destroying the bees, while your stock will be every year increased by swarms, and all your colonies well stocked with bees.

Another invention for saving the lives of bees, and increasing the quantity of wax and honey, has very lately been laid before the Society for the Encouragement of Arts, &c. by Mr. Thorley, and obtained their approbation.

Description of Mr. Thorley's BEE-HIVE.—This ingenious and assiduous gentleman, having, from near sixty years experience, found that his bee-hives would be productive of much greater profit to the owners of bees, and also render that cruel and ungenerous practice of destroying these animals not only unnecessary, but pernicious, presented a bee-hive of this construction to the Society of Arts, &c. in the Strand, who readily purchased another of his hives filled with honey, &c. that they might be inspected by the curious, and brought into universal use; and from this bee-hive the view on Plate XX. *fig. 4.* was drawn. The Society, persuaded that the invention would prove of the greatest advantage to this country, have published a premium of two hundred pounds, in order to introduce either Mr. Thorley's, or some other method of a similar kind, whereby much larger quantities of honey and wax might be procured, and, at the same time, the lives of these laborious and useful insects preserved.

The bottom part, marked A, is an octangular bee-box, made of deal boards, about an inch in thickness, the cover of which is about 17 inches in diameter, but the internal part only $15\frac{1}{2}$, and its height ten inches. In the middle of the cover of this octangular box is a hole, which may be opened or shut at pleasure, by means of a slider *d*. In one of the pannels is a pane of glass, covered with a wooden door, *b*. The entrance, *a*, at the bottom of the box is about three inches and a half broad, and half an inch high. Two slips of deal, about half an inch square, cross each other in the center of the box, and are fastened

to the pannels by means of small screws. To these slips the bees fasten their combs.

In this octangular box the bees are hived, after swarming in the usual manner, and there suffered to continue till they have built their combs, and filled them with honey, which may be known from opening the door, and viewing their works through the glass pane, or by the weight of the hive. When the bee-master finds his laborious insects have filled their habitation, he is to place a common bee-hive of straw, represented at B, made either flat at the top, or in the common form, on the octangular box, and draw out the slider, by which a communication will be opened between the box and the straw hive; the consequence of which will be, that those laborious insects will fill this hive also with the product of their labours. When the bee-master finds the straw hive is well filled, he may push in the slider, and take it away, placing another immediately in its room, and then drawing out the slider. These indefatigable creatures will then fill the new hive in the same manner. By proceeding in this method, Mr. Thorley assured the Society that he had taken three successive hives, filled with honey and wax, from one single hive, during the same summer; and that after he had laid his insects under so large a contribution, the food still remaining in the octangular box was abundantly sufficient for their support during the winter. He added, that if this method was pursued in every part of the kingdom, instead of that cruel method of putting the creatures to death, he was persuaded from long experience, that wax would be collected in such plenty that candles might be made with it, and sold as cheap as those of tallow are at present.

Mr. Thorley has also added another part to his bee-hive, which cannot fail of affording the highest entertainment to a curious and inquisitive mind. It consists of a glass receiver, represented at D, 18 inches in height, 8 inches in diameter at the bottom, and in the greatest part 13. This receiver has a hole at the top, about an inch in diameter, through which a square piece of deal E is extended to nearly the bottom of the vessel, having two cross bars to which the bees fasten their combs. When the bees have filled their straw hive, (which must have a hole in the center C, covered with a piece of tin) Mr. Thorley places the glass-receiver upon the top of the straw hive, and draws out the piece of tin: the bees, now finding their habitation enlarged, pursue their labours with such alacrity, that they fill this glass hive likewise with their stores. And as this receptacle is wholly transparent, the curious observer may entertain himself with viewing the whole progress of their works. One of the hives, now deposited at the Society's rooms in the Strand, is filled with the produce of the labours of those insects; and the glass-hive is supposed to contain

contain near thirty pounds of honey. See a further account of managing these useful creatures, and the nature of their productions, under the articles SWARM, HIVE, HONEY, WAX, &c.

BEE-BREAD, a substance found in the cells of bees, and which is thought necessary to their subsistence. It is nothing more than wax itself unprepared.

BEECH, *Fagus*, in botany, an amentaceous tree, producing male and female flowers. The male flowers are apetalous, composed of an empalement of one leaf, containing several stamina, and are collected into globular heads; the female flowers are also destitute of petals, but consist of a single calyx, which contains a germen, which afterwards becomes a roundish capsule, opening in three cells containing in each a triangular nut.

There is but one species of this tree at present known, (except two varieties with striped leaves, which are accidental) and a beech which grows in North America; but the plants which have arisen from the seeds thereof, are no way distinguishable from the common sort.

This tree is propagated from its seed, (called mast) which must be gathered about the latter end of September, or beginning of October, at which time it is ripe and begins to fall; and is the proper and most natural season for sowing them, though it may be done any where between the time of gathering and the month of February. A small spot of ground will be sufficient to raise a great number of trees from seeds; the beds must be kept clear of weeds, and managed as the ash. See ASH.

This tree will grow to a considerable stature, though the soil be stoney and barren; as also, upon the declivities of hills and chalky mountains, where they will resist the winds better than most other trees; but then the nurseries for the young plants ought to be one and the same sort of soil, for if they are raised in a good soil, and a warm exposure, and afterwards transplanted into a bleak barren situation, they seldom thrive, which is the case in most other trees.

The beech is very proper to form large hedges, to surround plantations, &c. and may be kept in a regular form by clipping twice a year, especially if they shoot strong. The shade of this tree is very injurious to most sort of plants, which grow near it, but is generally believed to be very salubrious to human bodies.

This timber is of great use to turners for making trenchers, dishes, trays, buckets, and likewise to joiners for bedsteads, stools, planes, &c. also for making rims of wheels for corn-mills, water-engines, and divers other purposes. The mast, or fruit of the beech-tree, is very good to fat hinds or deer; it also affords a sweet oil.

BEECH-MAST, the fruit of the beech-tree, excellent for the fattening of hogs, &c.

BEER, a common and well known liquor, made with malt and hops, and used in those parts of Europe where vines will not grow, and where cyder is scarce. See the articles MALT, BREWING, &c.

It is chiefly distinguished from ale by the quantity of hops, which is greater in beer, and thereby renders the liquor bitterer, and fitter to keep.

There are various differences in beers, proceeding from the ways of brewing, from the different countries or climates, from the water that is used, from the time spent about them, from the ingredients made use of, and the proportions of these ingredients.

That beer is reckoned the best which is clear, and of a pale colour, of a pungent and agreeable taste, that sparkles upon being poured into a glass, and is neither too old nor too new.

Agre BEER is used by callico-printers, chemists, lapidaries, scarlet-dyers, vinegar-merchants, and white-leadmen.

BEER, among weavers, a term that signifies nineteen ends of yarn, running all together the whole length of the cloth.

BEER-MEASURE. See MEASURE.

BEESTINGS, a term used by country people for the first milk taken from a cow after calving.

BEET, *Beta*, in botany. See BETA.

BEETLE, *Scarabeus*, in the history of insects. See the article SCARABÆUS.

BEETLE also denotes a wooden instrument for driving piles, &c.

It is likewise called a stamper; and by paviors a rammer.

BEGHARDI, *Beguardi*, a certain sect of heretics, which arose in Germany, and in the Low-Countries, about the end of the thirteenth century. They made profession of monastical life, without observing celibacy; and maintained, if they are not scandalized by the monks, that man could become as perfect in this life as he shall be in heaven; that every intellectual nature is of itself happy, without the succour of grace; and that he who is in this state of perfection ought to perform no good works, nor worship the host.

BEGLERBEG, a governor of one of the principal governments in the Turkish empire. There are two sorts of beglerbegs; the one have a certain revenue assigned upon the cities, boroughs, and villages of their government, which they raise by power of the commission granted to them by the sultan; the others have a certain rent paid by the treasurer of the grand seignior. They are become almost independent, and have under their jurisdiction several sangiacs, or particular governments, and beys, agas, and other officers who obey them.

BEGUINS, congregations of devout young women, who maintain themselves by the work of their hands, leading a middle kind of life between the secular and religious. These societies consist of several houses, placed together in one inclosure, with one or more churches, according to the number of beguins.

There is in every house a prioress, without whose leave they cannot stir out. Their vow is conceived in these terms: "I promise to be obedient and chaste, as long as I continue in this beguinage." They observe a three years noviciate, before they take the habit, and the rector of the parish is the superior, but can do nothing without the advice of eight beguins.

They are established in several parts of Flanders.

BEHEN, in pharmacy, a name appropriated to two roots, very different from one another in shade, colour, and their whole external appearance, and distinguished by the names of white and red behen.

We have them both from the Levant, and they seem to be produced in many parts of the East; but no where in such plenty as about the foot of Mount Lebanon.

The same virtues are attributed to both kinds of behen, but the white is supposed to possess them in the greatest degree; they are said to be great cordials and restoratives, and to be good in nervous complaints.

BEIRAM, or **BAIRAM**, a Turkish word which signifies a solemn feast. The Turks celebrate two beirams; the greater, which falls on the tenth day of the last month of the Arabic year, which is the month of pilgrimage; and the lesser, which ends the feast of the month Rammadan, and falls on the first day of the month Scheval. This latter is celebrated at Constantinople, and elsewhere, with great rejoicings, because it puts an end to their fasting; and for this reason it is vulgarly called the Easter of the Turks.

BEL, or **BELUS**, the supreme god of the ancient Chaldeans or Babylonians. He was the founder of the Babylonian empire, and is supposed to be the Nimrod of Scripture, and the same as the Phœnician Baal.

This god had a temple erected to him in the city of Babylon, on the very uppermost range of the famous tower of Babel, or Babylon, wherein were many statues of this deity, and one, among the rest, of massy gold, forty feet high. The whole furniture of this magnificent temple was of the same metal, and valued at eight hundred talents of gold.

This temple, with its riches, was in being till the time of Xerxes, who, returning from his unfortunate expedition into Egypt, demolished it,

and carried off the immense wealth contained in it.

It was the statue of this god which Nebuchadnezzar, being returned to Babylon, after the end of the Jewish war, set up, and dedicated in the plain of Dura; the story of which is related at large in the third chapter of Daniel.

BEL and the **DRAGON**, the history of, an apocryphal, and uncanonical, book of Scripture. It was always rejected by the Jewish church, and is extant neither in the Hebrew nor the Chaldæe language; nor is there any proof that it ever was so. St. Jerom gives it no better title than the Fable of Bel and the Dragon. It is however permitted to be read, as well as the other apocryphal writings, for the instruction and improvement of manners.

BELATUCADRUS, or **BELLUTUCADRUS**, a deity of the ancient Britons, particularly the Brigantes, or inhabitants of Cumberland.

He appears to have been the same as Mars; and it is probable the name might be taken from Bel, or Baal, the great idol of the Assyrians, which, according to Cedrenus, was the same as Mars.

BELAYING, amongst seamen, fastening a small rope; as there are other phrases appropriated to larger ropes, as bend, bit, stopper, &c.

BELEMNITES, in natural history, a kind of fossil substance, with regard to whose origin naturalists are divided. It is generally called the thunder-bolt. See Plate XVII. fig. 5.

The word is formed from the Greek, *βελωνιον*, a dart.

The shape of the belemnites is sometimes conical, sometimes cylindrical, and commonly consists of a black and horny substance. The inward parts consist of rays, and there is generally a cell at the large end, and a furrow that runs from the top to the bottom. Dr. Plott informs us, that when the belemnites are rubbed against each other, or are scraped with a knife, they have the smell of rasped horn, and that their texture consists of small threads running like rays from the centre, or rather from the axis of the stone to the surface: when burned they have likewise a smell like that of horn; and the greatest he found was somewhat above four inches in length, and about an inch and a quarter in thickness.

They are found in all sorts of strata, in clay, gravel, beds of stone, and often in loose flints. They are sometimes found covered with a sparry crust of a different texture from the body of the mass.

BELENUS, the tutelar deity of the ancient inhabitants of Aquileia in Italy, of the Gauls, and of the Illyrians. He was the same as Apollo, or the Sun; as we learn from Julius Capitolinus, who relates, that when Maximinus in vain besieged Aquileia, he sent ambassadors into the town, who had

had almost persuaded the people to surrender, had not Menophilus and his colleague opposed it, telling them, that the god Belenus had promised them the victory over Maximinius. The historian adds, that the soldiers of Maximinius afterwards gave out, that Apollo fought against them.

BELIEF, in a general and natural sense, signifies a persuasion or strong assent of the mind to any proposition; but, in a more restrained and technical sense, it imports that kind of assent which is founded on the authority or testimony of some persons attesting the truth of any matter proposed.

BELIEF is generally distinguished into divine and human, not with regard to the proposition believed, but with regard to the testimony on which we believe it. When God reveals any thing to us, this gives us the testimony of divine belief. See the article **FAITH**.

But what man only acquaints us with, produces only a human belief. See the article **EVIDENCE**.

BELL, a well known machine, ranked by musicians among the musical instruments of percussion.

The metal of which a bell is made, is a composition of tin and copper, or pewter and copper: the proportion one to the other is about twenty pounds of pewter, or twenty-three pounds of tin to one hundred weight of copper.

The sound of a bell consists in a vibratory motion of its parts, much like that of a musical chord. The stroke of the clapper must necessarily change the figure of the bell, and of a round make it oval; but the metal having a great degree of elasticity, that part will return back again which the stroke drove farthest off from the center, and that even some small matter nearer the center than before; so that the two parts which before were extremes of the longest diameter, do then become those of the shortest: and thus the external surface of the bell undergoes alternate changes of figure, and by that means gives that tremulous motion to the air in which the sound consists.

Diving BELL. See the article **DIVING**.

BELL-FOUNDRY. See **FOUNDRY**.

BELL-FLOWER, *Campanula*, in botany; see the article **CAMPANULA**.

BELLA-DONNA, in botany, a genus of the pentandria monogynia class of plants, called by Linnaeus *atropa*. See **ATROPA**.

BELLING of *Hops* denotes their opening and expanding themselves. See **HOPS**.

BELLIS, *DAISY*, in botany. See **DAISY**.

BELLON, a distemper common in countries where they smelt lead ore; as also among plumbers and painters.

It is attended with languor, intolerable pains and sensation of gripings in the belly, and generally costiveness.

Beasts, poultry, &c. as well as men, are subject to this disorder: hence a certain space round the smelting houses is called bellon-ground, because it is dangerous for an animal to feed upon it.

BELLONA, the pagan goddess of war. She is joined by Homer with Mars, the god of war.

Bellona is called by the Greeks *Ἐνυο*, Enyo. Some make her the mother, others the sister, and others the wife of Mars, who is styled Enyalios upon one or other of those accounts. Hesiod says, she was the daughter of Phorcys and Ceto.

As the sun, among other names, is supposed to have been worshipped under that of Mars, so it is probable Bellona represented the moon.

BELLONARI, in Roman antiquity, the priests of Bellona, who, in honour of that goddess, used to make incisions in their body; and, after having gathered the blood in the palm of their hand, gave it to those who were partakers of their mysteries.

BELLONIA, in botany, a pentandrious plant common in several parts of the American islands; it hath a woody stem, which rises ten or twelve feet high, sending out many lateral branches, which are garnished with oval rough leaves, placed opposite: the flowers come out from the wings of the leaves in loose panicles: these are wheel-shaped, of one plate, and divided into five parts; the germen is situated under the receptacle of the flower, and is succeeded by an oval capsule ending in a point, which is full of small round seeds. This plant is propagated by seeds; but, being a native of the hot countries, it requires a stove in this climate to preserve it.

BELLOWING, among sportsmen, denotes the noise of roes in rutting-time.

BELLOWS, a machine so contrived as to agitate the air with great briskness, expiring and inspiring the air by turns, and that only from enlarging and contracting its capacity.

BELLY, in anatomy, the same with what is more usually called abdomen, or rather the cavity of the abdomen. See the article **ABDOMEN**.

BELOMACY, a sort of divination by means of arrows, practised in the East, and particularly in Arabia.

Belomancy has been performed different ways, whereof one was this: suppose a parcel of arrows, eleven or more of them, being put into a bag; these were afterwards drawn out, and according as they were marked or not, they judged of future events.

BELT, *Balteus*, in the military art, a leathern girdle for sustaining the arms, &c. of a soldier.

BELTS, in astronomy, two zones, or girdles, surrounding the body of the planet of Jupiter, more lucid than the rest, and of unequal breadth. See **JUPITER**.

BELVIDERE, in the Italian architecture, &c. denotes

BEN

denotes either a pavilion on the top of a building, or an artificial eminence in a garden; the word literally signifying a fine prospect.

BEN, BEEN, or BEHEN. See BEHEN.

BENCH, or BANC, in law; see BANC.

Free BENCH signifies that estate in copyhold lands, which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor. As to this free-bench, several manors have several customs; and in the manors of East and West Enbourne, in the county of Berks, and other parts of England, there is a custom, that when a copyhold tenant dies, the widow shall have her free-bench in all the deceased husband's lands, whilst she lives single and chaste; but if she commits incontinency, she shall forfeit her estate: nevertheless, upon her coming into the court of the manor riding on a black ram, and having his tail in her hand, and at the same time repeating a form of words prescribed, the steward is obliged, by the custom of the manor, to re-admit her to her free-bench.

Widow's BENCH. See WIDOW.

BENCHERS, in our inns of court, the senior members of the society, who are invested with the government thereof.

BEND, in heraldry, one of the nine honourable ordinaries, containing a third part of the field when charged, and a fifth when plain. It is sometimes, like other ordinaries, indented, ingrailed, &c. and is either dexter or sinister.

BEND Dexter is formed by two lines drawn from the upper part of the shield on the right, to the lower part of the left, diagonally. It is supposed to represent a shoulder-belt, or a scarf, when worn over the shoulder.

BEND Sinister is that which comes from the left side of the shield to the right; this the French heralds call a barre.

BENDING, amongst seamen, the fastening two ends of rope to one another; to fasten a sail to its yard or stay; to fix the cable to the anchor. See CABLE, CLENCH, SAIL.

BENDS, in naval architecture, the thickest and strongest planks in a ship, reaching from end to end at her extreme breadth: when a merchant-ship is laden no deeper than to bring her bends down to the surface of the water, she is said to be in good sailing order.

BENDY, in heraldry, is the field divided into four or more parts diagonally, and varying in metal and colour.

The general custom of England is to make an even number, but in other countries they regard it not, whether even or odd.

Counter BENDY is used by the French to express what we ordinarily call bendy of fix per bend sinister, counter-changed.

BEN

Barry BENDY. } See the articles } BARRY.
Paly BENDY. } PALY.

BENEDICITE, among ecclesiastical writers, an appellation given to the Song of the three children in the fiery furnace, on account of its beginning with the word Benedicite.

BENEDICTINS, in church history, an order of monks who profess to follow the rules of St. Benedict.

The Benedictins, being those only that are properly called monks, wear a loose black gown, with large wide sleeves, and a capuche, or cowl on their heads, ending in a point behind. In the canon-law, they are styled black-friars, from the colour of their habit.

BENEDICTION, or BLESSING. The Hebrews, under this name, understand the present usually sent from one friend to another, as also the blessing conferred by the patriarchs, on their death-beds, upon their children.

The privilege of benediction was one of those early instances of honour and respect paid to bishops in the primitive church. The custom of bowing the head to them, and receiving their blessings, was become universal. In the western churches there was anciently a kind of benediction which followed the Lord's prayer; and after the communion the people were dismissed with a benediction.

BENEFICE, *Beneficium*, in an ecclesiastical sense, a church endowed with a revenue for the performance of divine service; or the revenue itself assigned to an ecclesiastical person, by way of stipend, for the service he is to do that church.

All such preferments, except bishoprics, are called benefices; and all benefices are, by the canonists, sometimes styled dignities: but we now ordinarily distinguish between benefice and dignity, applying dignity to bishoprics, deaneries, archdeacons, and prebendaries; and benefice to parsonages, vicarages, and donatives.

Benefices are divided by the canonists into simple and sacerdotal; in the first there is no obligation but to read prayers, sing, &c. the second are charged with the cure of souls, or the direction and guidance of consciences; such are vicarages, rectories, &c.

The Romanists again distinguish benefices into regular and secular.

Regular or titular benefices are those held by a religious, or a regular, who has made profession of some religious order: such are abbies, priories, conventuals, &c. or rather a regular benefice is that which cannot be conferred on any but a religious, either by its foundation, by the institution of some superior, or by prescription: for prescription, forty years possession by a religious, makes the benefice regular.

Secular

Secular benefices are only such as are to be given to secular priests, that is, to such as live in the world, and are not engaged in any monastic order. All benefices are reputed secular, till the contrary is made to appear. They are called secular benefices, because held by seculars; of which kind are almost all cures.

Some benefices, regular in themselves, have been secularized by the pope's bull.

The canonists distinguish three manners of vacating a benefice; viz. *de jure*, *de facto*, and by the sentence of a judge.

A benefice is vacated *de jure*, when the person enjoying it is guilty of certain crimes expressed in those laws, as heresy, simony, &c.

A benefice is vacated *de facto*, as well as *de jure*, by the natural death, or the resignation of the incumbent; which resignation may be either express, or tacit, as when he engages in a state, &c. inconsistent with it, as, among the Romanists, by marrying, entering into a religious order, or the like.

A benefice becomes vacant by the sentence of a judge, by way of punishment for certain crimes, as concubinage, perjury, &c.

It is observed, that anciently there were five ways by which benefices were acquired; by the nominative, as in royal nomination; by the genitive, as when the children of great men, &c. are provided of benefices by their birth; by the dative, as when speaking of a benefice, it is said *dato*, and *dabitur vobis*; by the accusative, as where, by virtue of an accusation, either true or false, an incumbent is dispossessed, and another admitted; by the ablative, as when benefices are taken away by force from the poor and helpless; but the vocative, which is the most just and legitimate, is out of use.

A BENEFICE in *Commendam* is that, the direction and management of which, upon a vacancy, is given or recommended to an ecclesiastic, for a certain time, till he may be conveniently provided for. See the articles REGULAR and SECULAR.

BENJAMIN-TREE, *Benzoine*, in botany, a tree which grows naturally in North America. It rises to the height of eight or ten feet, dividing into many branches, which are furnished with oval spear-shaped leaves, smooth on their upper surface, but with many transverse veins on their under side: these leaves are deciduous, and the flowers are herbaceous. For their generical characters, see the article LAURUS, of which this plant is a species.

The gum Benjamin, or Benzoine, is the juice of this tree, and exudes from incisions, in form of a thick white balsam: if collected as soon as it has grown somewhat solid, it proves internally white like almonds; and hence is called *benzocanygedaloides*; if suffered to lie long exposed to the sun

and air, it changes more and more to a brownish, and at last to a quite reddish brown colour.

This resin is moderately hard and brittle; and yields, on being rubbed or warmed, an extremely agreeable sweet smell. It totally dissolves in spirit of wine into a blood-red liquor, leaving only the impurities, which amount commonly to no more than about a scruple, upon an ounce: to water it gives out a portion, not of gummy or mucilaginous, but of saline matter, of a peculiar kind, volatile and sublimable in the fire, and which indeed is most effectually separated by dry sublimation; and hence called flowers of benzoine.

Some prepare the flowers from benzoine by itself, reduced into gross powder; others mix it, in fine powder, with an equal quantity of washed sand. An earthen pot or jar is filled with the matter to one half or one fourth its height, then covered with a conical paper cap, which, as soon as any considerable quantity is judged to be collected, is removed, and supplied by another, and the process continued till nothing more will sublime: the remaining benzoine, which appears of a blackish brown colour, may still be used, if no sand has been mixed, in compositions for yielding an odorous smoke, and for other like purposes. This method is not a little troublesome, the quantity of flowers obtained by it small, and the flowers themselves commonly tinged of a yellowish or even a brown colour from some of the oil of the benzoine arising with them; for as the sand grows continually hotter and hotter, it is scarce possible to prevent the heat increasing so far as to elevate a portion of the oil.

Benzoine and its flowers are employed medicinally for resolving and attenuating viscid juices, particularly in disorders of the breast: but the principal use of this fragrant resin is in perfumes, and as a cosmetic, for softening and smoothing the skin. For this last purpose, the benzoine is dissolved in spirit of wine, with the addition sometimes of Storax: the solution, mixed with water, forms a white liquor called virgins milk, which on standing slowly deposits a fine white magistery. Some add to the tincture of benzoine, a tincture or solution of litharge in vinegar; and thus obtain a compound virgins milk and magistery, less innocent than those from benzoine alone. A small quantity of the oil of benzoine heightens the smell of perfumes, and corrects rancid unguents and balsams.

BER, in botany, that species of the jugubertree which produces the gum lacca. See ZIZIPHUS.

BERAMS, a coarse cloth, all made of cotton thread, which comes from the East Indies, and particularly from Surat. There are white plain berams, and others striped with colours. The white are about eleven yards long, and about a yard wide; the

the red are fifteen yards long, and something less than a yard wide.

BERBERIS, the barberry-bush, in botany, a shrub having fibrous, yellowish, creeping roots, from which many stalks arise to the height of nine or ten feet, whose bark is whitish without, and yellow within-side, and is beset with sharp thorns. The leaves are small, oblong, narrow at the bottom, but broader at the top: these are of a smooth green, slightly serrated at their edges, and have an acid taste. The flowers come out from the wings of the leaves, in small ramose bunches; these are yellow and hexapetalous, and when decayed are succeeded by cylindrical umbilicated berries, of a red colour, containing in each two oblong seeds: it flowers in May, and the fruit is ripe in September.

This plant is generally propagated from suckers, which it puts out in great plenty from the roots; but those plants are apt to put out a greater number of suckers than is required; to prevent which, it is not a bad method to raise them by laying: the best time for this operation is in autumn, when their leaves begin to fall. The young shoots of the same year are to be preferred; these by the next autumn will be well rooted, when they may be taken off, and planted where they are designed to remain.

The fruit of this shrub is a mild astringent acid, acceptable to the stomach, and of great medicinal efficacy in hot bilious disorders, and a colliquative or putrid disposition of the humours. Prosper Alpinus informs us, that the Egyptians employ, in ardent and pestilential fevers and in fluxes, a diluted juice of the berries, prepared by macerating them in about twelve times their quantity of water, for a day or a night, with the addition of a little fen-nel seed, or a piece of bread, and then pressing out and straining the liquor, which is sweetened with sugar, or sugar of roses, or syrup of citrons, and given the patient plentifully to drink. Among us, these berries are commonly made into jelly, by boiling them with an equal weight of fine sugar, over a gentle fire, to a due consistence, and then straining the fluid through a woollen cloth: By drying the berries, their acidity is abated, and their astringency improved.

The leaves of the barberry-bush have likewise a hot, ungrateful, refringent, acid taste, and have sometimes been employed in the same intentions as the fruit, and as an ingredient in cooling salads. The inner yellow bark, in taste austere and bitterish, is said to be gently purgative, and to be serviceable in jaundices. Mr. Ray commends, in this disease, from his own experience, a decoction in ale or other liquors, or rather an infusion in white wine, of the yellow bark both of the branches and the roots.

BERECYNTHIA, the mother of the gods, in the pagan theology; so called from Berecynthus, a mountain in Phrygia. Anchises, in Virgil, compares Rome, in her future glories, to this deity.

Gregory of Tours says there was, in his time, an idol of Berecynthia or Cybele, worshipped in Gaul, which they carried into their fields and vineyards in a cart, for the preservation of the fruits of the earth; and that they marched in procession before the deity, singing and dancing. One day this holy man, touched with the impiety of these idolaters, put up a prayer to heaven, and made the sign of the cross; whereupon the idol immediately fell to the ground, the cart and oxen remaining immoveable: the people whipped the oxen to make them go forwards, but all to no purpose. Upon this, four hundred of the multitude cried out, If she be a deity, let her raise up herself, and make the oxen go on: but this not happening, they all turned Christians. See **CYBELE**.

BERENGARIANS, a religious sect of the eleventh century, which adhered to the opinion of Berengarius, who, even in those days, strenuously asserted, that the bread and wine in the Lord's supper is not really and essentially, but only figuratively, changed into the body and blood of Christ.

His followers were divided in opinion as to the eucharist: they all agreed that the elements are not essentially changed in effect: others admitted a change in part; and others an entire change, with this restriction, that to those who communicated unworthily, the elements were changed back again.

BERGAMOT, the name of a fragrant essence imported from Italy.

BERGAMOT PEAR. See **PEAR-TREE**.

BERGHMOT, an assembly, or court, held upon a hill in Derbyshire, for deciding controversies among the miners.

BERME, in fortification, a space of ground left at the foot of the rampart, on the side next the country, designed to receive the ruins of the rampart, and prevent their filling up the fosse. It is sometimes palisadoed, for the more security; and in Holland it is generally planted with a quickset-hedge. It is also called *liziere*, *relais*, *foreland*, *retraite*, *pas de fouris*, &c.

BERNARDIN MONKS, an order of religious founded by Robert Abbot of Molome: they are properly Cistercians, or Monks of Citeaux; but their order having been enlarged and amplified by St. Bernard, they were from thence called Bernardins. They follow the rule of St. Benedict, and are habited in white.

There are likewise Bernardin nuns; concerning whose institution it is related, in the Life of St. Bernard, that, in the year 1113, which was the fiftieth of the foundation of the abbey of Citeaux,

St.

St. Bernard, with thirty companions, devoted themselves in that convent to a religious life; and as several of the companions of this saint were married, and their wives likewise had resolved to quit the world, and dedicate themselves to God, a monastery was founded for them, at the request of St. Bernard, at Juilli in the diocese of Langres. The Bernardin nuns, as well as monks, are subject to the laws of the Cistercians. See CISTERCIANS.

BERNICLA. See the article **BARNACLE**.

BERRY, *Bacca*, in botany; see **BACCA**.

BERYL. See *AQUA Marina*.

BES, or **BESSIS**, in Roman antiquity, two thirds of the *as*. See the article *As*.

BES also denotes two thirds of the *jugerum*. See the article *JUGERUM*.

BESANT, or **BEZANT**, a coin of pure gold, of an uncertain value, struck at Byzantium, in the time of the Christian emperors; from hence the gold offered by the king at the altar, is called *besant*, or *bisant*.

BESANTS, in heraldry, round pieces of gold, without any stamp, frequently borne in coats of arms.

BESLERIA, in botany, a genus of didynamious plants, whose flower consists of a monophyllous calyx, which contains a single labiated petal, quinquefid and round; the filaments are four in number, two of which are longer than the others; the style is awl-shaped, and rests on a globose germ, which afterward becomes a round berry of one cell, containing many round small seeds.

These plants (of which there are three species) grow naturally in the warm parts of America, from whence the seeds have been brought to Europe, and cultivated in some curious botanical gardens. They are sown on a hot bed in the spring, and kept in the stove in winter.

BETA, beet, in botany, a plant producing petalous flowers: there are two sorts cultivated in our culinary gardens; the white beet, called *ciela*, and the red beet with a turnip root. The white beet has a round, long, white root, with large, broad, smooth, thick, succulent leaves, sometimes (as the soil and culture may vary them) of a pale, and sometimes of a deeper green, with a thick broad rib; the stalks are slender, streaked, and branched; the flowers come out in spikes at the wings of the leaves, and each consists of a five-leaved empalement, which contains five subulated filaments topped with roundish antheræ; the fruit is an unilocular capsule within the base of the calyx, and contains a single seed. The red beet hath also large, thick, succulent leaves, which are for the most part of a dark red or purple colour: the roots of this sort are large, and of a deep red colour, on which their goodness depends; for the larger these

roots grow, the more tender they will be, and the deeper their colour, the more they are esteemed.

There are several varieties of this sort, as the common red beet, the turnip-rooted red beet, and the green-leaved red beet. All the different kinds of beet are cultivated in gardens, for the use of the kitchen; but they were in greater esteem formerly than at present; however, the red beet is still in use to garnish dishes. They are propagated by sowing the seeds in March, in a deep loose soil, and when come up should be hoed out, leaving those that are to remain at about ten or twelve inches asunder: the roots will be fit for use in autumn, and continue good all the winter; but in the spring they will shoot, and become hard and stringy. The seeds of this plant, by which only it is propagated, ripen about the end of August, or beginning of September; to obtain them in perfection, some of the finest roots that have been preserved from the frosts may be replanted in March, in a well sheltered place, and let run to seed. The roots of beets have, when dry, an agreeable sweetish taste, which is totally extracted by boiling in rectified spirit; the tinctures, on standing some weeks in a cool place, deposit whitish saline concretions of a saccharine sweetness: it is said, a good sugar may be obtained from the fresh roots, by the method practised abroad as with the sugar cane.

Beets are very little used, unless in the kitchen, and chiefly the red, which is reckoned cooling and emollient.

BETEL, in botany, an Indian plant, in great use and esteem throughout the East, where it makes a considerable article of commerce.

The betel bears some resemblance to the peppertree. Its leaves are like those of ivy, only softer, and full of a red juice, which among the orientals is reputed of wonderful virtue for preserving the teeth, and rendering the breath sweet. The Indians are continually chewing these leaves, which makes their lips so red, and teeth black, a colour by them vastly preferred to the whiteness affected by the Europeans.

The consumption of betel leaves is incredible, no person, rich or poor, being without their box of betel, which they present to each other by way of civility, as we do snuff.

BETHLEHEMITES, in church-history, a religious order, called also star-bearers, *stelliferi*, because they were distinguished by a red star with five rays, which they wore on their breast, in memory of the star that appeared to the wisemen, and conducted them to Bethlehem.

There is an order of Bethlehemites still subsisting in the Spanish West-Indies, who are habited like Capuchins, with this difference, that they wear a leather girdle instead of a cord, and on the

the right side of their cloak an escutcheon, representing the nativity of our Saviour.

BETONICA, betony, in botany, a genus of didynamious plants. The common or wild sort has a thick, transverse, fibrous, hairy root, from whence proceed quadrangular knotty stalks; some of the leaves proceed from the knots, by pairs placed over-against each other, and others lay on the ground: these are oblong, villous, wrinkled, and of a darkish green colour, and crenated on their edges. The flowers grow in spikes, and are monopetalous, labiated, and of a purplish colour; the upper-lip is fulcated and reclining backward, but the lower consists of three lobes; each flower contains four subulated stamina, and the calyx is cut into five segments, from whence proceeds a pistil, fixed to the hinder part of the flower, like a nail, with four embryoes, which change to as many seeds.

Betony is common in woods and shady places in England, and flowers in June or July; it is reckoned discutient and aperient, and has been always accounted an excellent medicine for the head; the leaves reduced to powder promote sneezing, for which reason, and for its being a cephalic, it is always an ingredient in the herb-snuff. Antonius Musa wrote a treatise about it, and commends it much as a vulnerary, especially in wounds of the head; and some recommend its juice boiled up to the consistence of honey, and mixed up with a small quantity of the Peruvian balsam, as a great healer. Besides the common betony, botanists enumerate six other species, which are natives of foreign countries.

BETULA, the birch-tree; see the article **BIRCH**.

BEVEL, among masons, carpenters, joiners, and bricklayers, a kind of square, one leg whereof is frequently crooked, according to the sweep of an arch or vault. It is moveable on a center, and so may be set to any angle.

BEVEL-ANGLE, any other angle besides those of ninety or forty-five degrees.

BEVILE, in heraldry, a thing broken or opening like a carpenter's rule: thus we say, he beareth argent, a chief bevile, vert, by the name of Beverlis.

BEURERIA, the Carolina all-spice, in botany, a plant whose root is large and spreading, from which ariseth the stem, divided into many slender branches, which spread irregularly, and the bark is of a pale brown; these are furnished with broad leaves of a lanceolate oval form, and of a lively green; they stand in pairs, and are placed opposite at every joint: the flowers come out from the wings of the leaves, and are large, elegant, and of a deep but very dusky purple, composed of two series of narrow thick petals, irregularly disposed and waved;

the embryo sits beneath the flower, and supports five stigma: this afterward appears to have five cells, containing the same number of seeds.

The bark of this shrub is brown, and has a very strong aromatic scent, from which circumstance the inhabitants of Carolina gave it the name of all-spice. This plant is propagated by layers, and in a warm situation will bear the cold in this climate tolerably well.

BEWITS, in falconry, pieces of leather to which a hawk's bells are fastened, and buttoned to his legs.

BEY, among the Turks, signifies a governor of a country or town. The Turks write it *bey*, or *bek*, but pronounce it *bey*.

BEY of Tunis, the same with the dey of Algiers, is the prince or king of that kingdom.

BEZANS, cotton cloths, which come from Bengal; some are white, and others striped with several colours.

BEZANT, or **BESANT**. See the article **BESANT**.

BEZANTHER, the branch of a deer's horn, next below the brow-antler.

BEZOAR, in natural history and medicine, a general name for certain animal substances, formerly supposed to be effectual in preventing the fatal consequences of poison; but at present are very little valued, their boasted virtues being found to be merely chimerical.

BEZOARDIC, an appellation given to whatever partakes of the nature of bezoar; also to compound medicines whereof bezoar makes an ingredient.

BIA, in commerce, a name given by the Siamese to those small shells which are called cowries throughout almost all the other parts of the East-Indies. See the article **COWRIES**.

BIBLE, βιβλα, the book, a name given by Christians, by way of eminence, to a collection of the sacred writings, containing those of the Old and New Testament, and is justly looked upon as the foundation of the Jewish as well as the Christian religion. The Jews, it is true, acknowledge only the Scriptures of the Old Testament, the correcting and publishing of which is unanimously ascribed both by the Jews and Christians to Ezra. Some of the ancient fathers, on no other foundation than that fabulous and apocryphal book the second of Esdra, pretend that the Scriptures were entirely lost in the Babylonish captivity, and that Ezra had restored them again by divine revelations. What is certain is, that in the reign of Josiah, there were no other books of the law extant, besides that found in the temple by Hilkiah; from which original that pious king ordered copies to be immediately written out, and search made for all the parts of the Scriptures, by which means copies of

of the whole became pretty numerous among the people, who carried them with them into captivity. After the return of the Jews from the Babylonish captivity, Ezra got together as many copies as he could of the sacred writings, and out of them all prepared a correct edition, disposing the several books in their natural order, and settling the canon of the Scripture for his time, having published them, according to the opinion of most learned men, in the Chaldee character, as the Jews, upon their return from the captivity, brought with them the Chaldaic language, which from that time became their mother-tongue, and probably gave birth to the Chaldee translation of their Scriptures.

Chaldee BIBLE is only the glosses, or expositions made by the Jews when they spoke the Chaldee tongue; whence it is called *Targumim*, or paraphrases, as not being a strict version of the Scriptures.

Hebrew BIBLE. There is in the church of St. Dominic, in Bononia, a copy of the Hebrew Scriptures, which they pretend to be the original copy, written by Ezra himself. It is written in a fair character, upon a sort of leather, and made up into a roll, after the ancient manner: but its having the vowel points annexed, and the writing being fresh and fair, without any decay, these circumstances prove the novelty of the copy.

Greek BIBLE. It is a dispute among authors, whether there was a Greek version of the Old Testament more ancient than that of the seventy-two Jews employed by Ptolemy Philadelphus to translate that book: before Our Saviour's time, there was no other version of the Old Testament besides that which went under the name of the Septuagint. See *SEPTUAGINT*. But after the establishment of Christianity, some authors undertook new translations of the Bible, under pretence of making them more conformable to the Hebrew text. There have been about six of these versions, some whereof are charged with having corrupted several passages of the prophets relating to Jesus Christ; others have been thought too free in their versions, and others have been found fault with for having confined themselves too servilely to the letter.

Latin BIBLE. It is beyond dispute that the Latin churches had, even in the first ages, a translation of the Bible in their language, which being the vulgar language, and consequently understood by every body, occasioned a vast number of Latin versions. Among these there was one which was generally received, and called by St. Jerom the Vulgar or common translation. St. Austin gives this version the name of the Italic, and prefers it to all the rest. There were several other translations of the Bible into Latin, the most remarkable of which are the versions of St. Jerom, Santes

Pagninus, cardinal Cajetan, and Ifiodore Clarius, all from the Hebrew text.

Besides these translations by Catholic authors, there are some made by protestant translators of the Hebrew; the most eminent of their versions are those of Sebastian Munster, Leo Juda, Sebastian Castalio, Theodore Beza, &c.

Syrian BIBLE, a very ancient translation of the Scriptures into the Syriac language. Dr. Prideaux is of opinion that it was made in the first century after Christ; that the author of it was some Christian of the Jewish nation; and that it is the best translation of the Old Testament. This version is not always agreeable to the Hebrew text, but in some places more conformable to the Samaritan Pentateuch, and in others to the version of the Septuagint.

Arabic BIBLE. There are two sorts of Arabic versions of the Bible; the one performed by Christians, the other by Jews. Among the former there is one printed in the Polyglots of Paris and England, but both the author and the time it was written are unknown. Among all the Jewish performances of this kind, one only has been printed entire, which was done by Epenus, at Leyden, in the year 1622.

Ethiopic BIBLE. This version of the Old Testament was made immediately from the Greek text of the Septuagint; and there is a very plain agreement between this translation and the Alexandrine manuscript; the order of the chapters, the inscriptions of the Psalms, and every thing else being exactly similar. The Ethiopians attribute this version to Frumentius, the apostle of Ethiopia, sent thither by Athanasius, bishop of Alexandria.

Coptic, or Egyptian BIBLE, a translation of the Scriptures made immediately from the Greek of the Septuagint; and in which the Egyptian translator so religiously followed the Greek text, that he refused to make use of the labours of Origen and others, who had taken the pains to compare the Greek version with the Hebrew text. This version is doubtless very ancient, though neither the author, nor exact time of its being performed, are known.

Persian BIBLE. There are several versions of the Bible in the Persian language, most of which are in manuscript. Walton, in the London Polyglot, has published the gospels, translated by one Simon, the son of Joseph, a Christian of Persia, who lived about the middle of the fourteenth century.

Turkish BIBLE. There are several manuscript translations of the Bible in the Turkish language; and a version of the New Testament was printed at London in the year 1666.

Armenian BIBLE, a very ancient translation of the Scriptures into the Armenian language from the

crowned with two or more erect sharp awns. Botanists enumerate seven species of this plant, which are all natives of different parts of America.

BIDON, a liquid measure, containing about five pints of Paris, that is, about five quarts English, wine measure. It is seldom used but among ships crews.

BIGAMY, the possession of two wives at the same time. This is the interpretation of the word, in a law passed 1 Jac. I. which makes bigamy felony. Among the Romans, persons convicted of bigamy were branded with a note of infamy; and in France, they were anciently punished with death.

BIGAMY, in the canon law, is when a person either marries two women successively, or only marries one woman who had been married before; both which cases are accounted impediments to be a clerk, or to hold a bishopric. It is also bigamy when a person marries a woman who had been debauched before; or when he hath known his own wife after she has been debauched by another.

The Romanists make a kind of bigamy by interpretation; as when a person in holy orders, or that has made profession of some monastic order, marries. This the bishop can dispense with on some occasions.

Spiritual BIGAMY is when a person holds two incompatible benefices, as two bishoprics, two vicarages, &c.

BIGHT, in the marine, the double part of any rope, in contradistinction to the end; as, the bight of his cable has swept our anchor, that is, a part of the cable of another ship, in winding, has entangled itself under the claw or hook of our anchor. See **ANCHOR**.

BIGNONIA, the trumpet-flower, in botany, a plant having a rough stem, which sends out many weak trailing branches, which are furnished with winged leaves at every joint, placed opposite, and are composed of four pair of folioles, or small leaves, terminated by an odd one; these are serrated on their edges, and end in a long sharp point: the flowers, which are monopetalous and campanulated, are produced at the ends of the shoots of the same year in large bunches; these have swelling tubes shaped somewhat like a trumpet, from whence they had the appellation of trumpet-flower: they are of an orange colour, and appear the beginning of August; the fruit is a pod with two cells and two valves, containing several imbricated, compressed, winged seeds. This plant is propagated from seeds or cuttings.

BIGOT, a person foolishly obstinate, and perverely wedded to any opinion, but particularly an opinion of a religious nature.

BILANDER, in the marine, a small merchant vessel of two masts, having her main-yard and sail stretching from the middle of the deck to the stern,

parallel to her length, instead of hanging across, like those of other larger ships: the after, or hinder end of a bilander's main-yard is likewise pecked up, so as to form nearly an angle of forty-five degrees with the mast on which it is suspended.

Few vessels, however, are now equipped in this method, probably from the observation of its being attended with several inconveniencies.

BILE, **BILIS**, a yellow bitter liquor, separated from the blood in the liver, collected in the porous biliarious and gall-bladder, and thence discharged by the common duct into the duodenum.

The bile, when out of the body, is highly bitter, and the most acrid of all the animal fluids; it is neither of an alkaline nor an acid quality. It resists acceffence, and conveys the same quality to other substances with which it is mixed. It tends very much to putrefaction, which it promotes, when added to other substances disposed to it. It very soon mixes with water; and, when inspissated over a gentle fire, it dissolves, if exposed to the air. It does not burn in the fire, unless it be previously dried. It renders oil and oleaginous substances miscible with water. If it be rubbed with any tenacious substances, such as resins or gums, it resolves and attenuates them. It is coagulated by fire, alcohol of wine, acid spirits, and extract of galls. See *Boerhaave's Chym.* Vol. I. and his *Institut. Med.* Sect. 99.

From the preceding, and a great number of other experiments made on this fluid by Baglivi, Du Hamel, &c. it plainly appears, that the bile is a humour composed of an oil, a salt, and water. It may therefore be considered as a liquid animal sope, so that it is of an abstergent and resolvent quality. That it is so, the practice of some tradesmen is a sufficient proof; for dyers of cloth, in order to take out the grease which sticks to the wool, and hinders the adhesion of the colour, use sope, or putrid urine, after it has assumed an alkaline nature, or a lixivium of some fixed alkali: but they may, with equal success, use ox gall for the same intention. Painters also use the bile of animals for mixing and diluting their colours. It discovers its efficacy to be the same in medicines, where a saponeaceous quality is required, or where the intention is to absterge, where the sluggish vessels are to be stimulated, where a tenacious substance is to be resolved, or a viscid one attenuated. See *Boerb. Aph.* LXXV. 5.

BILGES, in naval architecture, those parts of the bottom of a ship, on either side, that approach nearer to an horizontal than a perpendicular direction, and on which the ship would rest if laid on the ground, or more particularly those parts on which she would rest only, exclusive of the keel which divides them.

BILGES are terminated in the ship's fore part by the lower part of the bow, and the hinder part by the

the buttock. See the articles *Bow*, *KEEL*, and *BUTTOCK*.

BILINGUIS, in a general use, implies a person who speaks two languages; but in law is used to signify a jury in a trial between an Englishman and a foreigner, when one half are natives, and the other strangers.

BILIOUS, something relating to the bile, or that partakes of its nature.

BILIOUS Fever. See *FEVER*.

BILL, in mechanics, a cutting instrument of iron, in the form of a crescent, used by husbandmen, gardeners, &c.

BILL, in trade, signifies an account of goods delivered to, or of work done for, a person.

BILL of Credit, an order given by a merchant or banker to a person, empowering him to receive money from his correspondents in foreign countries.

BILL of Entry, an account of goods entered at the custom-house, both inwards and outwards.

BILL of Exchange, a short order written on a slip of paper, by a merchant, &c. for paying to such a person, or his order, and in some countries to the bearer, in a distant place, a certain sum of money.

There are three things necessary to constitute a bill of exchange. 1. That it be drawn in one place upon some person in another. 2. That there be three persons concerned, the drawer, the presenter, or person in whose favour it is drawn, and the acceptor, or him on whom it is drawn. It must also mention that the value which the drawer has received, is either in bills of exchange, in money, merchandize, or other effects, which are to be expressed.

These bills are made payable either at sight, or so many days, weeks, or months after date; the space of a month being called *usance*, and two or three months after date, *double* or *treble usance*.

Bills of exchange are also either inland or foreign; the former is said to be only in the nature of a letter; but the latter is more regarded in law, because it is for the advantage of commerce with other countries, and consequently renders it an object of public concern.

Not only the drawer, but also every indorser of a bill is liable to the payment of it; for an indorser charges himself in the same manner, as if he had originally drawn the bill: and the plaintiff, in an action in such a case, is not obliged to prove the drawer's hand, because the indorser becomes a new drawer. He must however prove that he demanded the money of the drawer or drawers, or that he made enquiry, and could not find them in convenient time; for by the custom established among merchants, the indorser is to receive the money of the first drawer if he can; but if he cannot, the indorser must answer it.

The forging a bill of exchange, or any acceptance, is felony.

BILL of Lading, an acknowledgement signed by the master of the ship, and given to a merchant, &c. containing an account of the goods which the master has received on board from that merchant, &c. with a promise to deliver them at the intended place for a certain sum of money. Each bill of lading must be treble, one for the merchant who ships the goods, another to be sent to the person to whom they are consigned, and the third to remain in the hands of the master of the ship. It must however be observed, that a bill of lading is only used when the goods sent on board a ship are but part of the cargo; for when a merchant loads a vessel entirely on his own account, the deed passed between him and the master of the ship is called *charter-party*. See *CHARTER-PARTY*.

BILL of Parcels, an account given by the seller to the buyer, containing the particulars of all the sorts and pieces of the goods bought.

BILL of Sale is when a man, wanting a sum of money, delivers goods as a security to the lender, to whom he gives this bill, empowering him to sell the goods, in case the sum borrowed is not repaid with interest at the time appointed.

BILL of Store, a licence granted at the custom-house to merchants, by which they have liberty to carry duty-free, all such stores and provisions as the ship's crew may have occasion for during the voyage.

BILL of Suffrance, a licence granted to a merchant at the custom-house, suffering him to trade from one English port to another, without paying custom.

Bank BILL. See *BANK*.

BILL, in law, a security for money under the hand, and sometimes the seal of the debtor. It is of two sorts, a single bill without or with a penalty; the latter is the same as a bond, except its being without a condition.

BILL also implies a declaration in writing, expressing either some wrong the complainant has suffered from the defendant, or a fault committed by the person complained of against some law or statute.

This bill is sometimes exhibited to justices at the general assizes, by way of indictment, or referred to others having jurisdiction; but is more generally addressed to the lord chancellor. It contains the fact complained of, the damage sustained, and a petition or process against the defendant for redress; and is used both in criminal and civil cases. In the former, the words *billā vera* are indorsed by the grand jury upon a presentment, implying that they find the same founded on probable evidence, and therefore worthy of further consideration.

BILL in Parliament, signifies a paper containing propositions offered to the house to be passed by them,

them; and afterwards to be presented to the king, in order to receive the royal assent, and become a law.

BILL of *Attainder*, } See { **ATTAINDER.**
 BILL of *Appeal*, } { **APPEAL.**
 BILL of *Mortality*, } { **MORTALITY.**

BILLET, in heraldry, a bearing in form of a long square. They are supposed to represent pieces of cloth of gold or silver; but Guillim thinks they represent a letter sealed up; and other authors take them for bricks.

Billet implies that the escutcheon is all over strewed with billets, the number not ascertained.

BILLET-WOOD, small wood for fewel, cut three foot and four inches long, and seven inches and a half in compass; the affize of which is to be enquired of by justices.

BILLETING, in military affairs, is the quartering of soldiers in the houses of a town or village. Among fox-hunters, it signifies the ordure and dung of a fox.

BILLON, in the history of coins, a composition of precious and base metals, where the latter predominate: wherefore gold, under twelve carats fine, is called billon of gold; and silver, under six penny-weight, billon of silver. So little attention was paid formerly to the purity of gold and silver, that the term billon of gold was applied only to that which was under twenty-one carats; and billon of silver to that which was lower than ten penny-weight.

BIMEDIAL. If two medial lines AB and BC (Plate XVIII. fig. 11.) commenfurable in power, only, are compounded, and contain a rational rectangle, the whole line AC is irrational, and called a first bimedral line. *Barrow's Euclid. Lib. X. Prop. 38.*

BINARY ARITHMETIC, that wherein unity or 1 and 0 are only used.

This was the invention of Mr. Leibnitz, who shews it to be very expeditious in discovering the properties of numbers, and in constructing tables: and Mr. Dangeourt, in the History of the Royal Academy of Sciences, gives a specimen of it concerning arithmetical progressions; where he shews that, because in binary arithmetic only two characters are used, therefore the laws of progression may be more easily discovered by it than by common arithmetic.

The author, however, does not recommend this method for common use, because of the great number of figures required to express a number.

BINARY MEASURE, in music, is a measure which is beaten equally, or where the time of rising is equal to that of falling; usually called common time.

BIND-WEED, *Convolvulus*, in botany; see CONVOLVULUS.

BING, in the alum works, denotes a heap of alum thrown together in order to drain.

BINNACLE, in the marine, a wooden case or box standing upon the quarter-deck, immediately before the helm, or steering-wheel, containing three little apartments, viz. one in the middle for a light, and those on each side for the sea-compasses which direct the ship's course: the middle division has a glass on each side, whereby to throw a light upon the compass, that the man at the helm may observe it in the darkest weather. There are always two binnacles on the deck of a ship of war; one being designed for the man who steers, and the other for the officer who superintends the steering, which is called conning. See COMPASS, and QUARTER-MASTER.

BINOCULAR Telescope. See TELESCOPE.

BINOMIAL Root, in algebra, is a root consisting of two members connected with the sign +, or -; thus $1+x$, or $1-x$ are binomials consisting of the sums and differences of these quantities. See *Binomial Root*.

BIOGRAPHY, a very instructive species of history, containing the lives of remarkable persons.

The word is formed from the Greek $\beta\iota\omicron\varsigma$, life, and $\gamma\rho\alpha\phi\omicron$, to describe.

BIOUAC, in military affairs, a night-guard performed by the whole army, when there is any apprehension of danger from the enemy.

BIQUADRATIC, the fourth power of any number or quantity.

BIQUADRATIC Equation, in algebra, is an equation where the unknown quantity has four dimensions; thus, $x^4+pa^2x^2+paax^2+pa^2x+a^4=0$, is a biquadratic equation, because the unknown term x , is of four dimensions. See *Biquadratic EQUATION*.

BIQUINTILE, an aspect of the planets when they are 144 degrees distant from each other.

BIRCH-TREE, *Betula*, in botany, a genus of amentaceous plants. The common birch grows in several woods in England; it is tall, and produces many flexible branches. The outer bark of the trunk is thick, rough, whitish, and full of clefts; that which lies next is smooth and transparent: the wood is white, and the boughs are so tough and flexible, that they are much used for making hoops for casks, and their twigs are commonly employed for making brooms. The leaves are somewhat oval, serrated, and of a deep green. The flowers are male and female, and produced on catkins, which are about an inch and a half long, consisting of many reddish florets, disposed like scales; in the female flower the calyx is lightly divided into three segments. The fruit is a cylindric cone,

cone, having seeds which are oval, winged, and included in the scales of the katkin.

This tree is propagated by suckers or young plants, from the woods where they naturally grow; but in places where there are no young plants near, they may be raised from seeds, which should be carefully gathered when the scales begin to open, which is in autumn, and is the proper season for sowing, observing to chuse a shady situation, where the plants will thrive much better than if exposed to the full sun. Birch being much esteemed for its wood, may be cultivated upon barren lands; where better trees will not thrive; for there is no ground so bad but this tree will thrive in it; it will grow in moist springy land, or in dry gravel or sand, where there is little surface. These may be transplanted any time from the middle of October till the middle of March, when the ground is not frozen. In dry land the autumn is the best season, but where it is moist, the spring is to be preferred: the distance they should be planted is six feet square, that they may soon cover the ground, and by standing close they will draw each other up, and thrive the better where they are much exposed. When young trees have been planted two years, they should (if designed for underwood) be cut down within six inches of the surface, which will cause them to shoot out strong and vigorous branches; but if they are designed for large trees, it will be better to let them stand three years before they are headed down, which should be done within three inches of the ground, that their stems may be straight and handsome, observing when they put out, whether they produce more than one shoot, which if they do, they must all be cut off, except the strongest and most convenient shoot, which must be trained up for a stem.

The timber of birch, though accounted the worst of all others, yet is not without its various uses: besides its service for hoops and brooms, it is used for ox-yokes, in chair-making, dishes, bowls, ladles, and for divers other purposes. In Russia and Poland they cover their houses with the bark of the birch-tree, instead of slate or tile.

In some places these trees are tapped in the spring, and the sap drawn out to make birch-wine, which is done in the following manner: In the middle of March, cut an oblique hole, or rather a slit, under the branch of a well spreading birch-tree, which keep open by a small wedge of wood, or stone put therein: to this hole or slit fix a bottle, to receive that clear water or sap as will distil itself out of the aperture into the bottle, which must be taken away when full, and others fixed in its place. It is said, that one tree will bleed a gallon or two in a day. Having in this manner obtained a sufficient quantity of the sap or birch-water, put to every gallon thereof a quart of honey, well stirred

up together, and boil it almost an hour with a few cloves, and a little lemon-peel, keeping it well scummed. When it is sufficiently boiled, and after become cold, put to it two or three spoonfuls of good ale-yeast, which will cause it to work like beer: when the yeast begins to settle, bottle it up, as is done by other liquors, and in a competent time it will become a most brisk and spirituous wine, and a very great opener. If honey should be disagreeable, instead thereof use a pound of the best double-refined sugar; or it may be dulcified with the best Malaga raisins, which last will make it an exceeding fine wine. This wine is very good for the phthisic, dissolves the stone in the bladder, and greatly sharpens the appetite, being drank before eating.

The leaves and bark of the birch-tree have been employed chiefly externally, as resolvents, detergents, and antiseptics. With regard to the leaves, they discover to the touch a resinous unctuousity, and to the taste an unpleasant bitterness: being rubbed a little, they yield a pretty strong, and not disagreeable smell. The bark has been recommended in fumigations for correcting contagious air; the membranes are highly inflammable, in burning yield no particular smell, and give out a resinous exudation without smell or taste; the brittle part is less inflammable; it emits a strong acid vapour without resin.

There are three other species of birch, one of which is a native of the Alps, and the northern parts of France; and the others of North America, where the Indians make canoes of their bark, which are very light, and of long duration.

BIRD, *Avis*, in zoology, one of the six general classes of animals, the characters of which are, that their body is covered with feathers, and that they have two wings, two legs, and a bill of a horny substance; the females likewise are all oviparous.

The knowledge of birds, of the orders and genera into which they are subdivided, and of their natures, uses, figures, &c. constitutes a particular science, under the name of ornithology. See **ORNITHOLOGY**.

BIRD-LIME, a viscid substance, prepared after different ways. The most common bird-lime among us is made from holly-bark, boiled ten or twelve hours; when the green coat being separated from the bark, it is covered up a fortnight in a moist place, then pounded into a tough paste, so that no fibres of the wood are discernible, and washed in a running stream till no motes appear, put up to ferment four or five days, skimmed as often as any thing arises, and laid up for use. To use it, a third part of nut-oil, or thin grease, must be incorporated with it over the fire.

BIRD'S-FOOT, in botany; see **ORNITHOPUS**.

BIRTH,

BIRTH, *Partus*, in midwifery, signifies the same with delivery. See the article **DELIVERY**.

An immature birth, or that which happens before the usual time of pregnancy is completed, is otherwise called an abortion. See the article **ABORTION**.

For the proportion of births to marriages, burials, &c. see the articles **MARRIAGES**, **BURIAL**, &c.

After-BIRTH. See **AFTER-BIRTH**.

BIRTH, in the marine, the station in which a ship rides at anchor, either alone, or in a fleet or squadron; or the distance between a ship and any adjacent object; as she lies in a good birth, *i.e.* is moored in a convenient situation, or at a proper distance from the shore, and other vessels.

Birth also signifies the room or apartment where any particular number of the officers or crew eat and sleep: in a ship of war, there is commonly one of these between every two guns.

BIRTHWORT, in botany; see **ARISTOLOGIA**.

BIS, in botany, a name given by the ancients to two different genera of plants, now called monkhood and hemlock.

BIS ANNUAL, an appellation given to such plants as do not flower till the second year.

BISCUTELLA, buckler-mustard, in botany, a genus of plants producing cruciform flowers, each consisting of four obtuse petals: in the center is placed an orbicular compressed germin, supporting a single prement style; it hath six stamina, two of which are shorter than the rest; the fruit is a compressed bilocular erect capsule, containing a single compressed seed. This genus was called by Tournefort *thlaspidium*, and are natives of several parts in the south of Europe.

BISERRULA, in botany, an annual plant, which grows naturally in Italy, Sicily, Spain, and the south of France; it sends forth many angular stalks, which trail on the ground, and are subdivided into many branches, which are furnished with long winged leaves, composed of many pairs of lobes, and terminated by an odd one: these are heart-shaped. Toward the upper part of the branches comes out the pedicle, which sustains several papilionaceous flowers, of a purple colour, collected together; which are succeeded by plain pods about an inch long, indented on both sides, and divided in the middle by a longitudinal nerve, containing two rows of kidney-shaped seeds.

This plant was called by Tournefort *pelecinus*.

BISHOP, a prelate, or person consecrated for the spiritual government of a diocese.

A bishop is the highest ecclesiastical dignitary, the chief officer in the hierarchy or œconomy of church government. The apostles, after our Saviour's ascension, went forth preaching the gos-

pel in the particular provinces allotted to them, and appointed the first converts of every place through which they passed, or, as Clemens Romanus expresses it, "the first fruits of their ministry," to be the bishops and deacons of the churches planted by them. Thus Tertullian says, Clemens was ordained bishop of Rome by St. Peter, and Polycarp bishop of Smyrna, by St. John.

The earliest account we have of British bishops is carried up no higher than the council of Arles, assembled by the emperor Constantine, in the fourth century; at which were present the bishops of London, York, and Caerleon.

Upon the vacancy of a bishop's see, the king grants a licence, or *conge d'eslire*, under the great seal, to the dean and chapter, to elect the person whom by his letters missive he hath appointed; and they are to choose no other. The dean and chapter having made their election accordingly, certify it under their common seal to the king, and to the archbishop of the province, and to the bishop thus elected: then the king gives his royal assent, under the great seal, directed to the archbishop, commanding him to confirm and consecrate the bishop thus elected. The archbishop then subscribes his *fiat confirmatio*, and grants a commission to the vicar-general to perform all the acts requisite thereto: who thereupon issues out a summons to all persons who may object to the election, to appear, &c. which citation is affixed on the door of Bow-church. At the time and place appointed, the proctor for the dean and chapter exhibits the royal assent, and the commission of the archbishop, which are both read, and accepted by the vicar-general. Then the new bishop is presented by the proctor of the vicar-general; and three proclamations being made for the opposers of the election to appear, and none appearing, the vicar-general confirms and ratifies the choice of the person elected; who takes the oaths of supremacy, canonical obedience, and that against simony.

Till this act of confirmation is performed, the bishop elect may be rejected, because there may be reasons assigned why he should not be made a bishop; which is the reason of the above-mentioned citations and proclamations.

A bishop of England is a peer of the realm, and, as such, sits and votes in the house of lords. He is a baron in a threefold manner, viz. feudal, in regard of the temporalities annexed to his bishopric; by writ, as being summoned by writ to parliament; and by patent and creation. Accordingly he has the precedence of all other barons, and votes both as baron and bishop.

BISHOP'S-COURT, an ecclesiastical court, held in the cathedral of each diocese by the bishop's chancellor, who judges by the civil and canon law; and

and if the diocese be large, he has commissaries in remote parts, who hold what they call consistory courts, for matters limited to them by their commission.

BISHOP'S-REED, in botany. See **AMMI**.

BISHOPING, a term among horse-dealers, to denote the several artifices used by them on an old or bad horse, to conceal his natural defects, and impose upon the buyer.

BISHOPRIC, a diocese, or the district over which a bishop's jurisdiction extends.

BISKET, or **BISCUIT**, a general name for the bread used in the sea-service, especially in long voyages.

Bisket, in order to be good, should be made six months before it is put on board a ship; it should also be made of good wheat flour, thoroughly cleaned from the bran.

Manner of making Sea-Biscuit. The flour is first wet in the kneading-trough, with a sufficient quantity of water, and covered for some time with a cloth. It is then well kneaded with a brake, and the dough divided into pieces of about three ounces each. These pieces are again kneaded singly, and laid in rows, and the baker, after shaking some flour over them, lays another row upon the former; and continues kneading and placing his pieces of dough upon the last pieces, till the whole batch, or quantity baked at once, is finished: the pieces of dough are then flatted into cakes, pricked with an instrument for that purpose, and placed regularly in the oven, where they stand about half an hour, when they are taken out of the oven, and carried to the store-room.

The oven is sufficiently heated while the dough is kneading and forming into cakes, so that there is no loss of time during the whole day. Five persons are sufficient for two ovens, two of which are the master-bakers, which have each a mate, the fifth person being called the idle-man. The master-bakers assist in kneading the dough, and flattening it into cakes, and setting the biskets in the ovens. The mates also assist in kneading the dough, flattening it into cakes, heating the oven, and tossing the cakes into it. The last operation they perform with great dexterity, the master-baker constantly catching the cake on his peel, and placing it regularly in the oven. The idle-man fetches in the wood, wets and kneads the flour in the kneading-trough, takes it thence, and kneads it with the brake, carries it into the bake-house, pricks the cakes, and carries them to a small table placed at the oven's mouth, whence the mate takes them, and tosses them into the oven.

BISKET, among confectioners, signifies a kind of bread made of fine flour, eggs and sugar, with the addition of rose or orange-flower-water. Sometimes aniseeds, carraway-seeds, preserved orange, citron, or lemon-peel, are added, and the different

compositions distinguished by different names, as feed-bisket, long-bisket, round-bisket, Naples-bisket, sponge-bisket, &c.

BISMUTH, or **TIN-GLASS**, in natural history, a sparkling white semi-metal, very ponderous, considerably hard and sonorous, extremely brittle, without any degree of malleability, falling in pieces under the hammer, and reducible by triture into fine powder. When broke, the surface of the fracture appears composed of bright plates or flakes, larger than those of the other semi-metals. In its external appearance, it has a great resemblance to regulus of antimony and zinc, differing little otherwise than in the largeness of the plates, and in its contracting a yellowish cast on the surface exposed to the air. In its intrinsic properties, it is extremely different; melting far more easily, not evaporating so readily, being differently acted upon by acids, producing different effects upon other metallic bodies, &c.

BISNOW, or **BISCHNOU**, a sect of the Bani-ans in the East-Indies, who live wholly on herbs, pulse, butter, and milk. They sing hymns in honour of their god, whom they call Ram-ram, and mix their devotions with dances and the sounds of musical instruments.

BISSECTION, in geometry, the dividing a line, angle, &c. into two equal parts.

BISSEXTILE, in chronology, a year consisting of 366 days, being the same with our leap-year; likewise the day which is this year added, is called bissextile. The mean tropical year, or that mean space of time wherein the sun or earth, after departing from any point of the ecliptic, returns to the same again, consists, according to Dr. Halley's tables, of 365 days, 5 hours, 48 minutes, 55 seconds: but the year made use of by the ancient Egyptians consisted only of 365 days, which being 5 hours, 48 minutes, 55 seconds too little, they lost a day nearly every four years. Julius Cæsar, when high-priest among the Romans, observing the inconvenience, ordered that every fourth year should have an additional or intercalary day, and the year when it happened was called bissextile; but this method of computation (which is called the Julian, or Old Stile,) is erroneous; for the equinoxes and solstices anticipate or come earlier than the Julian account supposes them to do by 11' 5" in each mean Julian year, or 44 minutes, 20 seconds in every four years, or 3 days, 1 hour, 53 minutes, and 20 seconds, in every four hundred Julian years.

In order to correct this error in the Julian year, the authors of the Gregorian method of regulating the year, when they reformed the calendar in the beginning of October 1582, directed that three intercalary days should be omitted or dropped every four hundred years, by reckoning all those years whose dates consist of a number of intire hundreds

not divisible by 4, such as 1700, 1800, 1900, 2100, &c. to be only common and not bissextile, or leap years, as they would otherwise have been, and consequently omitting the intercalary days, which, according to the Julian account, should have been inserted in the month of February in those years; but, at the same time, they ordered, that every fourth hundredth year consisting of a number of intire hundreds divisible by 4, such as 1600, 2000, 2400, 2800, &c. should still be considered as bissextile or leap years; and consequently, that one day should be intercalated as usual in those years.

This correction, however, did not intirely remove the error, for the equinoxes and solstices still anticipate $1^h 53' 26''$ every four hundred Gregorian years; but that difference is so inconsiderable as not to amount to twenty-four hours, or to one whole day, in less than 5082 Gregorian years.

Pope Gregory XIII. in the year 1582, finding that the equinox had anticipated, from the above reasons, since the council of Nice held in the year 325, ten whole days, ordered that these ten days should that year be taken out of the calendar, and that the 11th of March should be called the 21st, and this method of computation was immediately followed by most foreign countries. Great Britain, however, still followed the old or Julian stile till the year 1752, during which interval one day more was anticipated. It was therefore ordered by act of parliament, that eleven days should that year be taken out of the calendar, and that the natural day following the second of September, should be called the fourteenth, omitting the intermediate eleven days, and that the new stile should for the future be observed. By this correction, the feasts and fasts of the church are now kept according to the original decision of the Nicene council.

BISTER, or rather BISTRE. See BISTRE.

BISTORTA, bistort, or snakeweed, in botany, a genus of octandrious plants. The common great bistort has a thick, oblong, jointed root, about the thickness of the finger, surrounded with bushy fibres; it is of a blackish brown colour without, and reddish within: the leaves are oblong, broad, and acuminate like the dock, but less; they are full of veins, and of a dark green colour above, and bluish underneath, standing on long pedicles, and forming a narrow margin on each side: among these arise round, slender, jointed, unbranched stalks, beset with a few smaller and narrower leaves, which have no pedicles, bearing on the top spikes of a petalous flower, consisting of a turbinated cup divided into five segments; the pistil turns to a triangular acute seed of a shining black, contained in the calyx. The root of this plant is only in use, and is said to be balsamic, vulnerary, and astringent, and therefore used against all kinds of fluxes, particularly in hemorrhages, spitting of

blood, and vomiting; it has been sometimes given in intermitting fevers, and sometimes also in small doses as a corroborant and antiseptic in acute and malignant fevers; the common dose of bistort root is from fifteen to twenty grains, and, in urgent cases, it is extended to a dram. This genus is classed by Dr. Linneus with the polygonum. It flowers in May, and produces new spikes until August, and grows well in divers parts of England.

BISTOURY, in surgery, an instrument for making incisions, of which there are different kinds, some being of the form of a lancet, others straight and fixed in the handle like a knife, and others crooked with the sharp edge on the inside.

BISTRE, among painters, signifies the burnt oil extracted from the foot of wood.

It is of a brown transparent colour, having much the same effect in water-painting, where alone it is used, as brown pink in oil. Though this colour is extremely serviceable in water-colours, and much valued by those who know and can procure it, yet it is not in general use here, perhaps on account of its not being easily procured of a perfect kind; hardly any of it being good, except that imported from France. Perhaps the principal reason for this is, that dry beech-wood affords the best foot for making it; and it is not easy to procure such here without mixture of the foot of green wood, or other combustibles that deprave it for this purpose; or it is possible that they who have pretended to prepare it, have been ignorant of the proper means; there not being any recipe or directions in books that treat of these matters, from whence they could learn the proper process.

Bistre may, however, be prepared with great ease in the following manner.

Take any quantity of foot of dry wood, but let it be of beech where-ever that can be procured. Put it into water in the proportion of two pounds to a gallon; and boil them half an hour: then, after the fluid has stood some little time to settle, but while yet hot, pour off the clearer part from the earthy sediment at the bottom; and if on standing longer it forms another earthy sediment, repeat the same method; but this should be done only while the fluid remains hot: evaporate then the fluid to dryness; and what remains will be good bistre, if the foot was of a proper kind.

The goodness of bistre may be perceived by its warm deep brown colour, and transparency when moistened with water.

BIT, or BITT, an essential part of a bridle. Its kinds are various: 1. The mustel, snaffle, or watering-bit. 2. The canon-mouth, jointed in the middle. 3. The canon with a fast mouth, all of a piece, only kneed in the middle, to form a liberty or space for the tongue; fit for horses too sensible, or ticklish, and liable to be continually bear-

bearing on the hand. 4. The canon-mouth, with the liberty in form of a pigeon's neck; proper where a horse has too large a tongue. 5. The canon with a port mouth, and an uplet or mounting liberty; used where a horse has a good mouth but large tongue. 6. The scatch-mouth, with an uplet; ruder but more secure than a canon-mouth. 7. The canon-mouth with a liberty; proper for a horse with a large tongue, and round bars. 8. The masticadour, or flavering bit, &c. The several parts of a snaffle, or curb-bit, are the mouth-piece, the cheeks and eyes, guard of the cheek, head of the cheeks, the port, the welts, the campanel or curb and hook, the bolsters, the bolsters and rabbits, the water-chains, the side-bolts, bolts and rings, kirbles of the bit or curb, trench, topol, flap, and jeive.

Bit also denotes the iron part of a piercer, auger, and the like instruments.

Bit of a Key, the part which contains the wards. See **WARDS**.

Bits, in naval architecture, strong pieces of square timber let down through, and fixed in holes of, the decks above and below, called mortises, and bolted to the beams. There are several bits in a ship, the principal of which are those for the cable, whose upper parts commonly reach about three or four feet above the deck, over which the cable passes: they are supported on the forepart by strong knees bolted to the deck, and fortified by a cross-piece of equal thickness with themselves, which is bolted and forelocked to the bits. The ends of the cross-piece reach about two or three feet beyond the bits, and is fixed about two feet below their upper-ends; around these the cable is gradually veered away, without which it would almost be impossible to prevent it from running out to the end when the ship rides a great strain, which is always the case in a storm or in a rapid tide. In ships of war there are commonly two pair of cable bits; and when they are both used at once, the cable is said to be double-bitted. See *Freshen the Hawse*, **SERVICE**.

To bit the cable is to put the double part or bight of it round the bits. The other bits are of a smaller kind for fastening the topfall sheets. See **QUARTER-BLOCK**.

BITTER, *Amarus*, an epithet given to all bodies of an opposite taste to sweetness.

Bitters are accounted stomachic and cleansing, and are said to resist putrefaction, correct acidities, and assist digestion; though there are not wanting some who will have them to be hurtful to the stomach, except in so far as their astringency contributes to brace the fibres.

BITTER-APPLE, in botany. See **COLOCYNTHIS**.

BITTER-SWEET, in botany. See **SOLANUM**.

BITTER-VETCH, in botany. See **ARBUS**.

BITTERN, in ornithology, the name of a bird of the heron kind, called by authors, *ardea fletularis*; and by some *taurus*, *botaurus*, *butorius*, and *ocnus*. In English, the butter-bump, and mire-drum. It is nearly of the size of a common heron; its head is small and narrow; its crown is black; and there is also a black spot on each side, near the angle of the mouth. Its throat and sides are reddish, variegated with black transverse lines; the neck is covered with very long feathers, which make it appear much thicker and shorter than it really is; its belly is of a dusky white, with a cast of brownish red, and its back is variegated with a pale reddish brown and black. It makes a very remarkable noise, which it repeats either three or five times. It is heard only in the building-time, which begins in February. The common people, from the singularity of the noise, think the bird, in order to make it, sticks its beak in a reed, or in the mud. It is commonly found in sedge and reedy places, near the waters, and sometimes in hedges. Towards autumn this bird flies very high in an evening after sun-set, rising with a spiral ascent, till quite out of sight; and as they rise, they make an odd noise, not at all like their usual note. This they repeat also very often, as they are on the wing in the night; and hence they are called by some, though improperly, the night-raven. It builds on the ground, and lays five or six eggs, which are roundish, and of a greenish white. When wounded, and going to be taken, it strikes at the person's eye, and ought therefore to be carefully guarded against.

BITTERN, in the salt-works, a liquor left after the boiling and crystallizing of the salt, of a nauseous bitter taste. It remains in the pans after the boiling is finished, and is thence conveyed to a pit without the works, and at proper seasons, with a small addition of oil and vitriol, boiled into what is improperly called *Epsom salt*. The factitious salt mirabile is made at the salt works from the salt that shoots spontaneously from the bittern.

BIVALVULAR, or **BIVALVE**, in botany, an appellation given to such pods or capsules as consist of two valves inclosing the seeds.

BIXA, in botany, a shrub which grows naturally in the warm parts of America, where it rises with an upright stem to the height of eight or ten feet, sending out many branches at the top, forming a regular head: these are furnished with heart-shaped leaves ending in a point, which have long footstalks. The flowers are produced in loose pannicles at the end of the branches; these are of a pale peach colour, having a double series of petals, each series consisting of five, with a great number of bristly stamina, which are about half the length of the same colour: when the flower is decayed, the germen becomes an oval heart-shaped capsule, a little

little compressed, covered with bristles, formed of two valves, opening at the angles, with only one cell with an interior bivalve membrane. The seeds are numerous and turbinated, covered with a red pulp or paste, which colours the hands of those who touch it, and is collected for the use of dyers and painters, by steeping the seeds in hot water, and with the hands washed until the seeds are clean; then after pouring away the water they leave the sediment to harden, and make it up in balls, which are sent to Europe: it is also used by the Americans to dye their chocolate; and the natives used to paint their bodies with it when they went to the wars. This plant is propagated by its seeds, but being tender it requires a hothouse in this climate.

BLACK, a well known colour, supposed to be owing to the absence of light; all the rays thereof being imbibed by the black bodies. See COLOUR and LIGHT.

Black bodies are not only warmer, but more inflammable than others, as is proved by various experiments; for which the curious may consult Boyle, 'S Gravefande, and other philosophers who have treated of this subject.

BLACK, among dyers, one of the five simple and mother colours used in dying. It is made differently, according to the several qualities of the stuffs that are to be dyed. For stuffs of a high price, as woollen cloth, an ell and a half, or an ell and a quarter wide, broad and narrow ratteens, fine woollen druggets, &c. they must use a black made of the best woad and indigo, inclining to a bluish brown. The goodness of the composition consists in there being not above six pounds of indigo ready prepared to each ball of woad, when the latter being in the tub, begins to cast its blue flower; and in not being heated for use above twice; after which it must be boiled with alum, tartar, or ashes of lees of wine; then maddered with common madder; and lastly, the black must be given with gall-nuts of Aleppo, copperas, and sumach. As for more indifferent stuffs, such as small ratteens and shalloons, as they cannot pay for the expence of maddering, it is sufficient that they be well boiled with woad, and afterwards blacked with gall and copperas. There is likewise the Jesuit's black, which is made with the same ingredients as the good black, but without having first dyed the stuff blue.

German BLACK, called by some Frankfort black, is made with the lees of wine, burnt, washed afterwards in water, then ground in mills made for that purpose, with ivory, bones, or peach-stones, also burnt. It comes from Frankfort, Mentz, and Straßbourg, either in lumps or powder, and must be shofen moist, without having been wetted, of a fine shining black, soft, friable, light, and with as few shining grains as possible.

Bone-BLACK is made with the bones of oxen,

cows, &c. and is used in painting; but is not so much esteemed as ivory-black.

Hart's BLACK, that which remains in the retort after the spirits, volatile salt, and oil, have been extracted from hart's-horn. It answers the purposes of painters almost as well as ivory-black.

Spanish BLACK is nothing but burnt cork; it is used in several works. It should be light, and have as few grains of sand mixed with it as possible.

Earth-BLACK, a sort of coals found in the ground, which the painters and limners use to paint in fresco, after it has been well ground.

There is also a black made with gall-nuts, copperas, or vitriol, such as common ink: and a black made with silver and lead, which serves to fill up the cavities of engraved things.

Lamp-BLACK is the foot of oil collected as it is formed by burning. It is a brownish black; but nevertheless, being of a good texture for mixing either with oil or water, and drying well with oil, it is the principal black at present used in all nicer kinds of painting: for notwithstanding ivory-black far surpasses this in colour, the gross and adulterate preparation of all that is to be now obtained has occasioned it to be greatly rejected.

The lamp-black is made by burning oil in a number of large lamps in a confined place, from whence no part of the fumes can escape; and where the foot formed by these fumes, being collected against the top and sides of the room, may be swept together and collected: and this being put into small barrels, is sold for use without any other preparation.

The goodness of lamp-black lies in the fullness of the colour, and the being free from dust or other impurities. The lightness of the substance furnishes the means of discovering any adulteration if to a great degree; as the bodies with which lamp-black is subject to be sophisticated are all heavier in a considerable proportion.

Ivory-BLACK is the coal of ivory or bone, formed by giving them a great heat, all access of air to them being excluded. It is, when pure and genuinely prepared from the ivory, a full clear black; and would be the most useful of any, in any kind of painting, but that it is apt to dry somewhat too slowly in oil. At present, nevertheless, being prepared only by those who manufacture it from bones in very large quantities for coarse uses, and sell it at an extreme low price, it is so grossly levigated, being ground only in hand or horse-mills, and adulterated moreover copiously with charcoal dust, which renders it of a blue cast, that it is wholly exploded from all more delicate purposes, and lamp-black used in the place of it, though inferior, with regard to the purity and clearness of the black colour, to this when good. As the ivory-black, notwithstanding, has its merit in most kinds of painting,

painting, when its preparation is properly managed, particularly in water and varnish; those who desire to have it may prepare it themselves in perfection by the following means.

Take plates, chips, or shavings of ivory, and soak them in hot linseed oil; or if filings are to be more easily procured, they may be used moistened with the hot oil: put them into a vessel which will bear the fire, covering them with a fort of lid made of clay and sand, which should be dried, and the cracks repaired before the vessel be put into the fire. Procure this vessel to be placed in a tobacco-pipe maker's or potter's furnace, or any such fire; and let it remain there during one of their heats. When it shall be taken out, the ivory will be burnt properly; and must be afterwards thoroughly well levigated on the stone with water; or it should, indeed, to have it perfectly good, be also washed over.

Those who have a calcining furnace, may very commodiously burn the ivory in it; and the fire need not be continued longer than while the fumes, that arise from the vessel containing the ivory, appear to flame. This operation may likewise be performed in a subliming furnace, by putting the ivory in a retort, coated with the fire-lute, and fixing the retort for the sublimer; and a proper receiver being fitted to the receivers, the fumes will be detained in it, and the smell prevented from being in the least troublesome: the fire must in this case be continued while any gross fumes come over.

The goodness of ivory-black may be perceived by its full black colour, not inclining too much to blue; and by its fineness as a powder.

Blue-Black is the coal of some kind of wood, or other vegetable matter, burnt in a close heat where the air can have no access. The best kind is said to be made of vine stalks and tendrils: but there are doubtless many other kinds of vegetable substances from which it may be equally prepared. It is, when good, a fine bluish black colour, useful in most kinds of paintings for many purposes; but is rarely to be had at present well prepared; and, therefore, much neglected in most nicer cases.

Those who desire to have blue-black perfectly good, may prepare it in the manner above directed for the ivory-black, from the vine stalks or tendrils, or any other twigs of wood of an acid taste and tough texture; but the soaking in oil, prescribed for the ivory, must be here omitted.

The goodness of the blue-black consists in the cleanness and blue cast of its black colour; and the perfectness of its levigation, which should be managed as directed for the ivory-black.

Carrier's Black signifies a teint or dye laid on tanned leather; of which there are usually two, the first made of galls, four ale, and old iron; the second of galls, copperas, and gum-arabic.

BLACK-BIRD, *Merula*, in ornithology. See the article **MERULA**.

BLACK Land, in agriculture, a term by which the husbandmen denote a particular sort of clayey soil, which, however, they know more by its other properties than by its colour, which is rarely any thing like a true black, and often but a pale grey. This, however pale when dry, always blackens by means of rain; and when plowed up at those seasons, it sticks to the plow-shares; and the more it is wrought, the muddier and dufkier-coloured it appears. This sort of soil always contains a large quantity of sand, and usually a great number of small white flones.

BLACK Flux, in minerology, a flux used in the assaying of ores, and is made as follows:—Take one part of nitre, and two parts of common tartary; reduce each to powder, mix them together, and deflagrate the whole in a crucible, by lighting the mixture at the top; which thus turns to a kind of alkaline coal, that is to be pulverized and kept in a close glass, to prevent its dissolving, as it would do in a moist air.

This flux is of general use; and to have it ready at hand, shortens the business of making assays in metallurgy, and renders the operation more exact than when crude tartar and nitre are employed; because the deflagration might thus carry off some part of the ore, and defraud the account: for the same reason the mixture is here directed to be fired at top, otherwise a considerable part might be lost in the deflagration, which would prove much more tumultuous and violent, if the matter was thrown into a red-hot crucible. *Shaw's Chem. Lectures.*

BLACK Tin, in minerology, a denomination given to the tin-ore when dressed, stamped, and washed ready for the melting-houses, where it is refined into a pure metal.

It is prepared into this state by means of beating and washing; and when it has passed through several baddles or washing-troughs, it is taken up in the form of a black powder like fine sand, called black-tin.

BLACK, in heraldry, is called sable. See the article **SABLE**.

BLACK, in horsemanship. Black horses are very beautiful, especially when they are of a jet shining black, and well marked, and have not too much white: for as a great deal of white, especially when it spreads round their eyes, and a great way up their legs, adds nothing to their beauty, so neither does it add any thing to their goodness. The English black horses have more white than the black horses of any other country. I have known many fine Spanish horses, some Arabs, and one Egyptian, the only one I ever saw of that country, all without any white; and the Dutch and Danish horses seldom have much; though a star of blaze, and sometimes a white muzzle, and one or more of the feet tipped with white, always looks beautiful and lively, and is no diminution to the

goodness of a horse, but most think an addition, from an opinion that horses without any mark are generally stubborn and ill-conditioned. Some black horses have brown muzzles, are brownish on their flanks and between their hips: these are often called black browns, as they are not a perfect black, but approach near to the colour of a tawny black hound: some are of a lighter colour about their muzzles, and are called mealy-mouthed horses; and of this sort are the pigeon-eyed horses, which have a white circle round their eye-lids, and their fundaments often white. But after all, I have found many of the English black horses, especially of the largest breed, not so hardy as the bays and chefnuts, &c. Those that partake most of the brown, are generally the strongest in constitution. *Gibson on Horses.*

BLACK-BERRY, in botany. See RUBUS.

BLACK-BOOK of the Exchequer. See the article EXCHEQUER.

BLACK-STRAKES, in the marine, those planks which are situated immediately above the bends of a ship (see the article BENDS): they are always covered with tar and a mixture of lamp-black, and form a beautiful variety with the white bottom below, and the scraped planks, covered with turpentine, or varnish of pine, above.

BLACKNESS, the quality of a black body, or a colour arising from such a texture and situation of the superficial parts of the body, as does deaden, or rather absorb the light falling on it, without reflecting any, or very little to the eye. Sir Isaac Newton in his Optics shews, that for the production of black colours, the corpuscles must be less than those which exhibit any other colours; because where the sizes of the component particles are greater, there is too much light reflected, to constitute this colour: but if there be a little less than is requisite to reflect the white, and very faint blue of the first order, they will reflect so little light as to appear intensely black, and yet may perhaps reflect it variously to and fro within them so long till it happen to be sifted and lost; by which means they will appear black in all positions to the eye, without any transparency.

BLADDER, *vesica urinaria*, in anatomy, a kind of membranous and fleshy pouch or bottle, capable of dilatation and contraction, situated in the lower part of the abdomen, immediately behind the symphysis of the ossa pubis, and opposite to the beginning of the intestinum rectum. The figure of it is nearly that of a short oval. It is broader on the fore and back sides than on the lateral parts; rounder above than below, when empty; and broader below than above, when full.

It is divided into the body, neck, and bottom; into an interior, posterior, and two lateral parts. The upper part is termed the fundus or bottom,

and the neck is a portion of the lower part, which is contracted like the gullet of some vessels.

The bladder is made up of several coats, almost like the stomach. That part of the external coat which covers the upper, posterior, and lateral sides of the bladder, is the true lamina or membrane of the peritonæum; and the rest of it is surrounded by a cellular substance, by the intervention of which the peritonæum is connected to the muscular coat.

The proper coats are three in number, one muscular, one nervous, and one villous, which is the innermost. The muscular coat is composed of several strata of fleshy fibres, the outermost of which are mostly longitudinal; the next to these are more inclined toward each hand; and the innermost more and more oblique, and they become at length almost transverse. All these fibres intersect each other in various manners, and they are connected together by a fine cellular substance, and may be separated by inflating that substance.

The nervous coat is nearly of the same structure with the tunica nervosa of the stomach.

The internal coat is something granulated and glandular, and a mucilaginous serum is continually discharged through it, which moistens the inner surface of the bladder, and defends it against the acrimony of the urine. It appears sometimes altogether uneven on the inner side, being full of eminences and irregular rugæ when empty, and in its natural state of contraction. These inequalities disappear when the bladder is full, or when it is artificially distended by air, or by injecting any liquid.

The external fibres of the muscular coat are more numerous than the internal; and the most longitudinal anterior fibres form a kind of incurvation round the urachus at the top of the bladder, much like that of one of the fleshy portions which surround the superior orifice of the stomach, and lower extremity of the œsophagus. This incurvation passes behind the urachus.

The portion of the peritonæum which covers the posterior convex side of the bladder, forms a very prominent transverse fold, when the bladder is contracted, which disappears when the bladder is extended. This fold surrounds the posterior half of the bladder, and its two extremities are elongated toward each side, by which elongations a kind of lateral ligaments of the body of the bladder is formed, which are more considerable in children than in adults.

The lower part of the bladder, which deserves the name of fundus much better than the upper part, is perforated by three openings, one anterior and two posterior. The anterior opening is formed by an elongation of all the proper coats, in form of a gullet, turned much in the same manner with
the

the inner orifice of the rostrum of the head of an alembic. This elongation is called the neck of the bladder.

The other two openings in the true fundus of the bladder are formed by the ureters, which, in their course downward, run behind the spermatic vessels, and then behind the lower part of the bladder, approaching near each other. See URETERS.

Each ureter lies between the umbilical artery and vas deferens of the same side; the artery lying on the outside of the ureter, and the vas deferens on the inside.

Afterwards they get between the vasa deferentia and the bladder, crossing these canals; and then, at about a finger's breadth from each other, they begin to pierce the coats of the bladder. They run a little way between the muscular and nervous coats, and open into the bladder obliquely, something nearer each other than when they first entered its coats.

The orifices of the ureters in the bladder are something oval and narrower than the cavity of the ureters immediately above them. The edge of these orifices is very thin, and seems to be formed merely by the union of the internal coat of the bladder with that of the ureters.

The arteries of the bladder are furnished by the hypogastricæ or iliacæ internæ; being rami of the arteria sciatica, epigastrica, and umbilicalis, on each side. The veins come from those of the same names with the arteries.

The nerves of the bladder come from the crurales, and also from the sympathetici maximi, by means of their communication with the crurales. It has likewise some nerves from the plexus mesentericus inferior. *Winslow's Anatomy.*

The diseases of the bladder are the stone, inflammations, ulcers, &c. See the article STONE, &c.

For the other bladders of the body, see the article VESICULA.

AIR-BLADDER, in physiology. See the article AIR-Bladder.

BLADDER-NUT, in botany. See STAPHYLÆA.

BLADDER SENA, in botany. See COLUTEA.

BLADE, in botany, that part of the flower, or florid attire of a plant, which arises out of the concave of the sheath, and, at the top, usually divides into two parts, which are covered with globules of the same nature as those of the apices, but not so copious.

The blade runs through the hollow of the sheath and base, and is fastened to the convex of the seed-case, having its head and sides beset with globules, which through a glass appear like turnip-seeds, and which, in some plants, grow close to foot stalks. These globules, as the blade springs up from within the sheath, are still rubbed off, and so stand like a powder on both. In some plants, as knap-weed,

they seem also to grow on the inside of the sheath, as appears on splitting it with a pin. The head of a blade is divided usually into two; but sometimes, as in cichory, into three parts, which, by degrees, curl outward, like scorpion-grass.

BLADE, in commerce, a thin slender piece of metal, either forged by the hammer, or run and cast in moulds, to be afterwards sharpened to a point, edge, or the like.

BLAFART, in commerce, a small coin, current at Cologne, worth something more than a farthing of our money.

BLAIN, among farriers, a distemper incident to beasts, being a certain bladder growing on the root of the tongue, against the wind-pipe, which swells to such a degree, as to stop the breath. It comes by great chafing and heating of the stomach, and is perceived by the beast's gaping and holding out his tongue, and foaming at the mouth: to cure it, cast the beast, take forth his tongue, and then sitting the bladder, wash it gently with vinegar and a little salt.

BLANCHING, in general, implies the art of bleaching or whitening. See BLEACHING.

BLANCHING of copper is done various ways, so as to make it resemble silver. If it be done for sale, it is felony, by 8 and 9 William III. ch. xxvi.

BLANCHING, in coinage, the operation performed on the planchets or pieces of silver, to give them the requisite lustre and brightness. They also blanch pieces of plate, when they would have them continue white, or have only some parts of them burnished.

Blanching, as it is now practised, is performed by heating the pieces on a kind of peel with a wood-fire, in the manner of a reverberatory; so that the flame passes over the peel. The pieces being sufficiently heated, and cooled again, are put successively to boil in two pans, which are of copper: in these they put water, common salt, and tartar of Montpellier. When they have been well drained of this water in a copper sieve, they throw sand and fresh water over them; and when dry, they are well rubbed with towels.

BLANCHING, among gardeners, an operation whereby certain plants, &c. are rendered whiter, and more tender, than otherwise they would be. One operation is, by tying the leaves up close; this is practised on cabbages, lettuces, &c. in the summer, which makes them fit for use considerably sooner, and particularly those which are not inclinable to turn in, or cabbage, as the gardeners term it. Another method practised, in winter on cellery, endive, dandelion, &c. is by earthing them up to their tops, which not only blanches, but also protects them from the frosts. The operation for so doing, see under their respective articles.

BLANCHING also denotes the operation of covering iron plates with a thin coat or crust of tin.

BLA

BLANK, or **BLANC**, properly signifies white. See **WHITE**.

BLANK, in commerce, a void or unwritten place which merchants sometimes leave in their day-books or journals. It is also a piece of paper, at the bottom of which a person has signed his name, the rest being void. These are commonly intrusted into the hands of arbiters, to be fitted up as they shall think proper, to terminate any dispute or lawsuit.

BLANK-BAR, in law, the same with common bar. See the article **BAR**.

BLANK-TICKETS, in lotteries, those drawn without any prize.

BLANK-VERSE, in the modern poetry, that composed of a certain number of syllables, without the assistance of rhyme. See the articles **VERSE** and **RHYME**.

Point-BLANK. See **POINT-BLANK**.

BLANKET, a coverlet for a bed : a stuff commonly made of white wool, and wrought in a loom like cloth ; with this difference, that they are crossed like ferges.

When they come from the loom, they are sent to the fuller ; and after they have been fulled and well cleaned, they are napped with a fuller's thistle.

There are also blankets made with the hair of several animals, as that of goats, dogs, and others.

The manufacture of blankets is chiefly confined to Witney in Oxfordshire, where it is advanced to that height, that no other place comes near it. Some attribute a great part of the excellency of the Witney blankets to the absterfve, nitrous water of the river Windrush, wherewith they are scoured ; others rather think they owe it to a peculiar way of loose spinning, which the people have thereabouts. Be this as it will, the place has engrossed almost the whole trade of the nation for this commodity ; inasmuch that the wool fit for it centers here from the furthestmost parts of the kingdom. There are said to be at least sixty blanketers in that town, who, amongst them, have at least one hundred and fifty looms, and employ three thousand persons, from children of eight years old, who work out about a hundred packs of wool per week.

BLANQUILLE, in commerce, a small silver coin, current in the kingdom of Morocco, and all that part of the coast of Barbary. It is worth about three halfpence of our money.

BLASPHEMY, an indignity or injury offered to the Almighty, by denying what is his due, and of right belonging to him ; or by attributing to the creature that which is due only to the Creator.

BLAST, in a general sense, denotes any violent explosion of air, whether occasioned by gunpowder, or by the action of a pair of bellows.

BLE

BLASTS, among miners, the same with damps. See the article **DAMP**.

BLAST, or **BLIGHT**, in husbandry. See **BLIGHT**.

BLASTING, a term used by miners for the tearing up rocks, which lie in their way, by the force of gunpowder.

In order to do this, a deep hole is made in the rock, which being charged with gunpowder, they fill it up ; leaving only a touch-hole, with a match to fire the charge.

BLAZE, a white spot in a horse's face.

BLAZING-STAR, the same with comet. See the article **COMET**.

BLAZONING, or **BLAZONRY**, in heraldry, the art of decyphering the arms of noble families.

The word originally signifies the blowing or winding of a horn, and was introduced into heraldry as a term denoting the description of things borne in arms, with their proper significations and intendments, from an ancient custom the heralds, who were judges, had of winding an horn at jousts and tournaments, when they explained and recorded the achievements of knights.

In blazoning a coat of arms, you must always begin with the field, and next proceed to the charge ; and if there be many things borne in the field, you must first name that which is immediately lying upon the field. Your expressions must be very short and expressive, without any expletives, needless repetitions, or particles. Such terms for the colours must be used, as are agreeable to the station and quality of the bearer. All persons beneath the degree of a noble, must have their coats blazoned by colours and metals ; noblemen by precious stones, and kings and princes by planets.

BLEA, in the anatomy of plants, the inner rind or bark. It may be considered as an assemblage of straight fibres ranged vertically and parallel to one another.

While the blea remains any thing soft, and retains somewhat of the nature of bark, it may maintain a feeble vegetation ; but when it is grown absolutely hard and woody, it can no longer contribute thereto.

BLEACHING, the art or method of whitening linens, stuffs, silks, hair, wax, &c.

This art, or rather the different processes in which it consists, being of the utmost importance to several manufactures, the reader will not, we presume, be displeased to find it explained in a particular and intelligent manner.

The proper materials for bleaching either linen yarn, or cloth, are wood-ashes brought from Muscovy and Germany, and Cassoup, also a sort of ashes imported from Dantzick. But the common wood-ashes and weed-ashes made in this kingdom, are as good as the best, unless it be for bleaching cloth of a very high price. He that would bleach well,

well, must be provided with a convenient bleaching-yard, bleaching-house, and all things suitable; for shifts in trade fail in the event. He ought to have his bleaching-yard well watered. The nature of the water ought to be soft, such as will break sope. The yard ought to be so situated, as that in the drought of summer the trenches and pipes may be constantly supplied. As for the bleaching-house, it ought to be furnished with good coppers and boilers, good tubs for bucking, and also stands and vats for keeping the several sorts and degrees of lyes, and other great stands and vats for keeping the milk, or acidulated liquor.

In the bleaching of your yarn, you must first open each bank, and lay it in your bucking-tub; then cover your yarn with cold water, and let it steep for about nine hours: therefore let go that water by means of a cock, which ought to be fixed near the bottom of your tub; and then fill it again with water. Continue thus to steep and cleanse your yarn from its filth, till such time as you perceive that the water is no way foul that comes from it: then withdraw your yarn out of your tub, and rinse it well in clean water. After rinsing it, you must wring out all the water, by wringing three or four hanks at a time: then lay it out to dry in your bleaching-yard; but be sure never to beat or beetle it. By the time your yarn is perfectly dry, you are to be provided with lye proper for bucking. The first bucking you give your yarn, ought to be with your strongest lye. Your yarn being quite dry, you must dip three or four hanks at a time, and lay them in your bucking-tub, in the most equal and even manner that possibly you can; never pressing them too much, to the end the lye may the better pierce and penetrate them. All your yarn being thus laid in your tub, put the remainder of your lye, in which you dip your yarn, into a pot or pan, and make a slow fire under it, taking care not to heat your lye so for the first five hours, whilst you are thus bucking, but that you may be able to endure your hand in it. Your fire made, you must very often take out some of your lye, and pour it upon your yarn in your tub; then you must increase your fire gradually and slowly, so as in four hours time more to bring your lye to boil: during all which time, you must continue to take your lye out of your copper, and put it into your tub by small quantities at a time. When your lye begins to boil, you must let it boil on for three hours, during the whole time lading or pouring your lye out of your copper into your tub; so that you will be twelve hours bucking your yarn. If your lye was strong and good, your yarn will be brought to a yellow colour, if the improper preparing of some flax does not hinder it: but where you find your yarn, or part of it, does not attain to this yellow colour, you must repeat bucking until it answers

your ends. When your yarn is sufficiently bucked for your purpose, you must take it out, rinse it in cold water, and wring it well; taking care to wring but three or four hanks at a time, that it may the better endure the labour. Be sure never to beat or beetle it, as hath been already observed. Then spread it out in your bleaching-yard; where it must lie exposed to the weather for three or four days before you turn it. When that time is over, turn it, and let it lie there till the sile that is undermost be as good a colour as the other. You must water yarn on the bleaching-yard as you do cloth, that it may whiten the sooner, and lie the shorter time upon the green. This bleaching which was just now prescribed to be given to your yarn, is not intended to make it very white, but chiefly to cleanse it from the filth that is incident to it, that your cloth may be the thicker and stronger, and with more ease brought to a colour when it comes to be bleached. Wherefore bleach your yarn for all kinds of cloth, except cambricks and lawns, the yarn whereof should not be bleached before it be woven.

BLEACHING of Linen Cloth. In order to perform this operation, you must begin with it as you did with your yarn, by steeping it in cold water in your tub for nine hours; then change the water on it, till such time as you can perceive that the water is no longer discoloured; rinse, wring, and lay it out to bleach, observing constantly to water it so as never to suffer it to be too dry. When it hath lain three or four days thus on the grass, and is dry, you must take hold of each piece, one after another, by the selvedge, and draw the cloth to you, still holding it in the most even manner that you can, until you come to the farther end, with the corners of which you tie your cloth very loosely in the middle of the folds, and so lay it in your bucking-tub, with the two selvedges upwards. This you must do until you have placed as much cloth in your tub as will cover the bottom of it, taking care not to pack the cloth so close but that your lye may penetrate to all parts equally; and at the same time you must observe, never, if possible, to buck your cloth but when it is very dry. When you have laid the first range of cloth in your tub, you must pour as much milk-warm lye on it as will sufficiently soak through all all parts of your cloth. Then you must lay another range in the same manner as you did the first; pour on more lye until that be soaked as the other was; and continue to do so till your tub be full. That done, you must begin to buck for twelve hours together, observing the directions, in relation to the fire, given for the former article. Your two first buckings ought to be of very strong lye; but afterwards you should abate of that strength in proportion as your cloth grows nearer to its perfection of whiteness, lest you make it rotten

and unserviceable by over-strong lye. After each bucking you must carry it straight to the bleaching-yard, where it ought to lie forty-eight hours. This you must perform successively as many times as you see occasion, according to the nature of the cloth, from the buck to the bleaching-yard, and from the bleaching-yard to the buck, before you begin to use it with milk; still giving it weaker lye after the two first buckings, and constantly observing to water your cloth on the grass, so as never to suffer it to be dry during these bleachings. It is impossible to prescribe a certain rule, or to direct the precise number of buckings that ought to be given to cloth, because that depends on the sorts or kinds you are to bleach; and therefore the experience and judgment of the bleacher must guide him therein. Your thin fine cloths will bleach much sooner than your coarse or stiff stubborn cloths will do: but both sorts must be dry when you put them into the milk; or which will answer the same purpose, a quantity of water rendered acid by oil of vitriol, in the proportion of half an ounce of the latter to a gallon of the former.

The milking of cloth, or laying it in an acidulated liquor, was not used till of late; but it is found by experience to contribute greatly to bring cloth to a good colour. It has been already observed, that you must have large tubs or vats for the keeping of your milk. These vats, which should hold a ton or two a-piece, you ought to keep full of butter-milk, or sour milk, as it is commonly called, skimmed milk, whey, and the like, mixed together; there to stand and four until you have occasion to use them. It is very rare that your milk proves too sour; but if at any time it should, abate its sourness by adding cold water. When your cloth is dry, and ready to be milked, have a great tub with milk set half-way in the ground. Your cloth being well soaked therein, you must press it down with heavy planks or weights, so as it may not be raised by the fermentation that will be in your milk or acid liquor. When the cloth has lain a-while, take care that these weights be sufficient; and that your planks be neither of new oak or alder, for those woods spoil and stain cloth very much, as will also several sorts of stones, if laid upon cloth either in the tubs or in the field. Thus your cloth must steep for at least forty-eight hours; or, if you please, for three days and three nights; for it will be so much the better for the cloth: then spread it on the grass, and water it well, to prevent its drying with the milk or acid in it: when this is sufficiently done by watering, you must rinse the cloth, and wash it well with a lather of sope. Your next business is to buck the cloth again just as it comes from the sope-suds; and when bucked, you must, without further rinsing, spread it on the grass in your bleaching-yard: there it must remain exposed to the air for two days and

two nights, and be constantly watered in the day-time, when you lay it out to bleach. This operation must be repeated six, seven, or eight times successively, until you perceive your cloth is come to the colour you desire to give it; that is, you must milk, then bleach, then wash, then sope, and buck by turns, until you attain your end; for it is impossible to propose a certain rule, because of the great variety of cloth: only this must be observed, that each time you buck, you must spend twelve hours, during all which time you ought to be constantly lading or pouring the lye into your tub, according to the former directions; for otherwise you may chance to burn your cloth, especially when the lye grows hot. This rule is also constantly to be observed, that your cloth be very dry when you lay it in the milk or acid liquor. This last time you milk your cloths, you ought, instead of the usual washing or rinsing, to lay them in an open cistern; where people with clean feet should tread them very well for half an hour at least. That done, wash them with clean water, until you perceive the fluid to be no way discoloured: then having made your bucking-tub very clean, lay your cloths in it just as you did at first, and steep them in warm water for an hour: then let go that water, and steep them a second time in water somewhat warmer, for an hour longer: let that water go likewise, and steep your cloths a third time in water yet warmer than the former; but not so hot as to boil. This last steeping need not be near so long as the preceding; half an hour is sufficient. Then take out your cloth, rinse and wring it well, that it may be cleansed from the lye, milk, or acid liquor, and sope, and made more susceptible of receiving the starch and blue; which is the next operation.

It is impossible to prescribe a certain rule for preparing of starch to dress your cloth, because of the great variety of cloths which must be made: fine thin cloths require a thicker and more substantial starch than coarser cloths do; therefore it is requisite that bleachers should have some experience and knowledge therein. Every laundress knows how to make starch, and prepare it for the beautifying of her linen: but the starch made use of in this trade is much thinner than theirs. The way to make it is this: Fill the boiler or pan, wherein you design to make your starch, about three quarters full of water; when the water boils, pour into it as much starch dissolved in water, as will completely fill your boiler; keep it stirring perpetually, lest it burn, and let it boil for half an hour, or thereabouts; then take it off the fire, strain it into another vessel with warm water, in proportion to the cloth you design to dress, taking great care to keep it stirring, breaking, and dissolving the clods of starch, that the whole may be of an equal thickness or consistency. When this part of the

the operation is finished, mix powder blue in water, in such proportion as you would give your cloth a higher or a lower colour, and add it to your starch prepared as above. By this means you may make your starch thicker or thinner, as you think will be best adapted to your cloth. Take great care never to use indigo, or stone-blue; because it gives a dull dark colour.

When you have thus prepared your water for starching and bluing, put your cloth into it; and when it is well soaked, take it out, wring it very hard, and spread it on the grass in your bleaching-yard to dry. You will generally find that the blue will settle in some parts of your cloth more than in others: in which case you must, with a clean cloth wet in water, rub such parts till you bring them down to the colour they ought to have. Your cloths being now well starched and blued, according to the circumstances or nature thereof, and being very dry, either fold them up yourself, or send them to a lapper.

BLEACHING of Hair is done by spreading the hair to be bleached upon the grass, in the same manner as linen, after it has been first washed out in a lixivious water.

This lye, with the force of the sun and air, brings the hair to so perfect a whiteness, that the most experienced person may be deceived therein; there being scarce any way of detecting the artifice, but by boiling and drying it; which leaves the hair of the colour of a dead walnut-tree leaf.

BLEACHING of Silk. The silk, being yet raw, is put into a linen bag, and thrown into a vessel of boiling river water, in which sope has been dissolved, and thus boiled for two or three hours; the bag being turned several times, taken out and beaten, then washed out in cold water, and wrung out slightly, and thrown into a vessel of cold water, mixed with sope and a little indigo.

The indigo gives it the bluish cast that is observable in white silks.

When it has been taken out of the second vessel, it is wrung out, and all the water and sope squeezed out, shook out to untwist and separate the threads, and hung up in the air in a kind of stove, made on purpose, in which sulphur is burnt, the vapour of which gives the last degree of whiteness to the silk.

BLEACHING of Woollen Stuff. There are three methods of whitening woollen stuffs; the first is with water and sope, the second is with vapour of sulphur, the third with chalk, indigo, and vapour of sulphur.

For the first, when the stuffs are come from the fulling-mill, they are to be put into soped water pretty hot, and worked afresh by force of arms over a bench, which finishes the whitening which the fulling-mill had begun; in the last place they are to be washed out in fair water.

and dried; this is called the natural way of bleaching.

The second method is what is commonly called bleaching by the flower; the stuff is first washed in river water, and then put to dry on poles, and when it is half dry, spread out in a kind of stove, wherein sulphur is burnt, the vapour of which diffusing itself, sticks by little and little over all the stuffs, and gives it a fine whitening.

The third method is thus; After the stuffs have been washed, they are to be thrown into cold water, impregnated with chalk and indigo, in which they are well agitated: they are washed afresh in elder water, then half dried on poles, and then spread in a stove to receive the vapour of the sulphur, which finishes the bleaching.

This is to be remembered, that when a stuff has once received the steam of sulphur, it will scarce receive any beautiful dye, except black and blue.

BLEACHING of Wax, the operation of changing the colour of the yellow into a beautiful white; it is done in the following manner.

The common yellow wax is first reduced into small grains, by melting it, and throwing it while hot into cold water, or spreading it into very thin cakes. The wax thus granulated or flatted, is placed in the open air on linen cloths, where it remains night and day, it being necessary that it be exposed both to the rays of the sun, and the influence of the dew. After thus lying a considerable time, it is again melted and granulated, or flatted into cakes, and once more exposed to the action of the sun and dew. These operations are alternately performed till the wax has acquired the requisite degree of whiteness.

When the sun and dew have perfectly bleached the wax, it is melted for the last time, taken out of the copper with a ladle, and poured, by means of a double funnel, into shallow moulds or round cavities formed in a board, the moulds being previously wetted with cold water, that the wax may not stick to them; and in this manner the cakes of white wax we see in the shops are made. These cakes are then taken out of the moulds, and again exposed to the action of the air, dew, and sun, for two days and two nights, in order to dry them thoroughly, and render them more transparent.

BLEEDING, or BLOOD-LETTING, the operation of taking blood from any part of the body, either by the lancet, leeches, or cupping. See **PHLEBOTOMY, CUPPING, &c.**

Dr. Pringle observes, that bleeding is the most indispensable of all remedies in inflammatory diseases; to the delaying of which too long, or not repeating it, are chiefly owing the bad consequences of colds, as well as dangerous fevers, rheumatisms, and consumptions. He observes farther, that, in general, young practitioners are apt to be too sparing letting blood, by which means many lives are lost: for a surgeon

may be assured a soldier will never complain of a cough, or pains with inflammatory symptoms, wherein bleeding is not necessary; and from the fineness of the blood, and continuance of the complaints, he is to judge of the necessity of repeating it, which, in case of a stitch, or difficult breathing, is never to be delayed. In inflammatory cases, from twelve to fifteen ounces may be taken for the first bleeding, and somewhat less for all the rest; and when it is necessary to exceed this quantity, it may be proper to follow Celsus's rule, in minding the colour of the blood whilst it flows, and when it is of a blackish cast, which is always the case in difficult breathing and great inflammations, to let it run till it becomes more florid. In all cases where plentiful bleeding is indicated, it is best to do it in bed, to prevent fainting: and we may observe, that a person will bear the loss of a much greater quantity of blood, if the stream is small, than by a large orifice, which some have thought necessary for making a more speedy revulsion.

Bleeding is highly necessary in the phrenitis, ophthalmia, quinsy, rheumatism, cough, hectic fits, and, in general, in all inflammatory cases. *Pringle's Observ. on the Diseases of the Army.*

It is to be observed, however, that, in malignant and putrid disorders, bleeding frequently renders them more malignant, and therefore to be omitted, or at least not repeated, unless there appear evident marks of inflammations.

BLEEDING at the Nose, an hæmorrhage from that organ of the body, owing to the more plentiful apulse of blood to the nostrils by a stronger motion of the heart, whereby the small arteries in the pituitary coat become turgid, and too much distended, till at length they gape, and the blood rushes out.

If the bleeding is very inordinate, it will be proper to use cooling emulsions, gentle or strong opiates to moderate the spastic strictures, as occasion shall require. Camphire, mixed with nitre and calx of antimony, will be highly necessary, if the matter of exanthemata or cutaneous eruptions is the cause of the hæmorrhage, as is often the case.

A revulsion may be made from the head by bleeding in the lower parts; then by temperate pediluvia, and putting the hands into warm water.

As there is often an acrid bilious matter lodged in the hypochondria, the parent of wind and spasms, the powder of rhubarb will be proper, mixed with a few grains of tartar vitriolate and nitre; as also emollient and carminative clysters, with a due proportion of oil.

Externally, refrigerants may be mixed with discutients, and applied to the forehead, nose and neck.

But it must be noted, that when the patient is plethoric, the bleeding must not be stopped hastily, if at all; nor when the menses in women have

been suppressed, or the lochia, or the bleeding piles in men accustomed thereto; much less must a stoppage be attempted when the bleeding itself is periodical.

In persons of a bilious constitution, cold water alone drank freely, has had a good effect.

BLEND-METAL Iron, a coarse sort of iron from Staffordshire mines, used for making nails and heavy ware; in some places also for horse-shoes.

BLEYME, in farriery, an inflammation in a horse's hoof, occasioned by blood putrified in the inner part of the coffin towards the heel, between the sole and the coffin-bone.

There are three sorts of bleymes; the first, bred in spoiled wrinkled feet with narrow heels, are usually seated in the inward or weakest quarter; the second, besides the usual symptoms of the first, infects the gristle, and must be extirpated, as in the cure of a quitter bone; the third is occasioned by small stones and gravel between the shoe and the sole. For a cure, they pare the foot, let out the matter, if any, and dress the sore, like the prick of the nail.

BLIGHT. There is nothing more common in the beginning of summer, than to see the leaves of peaches, nectarines, and cherries, curled up and blighted, which leaves on examination are found covered with little insects, some blackish, others green, some winged, and others without wings; these creatures bring forth their young alive and perfect, and if their bodies be opened, several perfect embryos will be seen therein. It remains a doubt whence, and by what means, these insects are conveyed upon the young sprouting leaves, which at the same time are always covered with a glutinous and honey-like moisture; but diligent observations are likely to discover the secret. Trees in this condition are visited by multitudes of ants, which hurt not the trees, (as some have erroneously conjectured) but do them service, by devouring these vermin that infect them.

It is evident that, from the great increase of these insects, fruit and other trees, with most sorts of plants, sustain great damage, and more especially when they co-operate with blights.

Some have supposed, that blights are usually produced by an easterly wind, which brings vast quantities of insects eggs along with it from some distant place; which, being lodged upon the surface of the leaves and flowers of fruit-trees, cause them to shrivel up and perish. To cure this distemper, they advise the burning of wet litter on the windward side of the trees, that the smoke may be carried to them by the wind, which they suppose will stifle and destroy those insects, and thereby cure the distemper. Others direct the use of tobacco-dust, or to wash the trees with water wherein tobacco-stalks have been infused for twelve hours,

or to scatter pepper-dust upon the blossoms of fruit trees.

But the true causes of blights are from a continued dry easterly wind, for several days together, without the intervention of showers, or any morning dew, by which the perspiration in the tender blossoms is stopped, so that in a short time their colour is changed, and they wither and decay; and if it so happen, that there is a long continuance of the same weather, it equally affects the tender leaves; for their perspiring matter is hereby thickened and rendered glutinous, closely adhering to the surface of the leaves; and becomes proper nutriment to those small insects, which are always found preying upon the leaves and tender branches of fruit-trees, whenever this blight happens; but it is not these insects which are the first cause of blights, as hath been imagined by some, though it must be allowed, that, whenever these insects meet with such a proper food, they multiply exceedingly, and are instrumental in promoting the distemper; so that many times, when the season proves favourable to them, and no proper care has been taken to prevent the mischief, it is surprising to think how whole walls of trees have suffered by this infection.

The best remedy, yet known, for this distemper, is, gently to wash and sprinkle over the trees, from time to time, with common water (that is, such as had not any thing steeped in it); and the sooner this is performed (whenever we apprehend danger) the better, also to water well the roots (particularly in dry lands); and if the young and tender shoots seem to be much infected, wash them with a woollen cloth, so as to clear them, if possible, from all this glutinous matter, that their respiration and perspiration may not be obstructed; and if we place some broad flat pans or tubs of water near the trees, that the vapours exhaled from it may be received by the trees, it will keep their tender parts in a ductile state, and greatly help them. This should be done early in the day, that the moisture may be exhaled before the cold of the night comes on, especially if the nights are frosty; nor should it be done when the sun shines very hot upon the wall, which might scorch up the tender blossoms.

But there is another sort of blight, that sometimes happens in April or May, and is often very destructive to gardens, orchards, and open plantations, and against which we know of no remedy. This is what is called a fire-blast, which, in a few hours, not only destroys the fruit and leaves, but, many times, parts of trees, and sometimes intire trees have been killed by it.

This is supposed to be effected by volumes of transparent flying vapours, which, among the many forms they revolve into, may sometimes approach so near to an hemisphere, or hemicylinder, either in

their upper or lower surfaces, as thereby to make the beams of the sun converge enough to scorch the plants or trees they fall upon, in proportion to the greater or less convergency of the sun's rays.

Boerhaave observes, that those white clouds, which appear in summer-time, are, as it were, so many mirrors, and occasion excessive heat: these cloudy mirrors are sometimes round, sometimes concave, polygonous, &c. When the face of the heavens is covered with such white clouds, the sun, shining among them, must produce a vehement heat; since many of his rays, which would otherwise, perhaps, never touch our earth, are hereby reflected to us: thus, if the sun be on one side, and the clouds on the opposite, they will be perfect burning-glasses: and hence the phenomenon of thunder.

I have sometimes, continues he, observed a kind of hollow clouds, full of hail and snow, during which the heat was extreme; since, by such condensation, they were enabled to reflect much more strongly: after this came a sharp cold, and then the clouds discharged their hail in great quantities, to which succeeded a moderate warmth. Frozen concave clouds therefore, by their great reflections, produce a vigorous heat; and the same, when resolved, excessive cold.

Whence, as Dr. Hales observes, we see, that blasts may be occasioned by the reflexions of the clouds, as well as by the above-mentioned refraction of dense transparent vapours.

There is no other remedy against this evil, but to make choice of clear healthy situations, that the air may pass freely between the trees, to dissipate those vapours before they are formed into such volumes. For blights more frequently happen in close plantations, (where the stagnating vapours from the earth, and the plentiful perspirations from the trees, are pent in for want of a free air to dissipate and dispel them, which are often observed in still weather, to ascend in so plentiful a manner, as to be seen by the naked eye, but especially with reflecting telescopes, so as to make a clear and distinct object become dim and tremulous) than in those that are planted at a greater distance, or are not surrounded with hills or woods; this directs us in the first planting of orchards, &c. that we should allow a greater distance between the trees, that the air may more freely pass, also the fruits which are produced in this clearer air, will be much better tasted, than those that are surrounded with a thick rancid air; for as fruits are often in a respiring state, so they consequently, by imbibing a part of these vapours, are rendered crude and ill-tasted, which is often the case with great part of our fruits in England.

BLIND, deprived of the sense of sight. See the article BLINDNESS.

BLI

BLIND is also used in speaking of vessels which are not perforated.

Thus the chemists say, a blind alembic; that is, one which has no aperture. A tube is said to be a blind one, when it is closed at top.

Pore-BLIND, or **Pur-BLIND**, is said of a person who is very short-sighted.

Moon-BLIND, denotes horses that lose their sight at certain times of the moon; to cure which, take half an ounce of lapis calaminaris; heat it red-hot, and quench it in a quarter of a pint of plantain-water, or white-wine: to this add half a dram of aloes, and a spoonful of camphor, in powder; and letting them dissolve, drop part of it into the horse's eye.

BLIND, among traders, a kind of false light which they have in their warehouses and shops, to prevent too great a light from diminishing the lustre of their linens and stuffs.

BLIND, or **BLINDE**, among mineralists, a kind of lead marcasite; by our miners called mock-ore, mock-lead, and wild-lead.

It is a mineral mass, flaky, glossy, and breaking in angles, much like the potters lead-ore, only of a colour more dusky, and approaching to black. In it are veins of a yellow shining marcasite, with a little white spar, and on one side a greenish arguginous matter. On a trial by the fire, it yielded a very little copper, less lead, and no tin. It is very obstinate, several attempts having been made with the alkaline fluxes to run it, in vain.

BLINDNESS, a total privation of sight, arising from an obstruction of the functions of the organs of sight, or from an entire deprivation of them.

The causes of blindness are various, proceeding from cataracts, gutta serenas, &c. There are also periodical blindness, as a defect of sight in some towards night, in others only in the day; the former of which is termed nyctalopia, the latter hemeralopia. See the articles **NYCTALOPIA**, &c.

BLINDNESS, in farriery. See the article **EYE**.

BLINDS, in military affairs, are a kind of frames, composed of four pieces of wood, two of which are five or six feet in length; the longest are pointed at both ends, and the two others are fastened towards the extremities of the former, at about fifteen inches from their points, the whole forming a rectangular parallelogram, the long sides of which project or jut out beyond the other about fifteen inches.

The blinds are supported against the banks of the trenches, and are so placed as that their longer sides are in a vertical position. Their points at the bottom serve to fix them in the earth, and those at the top to hold the fascines that are placed upon them; they are placed along both sides of the banks of the trenches, and others are also laid

BLO

horizontally on the top of them; the latter being also covered with fascines, so as that the trench is formed into a kind of covered gallery. This disposition is made when the works are far advanced, and in places where the grenades of the besieged too much annoy the soldiers in the trenches.

The term **blind** is also used to express a kind of hurdle, made of the branches of trees, behind which the soldiers may carry on their works without being seen by the enemy.

BLITE, *Blitum*, in botany, a genus of monandrious plants; the flower is apetalous, but the empalement, which is tripartite and premanent, becomes an oval compressed capsule, containing a seed nearly the same size. The different species of this plant are natives of foreign countries, one of which grows naturally in Spain and Portugal. It is annual, and hath leaves resembling spinach. The stalk rises about a foot and a half high, the lower part of which is furnished with leaves of the same form with those at bottom, but smaller; the upper part of the stalk hath flowers coming out in small heads at every joint, and is terminated by a small cluster of the same. When the flowers are decayed, the little heads swell to the size of wood-strawberries, and when ripe have the same appearance; they are very succulent, and full of a purple juice, which stains the hands of those who bruise them, of a deep purple colour. All the sorts of blite are raised with little care; for if the seeds are permitted to shed, they will come up in the spring, and make a pretty appearance in the succeeding summer.

Blite, on account of its cooling and emollient qualities, is recommended in dysenteries and spitting of blood.

BLOCKS, in the marine, little wooden machines artfully disposed amongst the rigging of a ship, so as to give additional power to the ropes that command the necessary mechanism aloft; such as extending, contracting, or traversing the sails, by hauling in certain cords on the deck.

It would be difficult to describe the figure of a block, as they are of such various sizes, shapes, and powers, single, double, and even six and seven-fold, so denominated from the number of sheaves they contain. A common single block approaches nearest to the figure of a long spheroid, somewhat flattened in the middle, and is hollowed parallel with the flat part, so as to receive a little cylindrical wheel, formed of *lignum vite*, or other hard wood, called a sheave, which has sufficient room to turn in the block; a pin is then fixed in the center of the block, upon which the sheave turns as upon an axis: blocks are thus prepared before they come abroad; they are afterwards fastened by ropes made like a ring, and fitted to a notch in their outside, and suspended amongst the masts and shrouds; those of five or six sheaves are nearest

Fig. 11.

nearer the form of a cylinder, and are only used for lifting weighty bodies, as great masts, pieces of marble, &c.

Plate XX. *fig. 5.* represents a single block; *fig. 6.* and *7.* double and treble; *8.* a cat-block; *9.* a swivel iron-bound block; *10.* a top-block, and *11.* a clue-garnet block.

The cat-block is for drawing the anchor up to the cat-head.

The swivel in the iron-bound block is to turn it, that the parts of the purchase affixed to it, called the taicle, may not be twisted round each other, which would greatly diminish its force.

The top-block, *fig. 10.* is to hoist up or lower the top-masts, and is hooked in a bolt driven in the cap. See the article CAP.

The clue-garnet blocks, *fig. 11.* are fixed to the clews or lower corners of the sails, and are for drawing them up to the yard, when the sail is to be contracted or furled. See CLUE-GARNET.

BLOCKADING, in military affairs, is to surround a place with different bodies of troops, who shut up all the avenues on every side, and permit nothing to go in or out of the place.

The design of the blockade is to oblige those who are shut up in the town to consume all their provisions, and compel them to surrender for want of subsistence.

By this it appears that a blockade must last a long time, when the place is well provided with necessaries; for which reason this method of reducing a town is seldom taken, but when there is reason to believe the magazines are unprovided, or rather when the nature or situation of the place permit not the approaches to be made, which are necessary to attack it in the usual way.

Maritime towns which have a port, are in much the same case as other towns, when their port can be blocked up, and the besiegers are masters of the sea, and can prevent succours from being conveyed that way into the place. If the sea be open, or if only a few vessels can find means now and then to enter the port secretly and by stealth, the place being continually relieved with fresh troops and provisions, may sustain a very long siege. Oftend, when besieged by the Spaniards, held out above three years; the succours which it continually received by sea, furnished it with the means of making this long defence.

The siege of such places therefore ought never to be undertaken, but when the besiegers have it in their power to prevent the place from receiving any succour by sea.

It is not sufficient to have a numerous fleet before the port, because the enemy may find means to cause some small barks laden with provisions to slip the fleet in the night. The most effectual method of intercepting these succours, if the situation permits, is to construct a bank, or staccado, as was

contrived by cardinal Richlieu, for entirely blocking up the port of Rochelle. There are, indeed, but few situations which admit of this expedient; and besides, the execution of it is so difficult, and takes up so much time, that it cannot be proposed as a method to be practised in the attack of all maritime towns. All that can be substituted instead of this tedious and laborious work, is a careful and diligent watch aboard the fleet, to prevent as much as possible, any bark or vessel from entering the port of the town. This direction being well observed, the attacks on the land are carried on as usual, the neighbourhood of the sea causing no alteration therein: on the contrary, the several works of the fortification may be cannonaded from the ships, in order to favour the progress of the attack.

BLOMARY, or BLOOMARY, in metallurgy, the first forge through which iron passes, after it is melted out of the ore.

BLOOD, *Sanguis*, a red liquor circulating through the arteries, veins, and other vessels of animal bodies; and serving for the support of life, and nourishment of all their parts.

Blood is the great source from whence all the other liquors of the body are derived; for the origin of which see the article SANGUIFICATION.

Recent blood is equally fluid, and in taste somewhat saline. Viewed by a microscope, it appears composed of numerous red globules swimming in a transparent fluid.

On standing for a little time, it separates into a thick crassamentum, and fluid serum. By agitation, it continues fluid: a consistent polypous matter adheres to the stirrer, which, by repeated ablution with water, becomes white.

Received from the vein in warm water, it deposits a quantity of transparent filamentous matter, the red portion continuing dissolved in the water. On evaporating the fluid, a red powdery substance is left.

It congeals by frost, and becomes fluid again by warmth: after the liquefaction it quickly putrefies. Fluid and florid blood, exposed to a temperate air, putrefies sooner than in such as is more dense.

Inspissated to dryness, it leaves a dark-coloured mass, amounting at a medium to about one fourth the weight of the blood, of a dark colour, and a bitter saline taste, easily inflammable, burning with a bluish flame. The exsiccated blood is not dissoluble in acid or in alkaline liquors, but gives some tincture to water and to spirit of wine, and is more powerfully acted upon by dulcified spirit of nitre.

Recent blood is coagulated by the mineral acids, and by most of the combinations of them with earthy and metallic bodies. With vegetable acids, and with solutions of neutral salts, it mingles equally without coagulation. Alkalies, both fixed and volatile, render it more fluid, and preserve it from coagulating.

The serum of blood is more saline than the crassamentum, and does not so speedily putrefy. It freezes with somewhat more difficulty than pure water, and its aqueous part evaporates, by a gentle warmth, somewhat more readily, leaving about one twelfth the weight of the serum of a solid yellowish pellucid matter. Exposed to a heat a little greater than that of the human body, it coagulates into a solid mass, without any considerable evaporation. Both this coagulum, and the inspissated serum, are readily inflammable in the fire, not dissoluble in water, or in spirit of wine, in acid, or in alkaline liquors.

Blood, in medicine, claims the most attentive regard of physicians. An excess of its quantity produces a plethora, lethargy, &c. Fevers are the consequence of its too rapid motion, and obstructions, of its viscosity and languor.

The too great heat and viscosity of the blood are its prevailing disorders in a country like this, where people live high, and drink hot inflammable liquors. Besides temperance, and using water as beverage, the milder preparations of mercury contribute greatly to cool and dilute the blood: such are aethiops and cinnabar, if given in moderate doses, so as not to affect the stomach, or excite a salivation.

Thickness of the blood is another distemperature, proceeding from a plethora, and diminution of its motion; from whence arise obstructions, stagnations, hypochondriac and hyseric affections, &c. The incubus, or night-mare, is also owing to the same cause.

Spitting of Blood is cured by copious bleeding every third day, to the fourth time. Gentle purging is likewise recommended; and for appeasing the commotion of the blood, spirit of vitriol, but more especially the tincture of roses made therewith. A milk diet is also preferable to any other; and after the cure is completed, it will be necessary, by way of prevention, to bleed once in six months for several years together.

Blood, in farriery, a distemper in the backs of cattle, which will make a beast go as if he drew his head aside, or after him. In order to cure it, you should slit the length of two joints under his tail, and so let him bleed well; but if he bleeds too much, knit his tail next the body, and then bind salt and nettles bruised into it.

Blood of Christ, the name of a military order instituted at Mantua in 1608. The number of knights was restricted to twenty, besides the grand-master. Their device was, *Domine probasti me, or Nihil hoc, triste, recepta.*

Blood of Christ is also the name of a congregation of nuns at Paris.

BLOOD-FLOWER, in botany. See HEMANTHUS.

BLOOD-SPAVIN. See the article SPAVIN.

BLOOD-STONE. See HÆMATITES.
BLOODY-FLUX. See the articles FLUX and DYSENTERY.

BLOODY-HAND is when a trespasser is apprehended in a forest with his hands or other parts bloody; which is a circumstance of his having killed the deer, though he be not found chasing or hunting them.

BLOOM, a mass of iron after having undergone the first hammering, called blomary. See the article BLOMARY.

BLOSSOM, or BLOOM, denotes the flowers of plants, and particularly those of fruit-trees.

BLOSSOM, or PEACH-COLOURED, in the manege, a term applied to a horse that has his hair white, but intermixed all over with sorrel and bay hairs. Such horses are so insensible, and hard both in the mouth and the flanks, that they are scarce valued; besides, they are apt to turn blind.

BLOW-PIPE, among jewellers and other artificers, is a glass tube, of a length and thickness at discretion, wherewith they quicken the flame of their lamp, by blowing through it with their mouth. It is used in works of quicker dispatch, which do not need the bellows.

BLOWING of a Flower, among florists, signifies the care they have taken to produce their flowers in the highest perfection, and in particular for auriculas and carnations. The usual method (respecting carnations) is, when the flower stems begin to put forth, (or as the florists call it to spindle) to place by each plant a straight stick, four feet long, and tie the spindles to it as they shoot. When the flower-buds appear, there should be gathered off all the small buds, reserving only a few of the largest to blossom; these are frequently apt to burst, whereby the beauty of the flower is considerably diminished, to prevent which the pod should be slightly tied round the middle. When the blossoms begin to expand, they should be shaded by a board fastened to the top of the stick, in order to preserve their beauty the longer; though with some blossoms, it is necessary to place glasses over them, in order to draw out the interior petals, so as to form the whole flower as nearly hemispherical as possible.

BLOWING of Glass, one of the methods of forming the divers kinds of works in the glass manufacture.

The workman dips his blowing-pipe into the melting-pot, and by turning it about, the metal sticks to the iron more firmly than turpentine. This he repeats three times, which is called gathering; he then rolls the end of his instrument with the hot metal thereon, on a piece of polished iron, and the workman perceiving there is metal enough on the pipe, claps his mouth immediately to the other end of it, and blows gently through the iron tube, till the metal lengthens like a bladder about a

foot.

foot: then he rolls it on a marble stone a little while to polish it, and blows a second time, by which means he brings it into the form of a globe, of about eighteen or twenty inches in circumference. This globe may be flattened by returning it to the furnace, and brought into any form by stamp-irons, which are always ready.

When the glass is thus blown, it is cut off at the collet or neck, which is the narrow part that stuck to the iron. The method of performing this is as follows: The pipe is rested on an iron bar, close to the collet; then a drop of cold water being laid on the collet, it will crack about a quarter of an inch, which with a slight blow, or cut with the shears, will immediately separate the collet.

After this is done, the operator dips the iron-rod into the melting-pot, by which he extracts as much metal as serves to attract the glass he has made, to which he now fixes this rod at the bottom of his work, opposite to the opening made by the breaking of the collet. In this position the glass is carried to the great bocca, or mouth of the oven, to be heated, by which means it is again put into such a soft state, that, by the help of an iron instrument it can be pierced, opened, and widened, without breaking. But the vessel is not finished till it is returned to the great bocca, where it being again heated thoroughly, and turned quickly about with a circular motion, it will open to any size, by the means of the heat and motion: and by this means we come to learn the cause why the edges of all bowls and glasses, &c. are thicker than the other parts of the same glasses; because, in the turning it about in the heat, the edge thickens, and the glass being as it were doubled in that part, the circumference appears like a selvedge. If there remain any superfluities, they are cut off with the shears; for, till the glass is cool, it remains in a soft flexible state. It is therefore taken from the bocca, and carried to an earthen bench covered with brands, which are coals extinguished, keeping it turning; because that motion prevents its settling, and preserves an evenness in the face of the glass; where as it cools, it comes to its consistency, being first cleared from the iron-rod, by a slight stroke with the hand of the workman.

If the vessel conceived in the workman's mind, and whose body is already made, requires a foot, or a handle, or any other member, or decoration, he makes it separate; and now essays to join them with the help of the hot metal, which he takes out of the pot with his iron-rod; but the glass is not brought to its true hardness, till it has passed the leer or annealing oven.

Blowing of Crown Glass. The above method is applicable to the working of crown glass, till the blowing-iron or pipe has been dipped the third time; for then, instead of rounding it, the workman blows, and at the same time rolls or kneads

the metal upon the iron plate, into the form of a cylinder. This cylinder is put again to the fire, and blown a second time, and is thus repeated, till it is extended to the dimensions required; the side to which the pipe is fixed diminishing gradually, till it ends in a conical form. While the glass is thus flexible, a small piece of metal is added in the center, opposite to the pipe fixed to an iron-rod, and with a drop of cold water and a slight blow is knocked off from the pipe.

The cylinder, being now open at one end, is carried back to the flashing furnace, where the mouth or aperture of the cylinder is put to warm at the nose hole, adjoining to the flashing furnace, and when at a proper degree of heat is opened on an instrument for that purpose in a circular form of about four or five inches diameter. This done, it is carried to the flashing furnace, where a brisk fire is continually kept, and by turning it quickly about in the fire in a circular motion, immediately opens and forms itself into a table glass, and by the assistance of a pair of shears, is cut off from the iron rod, which causes the knot or knob in the middle: this done, it is carried upon forks, and put into the annealing furnace, where it remains for thirty hours. In this furnace upwards of an hundred tables of glass may lie at a time without any injury to each other, by separating them into tens, with an iron slider between, which diminishes the weight by dividing it, and keeps the tables flat and even.

This was the method formerly made use of for making large plate glass, looking-glasses, &c. But the workmen by this method could never exceed fifty inches in length, and a proportional breadth; because what were larger were always found to warp, which prevented them from regularly reflecting the objects, and wanted substance to bear the necessary grinding. These imperfections have been removed by an invention of the Sieur Abraham Thevart, a Frenchman, about the year 1688, of casting or running large plates of glass. See *Casting of Glass*.

For the manner of founding glass, and the materials of which it is composed; see the article GLASS.

BLOWING of Tin denotes the melting its ore, after being first burned to destroy the mundic.

BLUBBER denotes the fat of whales, and other large sea animals, whereof is made train-oil. See the article OIL.

BLUE, otherwise called **AZURE**, is one of the primitive colours of the rays of light.

In oil and miniature, they also use indigo prepared; as also a fictitious ultramarine. See the articles **ULTRAMARINE** and **INDIGO**.

Turnsole BLUE is used in painting on wood, and is made of the seed of that plant. The way of preparing it is, to boil four ounces of turnsole in a

pint and a half of water, in which lime has been slacked.

Dyers BLUE is one of their simple or mother colours, used in the composition of others. It is made of woad, indigo, and a pafel brought from Normandy. Some dyers heighten their blue by adding brazil and other woods. See *WOAD* and *INDIGO*.

A BLUE for painting or staining of Glafs. Take fine white sand twelve ounces, zaffer, and minium, of each three ounces; reduce them to a fine powder in a bell-metal mortar; then putting the powder into a very strong crucible, cover it and lute it well, and being dry, calcine it over a quick fire for an hour: take out the matter and pound it; then to sixteen ounces of this powder, add fourteen of nitre powder; mix them well together, and put them into the crucible again; cover and lute it, and calcine for two hours on a very strong fire.

Prussian BLUE. This blue is next to ultramarine for beauty, if it be used in oil. This colour does not grind well in water. See *PRUSSIAN-BLUE*.

BLUE Bice is a colour of good brightness, next to Prussian blue, and also a colour of a body, and will flow pretty well in the pencil.

Saunders BLUE is also of very good use, and may serve as a shade to ultramarine or the blue bice, where the shades are not required to be very deep, and is of itself a pleasant blue, to be laid between the light and shades of such a flower as is of a mazarine blue.

Laemus, or Litmus BLUE. This is a beautiful blue, and will run in a pen as free as ink. It is made of lacmus, and prepared thus: Take an ounce of lacmus, and boil it in a pint of small beer wort, till the colour is as strong as you would have it; then pour it off the liquor into a gallipot, and let it cool for use. This affords a beautiful colour, has extraordinary effects, and is a holding colour; if it be touched with aqua-fortis, it immediately changes to a fine crimson, little inferior to carmine.

BLUE Japan. Take gum-water, what quantity you please, and white lead a sufficient quantity, grind them well upon porphyry; then take isinglass size, what quantity you please, of the finest and best smalt a sufficient quantity, mix them well; to which add of your white lead, before ground, so much as may give it a sufficient body; mix all these together to the consistence of a paint.

BLUEING of Metals is performed by heating them in the fire, till they assume a blue colour; particularly practised by the gilders, who blue their metals before they apply the gold and silver leaf.

BLUE-BOTTLE, in botany. See *CENTAUREA*.

BLUE-MANTLE in heraldry, the title of a purfluant at arms.

BLUENESS, the quality which denominates a body blue; or it is such a size and texture of the parts which compose the surface of a body, as dispose them to reflect the blue, or azure rays of light, and those only to the eye.

BLUNDERBUSS, a short fire-arm with a wide bore, capable of holding a number of bullets at once.

BLUSHING, a suffusion, or redness of the cheeks, excited by a sense of shame, on account of a consciousness of some failing or imperfection.

BMI, in music, the third note in the modern scale. See the article *SCALE*.

BOARD, a long piece of timber, sawed thin for building and several other purposes. See the article *TIMBER*.

BOARD is also used for an office under the government. Thus we say, the board of trade and plantations, the board of works, ordnance, &c.

BOARDING, in a naval engagement, a desperate and furious assault made by one ship on another to defeat her, by entering aboard her in battle, either because the common methods of cannonading and firing musquetry had failed of success, or because she may have a greater number of men, and be better equipped for this attack than the enemy who defends herself against it.

An officer should consider well the dangerous consequences that attend boarding a ship of war, before he attempts it; and be pretty certain that his adversary is thin of men; for, perhaps, he wishes to be boarded; if so, great slaughter must ensue.

Before boarding, the officer should also judge of his own strength as well as that of the enemy; the sea must likewise be considered, lest it may run so high as to endanger both ships going to the bottom. Ships of equal force ought not to be fond of this mode of fighting, and when they do attempt it, it may be more advisable to lay the enemy's ship aboard on the lee-side, especially if there be any swell or sea, as the water is there the smoothest; besides, in laying a ship aboard to leeward, if you find too warm a reception, you can better get clear and stand off from the enemy; this appears, however, to be the only advantage of being to leeward; but as the weather-ship can, at most times, be to leeward when she pleases, it is, perhaps, more eligible to be to windward, since she will have it in her power, as she passes under the lee of her antagonist, to rake her in crossing athwart the stern, (i. e. firing her broadside in at the other's stern, so that the shot will rake the whole length of the ship, which is probably the most fatal event that can happen in a sea-engagement.) This if she can once effectually perform, she must in all likelihood conquer her adversary, and the same, if she can lay him athwart hawse, which.

which both will endeavour to avoid, if either sees the other attempt it. See **ATHWART**.

Boarding may be performed in different places of the ship according to the circumstances, preparation, and position of both; the assailant having previously selected a number of men armed with pistols and cutlasses, and occasionally provided with powder-flasks; these are slight bottles filled with gun-powder, and fitted with a fuse, which is lighted immediately before the assault: when the ships are laid close to each other, the powder-flasks are thrown amongst the crew of the ship intended to be boarded; these instantly break, are fired by the fuses, and cover the deck with horror, smoke, and confusion; add to this, that they who put this attempt in execution have generally an earthen shell suspended from their yard-arms, or bowsprit-end, called a skink-pot; this machine is likewise charged with powder, together with certain suffocating and inflammable materials, with a lighted fuse at the aperture: this also is let fall at the same time with the powder-flasks upon the deck of the defendant, and at once bursts, catches fire, and fills the deck with intolerable stench and distraction: amidst the confusion produced by this infernal apparatus, the detachment provided rush aboard, sword in hand, under cover of the smoke on their antagonist, who stands in the same situation with a citadel stormed by the besiegers, and is easily overpowered unless he has close-quarters, to where he can retreat. See **BOWSPRIT**, **CLOSE QUARTERS**. This stratagem is rarely however put in execution by his majesty's ships, which most commonly decide the battle by cannonading, and seldom grapple with their enemies: it is chiefly practised by privateers on the stoutest merchant-ships, &c.

"To prevent boarding, if the ship is boarded on the quarter, the detachment of marine forces should keep in close order, fire a volley on the enemy as they attempt to board, charge them at once with bayonets, and never give them time to get any footing.

"If the ship is boarded on the bow, or in the waist, (i. e. fore-part or middle) and it should be thought necessary to order some marines thither from the poop or quarter-deck, the front rank must face at once to the right, or left, run to the place directed, and charge the enemy in an instant; if the rear rank is wanted, the same directions are to be observed.

"When marines have been long enough at sea to get the proper use of their hands and legs, I can see no reason why they should not be employed in boarding the enemy, as well as the seamen, when such service is intended. I would therefore propose, that a marine officer should take the choice of the detachment, arm them with pistols and cutlasses, and board with them in conjunction with a sea-officer and the party of sailors: the marines, who enter voluntarily on this service, should have

some reward, be particularly respected, and recommended to be made corporals as soon as possible." The three last paragraphs we have quoted from *Mr. Macintire's Treatise on the Discipline of Marine Forces*; to which we may subjoin, that,

To prevent boarding, a high rope-netting extended by the shrouds from one end of the ship to the other, has been frequently used; and we may add, as our own opinion, that if some small taibles were ready to be hooked to the bottom of this netting, which is to hang loose over the ship's side, being then more difficult to surmount, as it swings in and out by the ship's rolling, these taibles being hooked on the outside instantly on the attempt to board, which might easily be done, and then the lower part of the netting hoisted up, while the boarders are climbing on it, would exhibit a very extraordinary and somewhat ridiculous spectacle, by entangling and suspending a swarm of the boarders, as a mark for the musquetry of the marines at their leisure.

BOAT is a small open vessel, conducted on the water by rowing or sailing. The construction, machinery, and even the names of boats are very different, according to the various purposes for which they are calculated, and the places where they are to be employed.

Thus they are occasionally sharp, or flat bottomed; slight, or strong; open, or decked; plain, or ornamented, as they may be designed for deep or shallower bottoms; for swiftness or burthen; for sailing in a harbour or at sea; and for convenience or pleasure.

The largest boat used by a ship of war is the long-boat, which is commonly furnished with a mast and sails, and can be occasionally decked, armed, and equipped, for cruising short distances against the enemy, or smugglers, or impressing of seamen, &c.

The barges are next in order, which are long, slighter, and narrower, and are employed to row admirals, and captains of men of war; these are very unfit for sea. See the article **BARGE**, in the second paragraph.

Pinnaces exactly resemble barges, only that they are somewhat smaller, and never row more than eight oars, whereas a barge properly never rows less than ten: these are for the use of the lieutenants, &c.

Cutters of a ship are broader, deeper, and shorter than the barge and pinnaces; they are fitter for sailing, and are commonly employed for carrying stores, passengers, &c. to and from the ship to which they belong. In the structure of these sort of cutters, the lower edge of every plank in the side overlays the next below it.

Yawls are something less than the cutters, nearly of the same form, and used for similar services.

The above particularly belong to men of war.

merchant-ships have seldom more than two, or three at most, viz. long-boat and yawl; they may occasionally have a small pinnace or skiff besides.

Merchant-ships which use the Mediterranean navigation, commonly have, and always ought to have a lanch in the place of a long-boat; which is longer, more flat-bottomed, and better calculated every way for the harbours of that sea than a long-boat.

Wherries are light, sharp, boats, used in a river or harbour for carrying passengers to and fro.

Punts are a sort of oblong, flat-bottomed boats, nearly resembling floating stages; they are used by shipwrights and caulkers for breaming, caulking, or repairing a ship's bottom.

A Moses is a very flat broad boat, used by merchant-ships amongst the Caribbee-Islands, to bring off hogheads of sugar from the sea-beech.

A felucca is a light boat somewhat resembling a wherry, employed in the Mediterranean for passage: the natives of Barbary also call a small cruising galley felucca.

For the larger sorts of boats, see the articles CRAFT, CUTTER, SHALLOP, PERIAGUA.

Of all the small boats, a Norway yawl seems to be the best calculated for sea, as they will often appear out on the coast of that country, when a stout ship can hardly carry any sail.

BOATSWAIN of a ship, the officer who has the boats, sails, rigging, colours, anchors, and cables committed to his charge.

It is likewise his office to summon the crew to their duty, and assist, with his mate, in relieving the watch, to see that the men attend the necessary business of the ship upon deck, and perform it with as little noise as possible.

The boatswain, partly from a perpetual bellowing, and partly from a bear-like sympathy, and savage affectation to imitate his brethren of the ratan, acquires a tone of voice so very harsh and terrible, that in the opinion of a celebrated Milefian musical doctor, this inharmonious strain very nearly resembles the braying of an ass. Indeed, it is so difficult to distinguish their voices from one another at a distance, that while two officers of different ships were lately divided in their opinions about a boatswain whom they heard not far off, each asserting him to belong to his own ship; the man actually proved to be a different person, being only a deputy, or subaltern-boatswain, who had anticipated his rank, and was already perfectly qualified in the modifying his voice to that dreadful sound.

The boatswain is moreover appointed to execute the same offices at sea which the hangman does on shore; such as scourging, or otherwise punishing offenders.

BOB, a term used for the ball of a short pendulum.

BOBBIN, a small piece of wood turned in the form of a cylinder, with a little border jutting out at each end, bored through to receive a small iron pivot. It serves to spin with the spinning-wheel, or to wind thread, worsted, hair, cotton, silk, gold, and silver.

There are bobbins of several lengths and sizes, according to the materials which are to be spun or wound. Those used by the silk dealer and the manufacturers in gold and silver, are thick short bobbins; and so are those used by the woollen manufacturers.

BOB-STAY, in the marine, a rope inserted through a ship's prow, or stem, and having both parts of it reach up, after the insertion, to the middle of the bowsprit, where the ends are spliced together, till it becomes like one of the links of a chain: after this, it is drawn extremely tight by the application of mechanical powers.

The use of the bob-stay is to draw down and keep steady the bow-sprit, and counteract the strain of the stays, which draw it upwards: the bowsprit is also fortified by shrouds on each side, which are all very necessary, as the foremast and the upper-part of the main-mast are stayed, and greatly supported by the bowsprit. See BOWSPRIT, MAST, STAY. For this reason, the bob-stay is the first stay set up, that is, drawn tight, in a ship; to perform which task more effectually, it is common to suspend a boat, or some other weighty body, at the bowsprit end to press it downwards.

BOCARDO, among the logicians, the fifth mode of the third figure of syllogisms, in which the middle proposition is an universal affirmative, and the first and last particular negatives; thus:

B o Some sickly persons are not students;

c a r Every sickly person is pale;

d o. Therefore some persons are pale that are not students.

BOCCONIA, in botany, a dodecandrious plant, whose flower consists of four narrow petals with ten short filaments; the fruit is oval, contracted on each side, long and compressed, containing a cell filled with pulp, including a single round seed. This plant is common in Jamaica and several other parts of America, where it grows to the height of ten or twelve feet, having a straight trunk as large as a man's arm, covered with a white smooth bark. At the top it divides into several branches, on which the leaves are placed alternately; these leaves are eight or nine inches long, and five or six broad, deeply sinuated, sometimes almost to the midrib, and are of a fine glaucous colour. The whole plant abounds with a yellow juice like the greatercelandine, which is of an acrid nature, so that it is used by the inhabitants of America to take off warts and spots from the eyes. It is propagated by seeds, but being very

tender, must be kept constantly in a hot-house to preserve in this climate.

BOCK-LAND, in the Saxons time, is what we now call freehold lands, held by the better sort of persons by charter or deed in writing, by which name it was distinguished from folkland, or copyhold land, holden by the common people without writing.

BODY, in philosophy, a solid, extended, palpable substance; of itself merely passive, and indifferent either to motion or rest, but capable of any sort of motion, and of all figures and forms. Body is composed, according to the Peripatetics, of matter, form, and privation; according to the Epicureans and Corpuscularians, of an assemblage of hooked heavy atoms; according to the Cartesians, of a certain quantity of extension; according to the Newtonians, of a system or association of solid, massy, hard, impenetrable, immovable particles, ranged or disposed in this or that manner; whence result bodies of this or that form, distinguished by this or that name.

That all bodies agree in one common matter, the schoolmen themselves allow; making what they call the *materia prima* to be the basis of them all; and their specific differences to spring from their particular forms: and since the true notion of body consists either alone in its extension, or in that and impenetrability together, it will follow, that the differences, which make the varieties of bodies we see, must not proceed from the nature of mere matter, of which we have but one uniform conception; but from certain attributes, such as motion, size, position, &c. which we call mechanical affections.

"We are as far, says Mr. Locke, from the idea of substance of body, by the complex idea of extended, figured, coloured, and all other sensible qualities, which is all we know of it, as if we knew nothing at all; nor after all the acquaintance and familiarity, which we imagine we have with matter, and the many qualities men assure themselves they perceive and know in bodies, will it, perhaps, upon examination, be found, that they have any more or clearer primary ideas belonging to body, than they have belonging to immaterial spirit. The primary ideas we have peculiar to body, as contradistinguished to spirit, are, the cohesion of solid, and consequently separable parts; and a power of communicating motion by impulse. These are the original ideas proper and peculiar to body; for figure is but the consequence of finite extension." After which he goes on, and clearly proves the idea of the substance of spirit and body, equally clear and known to us.

BODY, among painters, as to bear a body, a term signifying that the colours are of such a nature, as to be capable of being ground so fine, and

mixing with the oil so entirely, as to seem only a very thick oil of the same colour.

But such colours as are said not to bear a body, will readily part with the oil when laid on the work; so that when the colour shall be laid on a piece of work, there will be a separation; the colour in some parts, and the oil in others, except they are tempered extraordinary thick.

BODY, in the art of war, a number of forces, horse and foot, united and marching under one commander.

Main BODY of an Army, the troops encamped in the center between the two wings, and generally infantry; the other two bodies are the vanguard and the rear-guard: these being the three into which an army, ranged in form of battle, is divided.

BODY of Reserve. See **RESERVE**.

BODY, in *Geometry*, is that which has three dimensions; length, breadth, and thickness; and is generated by the motion of a superficies. See **SOLID**.

BOERHAVIA, in botany, a genus of monandrous plants, whose flower consists of a single campanulated petal, erect, and of a quintangular form; it hath in some species one, and in others two filaments, which are short, and topped with double globose antheræ; the germen is placed below the receptacle, supporting a short filiform style, and becomes afterward a single oblong seed. The inhabitants of the West-Indies, where these plants are natives, give them the name of hog-weed, and ascribe to them many excellent virtues. In this climate they are raised from seeds, and require a hot-house to preserve them.

BOG properly signifies a quagmire, covered indeed with grass, but not solid enough to support the weight of the body; in which sense it differs only from marshes or fens, as a part from the whole; some even restrain the term bog to quagmires pent up between two hills; whereas fens lie in champaign and low countries, where the descent is very small.

To drain boggy lands, a good method is, to make trenches of a sufficient depth to carry off the moisture; and if these are partly filled up with rough stones, and then covered with thorn-bushes and straw to keep the earth from filling up the interstices, a stratum of good earth and turf may be laid over all; the cavities among the stones will give passage to the water, and the turf will grow at top, as if nothing had been done. See the article **FEN**.

BOGOMILI, or **BOGARMITÆ**, in church history, a sect of heretics, which sprung up about the year 1179. They thought that but seven books of the Scripture are to be received; that the use of churches, of the sacrament of the Lord's supper, and all prayer, except the Lord's prayer, ought to be abolished; that the baptism of Catholics is

im-

imperfect; that the persons of the Trinity are unequal; and that they oftentimes made themselves visible to those of their sect. They said, that the devils dwelt in the churches; and that Satan had resided in the temple of Solomon from the destruction of Jerusalem to their own time.

BOIGUACU, the largest of all serpents, being from twenty-four to forty feet long, and thick in proportion. It is found in the East and West-Indies, where the Europeans, as well as the natives, are extremely fond of it as food.

BOILING, or *EVULLITION*, in physics, the agitation of a fluid body, arising from the application of fire, &c. The phenomena of boiling may be thus accounted for: the minute particles of the fuel, being detached from each other, and impelled *in orbem* with a great velocity; that is, being converted into fire, pass the pores of the containing vessel, and mix with the fluid. By the resistance they here meet, their motion is destroyed; that is, they communicate it wholly to the quiescent water: hence arises, at first, a small intestine motion in the water, and from the continued action of the first cause, the effect is increased, and the motion of the water continually accelerated; so that, by degrees, it becomes sensibly agitated: but now the particles of fire, sticking on those in the lowest surface of the water, will not only give them an impulse upwards, contrary to the laws of equilibrium, but will likewise render them specifically lighter than before, so as to determine them to ascend according to the laws of equilibrium; and this, either by inflating them into little vesicles, by the attraction of the particles of water around them, or by breaking and separating the little spherules of water, and so increasing the ratio of their surface to their solid content. There will be, therefore, a constant flux of water, from the bottom to the top of the vessel, and consequently a reciprocal flux from the top to the bottom; that is, the upper and under water will change places: and hence we have the reason of that phenomena of the water being hot at top, sooner than at bottom.

Again, an intense heat will diminish the specific gravity of water, so as not only to make it mount in water, but also in air: whence arise the phenomena of vapour and smoke, though the air, inclosed in the interstices of the water, must be allowed a good share in this appearance; for that air, being dilated, and its spring strengthened by the action of the fire, breaks its prison, and ascends through the water into the air, carrying with it of the contiguous spherules of water, so many as shall hang in its villi, or as can adhere immediately to it.

The particles of the air, in the several interstices of the fluid mass thus expanded and moving

upwards; will meet and coalesce in their passage; by which means great quantities of the water will be heaved up and let down alternately, as the air rises up, and again passes from the water; for the air, after coalition, though it may buoy up a great heap of water, by its elasticity, while in the water, yet cannot carry it up with itself into the atmosphere; since, when once got free from the upper surface of the water in the vessel, it will unbend itself in the atmosphere, and so its spring and force become just equal to that of the common unheated air: and hence we see the reason of the principal phenomena of boiling, viz. the fluctuating of the surface of the water.

The ingenious Mr. Amonton has shewn, that water heated to a degree of boiling, will not conceive any further heat, how much soever the fire be increased: yet this excellent discovery may receive a considerable improvement from what Mr. Fahrenheit has observed, viz. that the heat of the same boiling water is always regularly greater, by how much the weight of the atmosphere is greater which presses upon its surface: and again, that the same heat of the boiling water diminishes, as the weight of the incumbent atmosphere grows less. Hence, in marking the degree of heat in boiling water, it will be necessary to note the weight of the atmosphere at the same time by the barometer; otherwise no certain measure will be expressed. In the mean time, however, it must be allowed, that so long as the pressure of the atmosphere continues the same, boiling water will not grow hotter by any increase of fire whatever; and with this limitation, Mr. Amonton's rule will for ever hold true. When the difference of the weight of the atmosphere is three ounces, the greatest degree of heat in boiling water, under these different weights, will be eight or nine degrees: from whence the author evidently deduces, that by how much the particles of water are more compressed to each other, upon increasing the incumbent weight, by so much the more fire is required to make them recede from each other, wherein ebullition consists. Hence also he concluded, that a thermometer applied in boiling water, would mark, by the degree of heat it expresses, the gravity of the atmosphere at that time.

BOLES, a genus of earths, moderately coherent, ponderous, soft, and not stiff and viscid; composed of fine particles, smooth to the touch, easily breaking between the fingers, readily diffusible in water, and freely and easily subsiding from it.

BOLE *Armenic* is of a pale colour, between red and yellow, smooth and slippery to the touch, somewhat glossy, pure from sand or any perceptible gritty matter. It readily crumbles betwixt the fingers, and adheres to the tongue. Softened with
water,

water, it forms a smooth paste: diluted with a larger quantity of water, it remains for a considerable time suspended.

This earth is employed medicinally as a styptic, both internally and externally; a virtue which seems to proceed from its ferrugineous impregnation: to the anti-peffilential and alexipharmic qualities, for which it has long been celebrated, it has no pretence; and several experiments have sufficiently evinced, that the absorbent ones, which some ascribe to it, have no just foundation. It is prepared or purified by washing it over with water; the pure bole remaining suspended a considerable time, so as to be poured off with the liquor, whilst the sandy or other grosser matter remains behind: after the bole has settled from the water, it is moderately dried, formed into rolls or cakes, and afterwards further exiccated for use.

Red Bole. The common sort of this earth is coarser than the Armenian, and participates more largely of iron: hence it is never given internally, unless to cattle.

White Bole is brought to us ready washed, and formed into large rolls or cylindric globes, not of a chalky whiteness, but rather of an ash-colour. Formerly it came only from Tuscany, or the Island Elva: at present it is supplied chiefly from Norway, the Island Bornholm, or places nearer home. It differs from the two preceding in containing no manifest iron matter, and consequently in wanting their astringency. It has been recommended as an absorbent; but experiments made upon it with acids, shew that it little deserves that character, any more than the other boles. Some have a method of recovering the lustre of pearls, especially the Scotch ones, by warming them a little over the fire, and rubbing them with powdered white bole.

BOLLITO, a name by which the Italians call a sea-green colour in artificial crystal. To prepare this colour, you must have in the furnace a pot filled with forty pound of good crystal, first carefully skimmed, boiled, and purified, without any maganese: then you must have twelve ounces of the powder of small leaves of copper, thrice calcined, half an ounce of zaffer in powder: mix them together, and put them at four times into the pot, that they may the better mix with the glass, stirring them well each time of putting in the powder, for fear that it should swell too much and run over.

BOLONIAN, in general, something belonging to Bologna. Hence

BOLONIAN Stone is a sulphureous kind of stone, about the bigness of a walnut, found near Bologna; which, when duly prepared by calcination, makes a species of phosphorus. See PHOSPHORUS.

BOLSTERS, in the marine, a sort of small

cushions, or bags filled with tarred canvas, laid between the collars of the stays, and the edge of some piece of wood on which they lie; they are used to prevent the stays from being chaffed or galled by friction, as the ship rocks or pitches at sea.

BOLSTERS of a Saddle, those parts of a great saddle which are raised upon the bows, both before and behind, to hold the rider's thigh, and keep him in a right posture.

BOLT, among builders, an iron fastening fixed to doors and windows. They are generally distinguished into three kinds, viz. plate, round, and spring bolts.

BOLTS, in gunnery, are of several sorts, as 1. Transum-bolts, that go between the cheeks of a gun-carriage, to strengthen the transums. 2. Prisse-bolts, the large knobs of iron on the cheeks of a carriage, which keep the handspike from sliding, when it is poizing up the breech of a piece. 3. Traverse-bolts, the two short bolts that being put one in each end of a mortar-carriage, serve to traverse her. 4. Bracket-bolts, the bolts that go through the cheeks of a mortar, and by the help of quoins keep her fixed at the given elevation. And 5. Bed-bolts, the four bolts that fasten the brackets of a mortar to the bed.

BOLT of Canvas, in commerce, the quantity of twenty-eight ells.

BOLT-ROPE, in the marine, a rope passing all round the edges of the sails, to which they are sewed, to strengthen the sails, and prevent them from rending: those parts of it which are on the perpendicular or sloping sides, are called the leeches; that part at the bottom, the foot-rope; and if the sail be square or oblong, the upper part is called the head-rope.

BOLTERS, or **BOULTERS**, a kind of sieves for meal, having the bottoms made of woollen, hair, or even wire.

BOLTING, or **BOULTING**, the act of separating the flour from the bran, by means of a sieve or bolter.

BOLTING-MILL, a versatile engine for sifting with more ease and expedition. The cloth round this is called the boulder.

BOLUS, an extemporaneous form of a medicine, soft, coherent, a little thicker than honey, the quantity of which is a little morsel or mouthful; for which reason it is by some called buccella.

BOLZAS, a sort of ticking which comes from the East-Indies.

BOMB, in military affairs, a large orbicular shell of cast-iron, having a touch-hole, or aperture, through which a fuse is inserted, and a quantity of gun-powder pound in to charge it. The fuse of the bomb is a little kind of frustum of a cone, concave within, made of willow linden, or some

other very dry wood, filled with a composition of the best powder, sulphur, and salt-petre. The bomb being charged, this fuse is thrust in the cavity through the touch-hole, and when fired, communicates the fire to the powder with which the bomb is charged; the wood of the fuse, before it is filled, is called the *ampoulette*.

The fuses for bombs are charged with great care, that nothing may prevent their communicating the fire to the powder in the center of the bomb, to the size of which they are to be exactly proportioned; they are driven and fixed into the bomb, so that only about an inch and an half comes out beyond the touch-hole.

These bombs produce two dangerous effects, viz. that of ruining the most substantial buildings by their weight, and of creating great confusion by their splinters; for when the powder they are charged with takes fire, its effort breaks or bursts the bomb, and explodes the splinters on every side with great violence. *Le Blond. Elem. War.*

Experience shews, that fifteen pounds of powder ought to be put into a bomb of twelve inches, which weighs when charged one hundred and forty-five pounds: that a bomb of eight inches requires four pounds, weighing when charged about forty pounds; that one of six inches requires three pounds, and weighs when charged a little more than twenty-three pounds: and lastly, that thirty pounds of powder are required for a bomb of seventeen inches ten lines diameter, which weighs, when charged, about five hundred and twenty pounds. *M. Belidor Bombard. Franc.*

But later experiments prove, that the same bombs charged with a much less quantity of powder, will produce the same effect. M. Belidor himself has reduced this quantity to two pounds and a half for a bomb of twelve inches, and one pound to a bomb of eight.

It is evident that the design of the powder with which a bomb is charged, is to make it burst; and that if it bursts with a quantity of powder less than it is commonly charged with, that quantity is sufficient, and that all above is absolutely lost.

There is one particular, however, to be observed, which is, that when bombs are intended to fire the buildings on which they are thrown, the larger the charge, the better they succeed; but on all other occasions, the quantity of powder more than sufficient to burst the bomb, cannot produce any advantageous effect. See MORTAR, PROJECTILE.

The fuses of bombs are charged long before there is any occasion to use them; and that the composition they are filled with may not fall out, or spoil by growing damp or wet, the two ends are covered with a composition of tallow, mixed either with bees-wax or pitch. When the fuse is to be put into the bomb, care is taken to open the little

end, or cut it off; as to the great end, it is never opened till the bomb is in the mortar, and just going to be fired. *Le Blond. Elem. War.*

The figure A, (Plate XXI. fig. 1.) shews a bomb as it appears to the eye; the second, B, represents the section or profile, and consequently shows its thickness; the parts *d* and *e* of the bomb A, are its handles, or the parts by which it is lifted up; *e* is the touch-hole through which the powder is poured to charge it.

It appears by fig. B. that the lower part of the bomb is thickest, which is contrived that the bomb being heavier on that side, may be sure to fall upon it, and never upon the fuse *f, g*; this heavy under part is called the breech of the bomb. The diameter of a bomb ought, at least, to be five or six lines less than the bore of the mortar from which it is to be discharged.

BOMB-BATTERY. See BATTERY of Mortars.

BOMB-CHEST. See the article CAISSON.

BOMB-VESSELS, in the marine, small ships particularly calculated for throwing bombs into a fortress: they are said to be invented by M. Reyneau, and to have been first put in action at the bombardment of Algiers; till then, it had been judged impracticable to bombard a place from the sea. See the article BOMB-KETCH.

BOMBARD, a piece of ordnance, antiently in use, very short and thick, with an extreme large bore. There have been bombards which have thrown a ball of three hundred weight: they made use of cranes to load them. There are still some of these in use amongst the Turks.

BOMBARDIER, the person employed in charging the bomb, fixing and driving in the fuse, and loading and firing the mortar, under the direction of the engineers: he is also employed in other military fire-works.

BOMBARDING, the act of assaulting a city or fortress, by throwing bombs into it, in order to set fire to, and ruin the houses, magazines, &c. and to do other mischief.

As one of the effects of the bomb results from its weight, it is never discharged as a ball from a cannon, that is, by pointing or directing it at a certain object; but the mortar is a little inclined from the horizon, so that the bomb being thrown up obliquely, much in the same direction as a tennis-ball struck by the racket, may fall upon the place intended; from whence it appears, that a mortar has no point-blank range, or at least that no use is made of it. See MORTAR, PROJECTILE, RANGE.

If the fuse sets fire to the bomb before it falls on the place intended, the bomb will burst in the air, and may do as much mischief amongst those who fired the mortar, as those against whom it was discharged. To prevent this inconvenience it is so contrived, that the fuse (the time of its burning out being pretty exactly known) shall not fire the bomb

bomb, till the moment of its fall on the place against which it is thrown. To effect this (as the fufe will last, at least, as long as the bomb is in going its greatest possible range) when a bomb is thrown to a great distance, the fufe and the mortars are fired at the same time, and when the bomb has not far to go, part of the fufe is suffered to burn out before the mortar is discharged.

BOMBARDO, a musical instrument of the wind kind, much the same as the bassoon, and used as a bass to the hautboy.

BOMBASINE, in commerce, a kind of silk-stuff manufactured at Milan, and thence sent into France and other countries.

BOMBAST, in matters of literature, a high style made up of hard words, with little meaning, and less sense.

BOMBAX, in botany, a genus of trees which are natives of the West-Indies; they generally grow with very straight stems, and arrive to a great magnitude, being some of the tallest trees in those countries. They seldom put out any side branches till they arrive to a considerable height; the branches towards the top are furnished with leaves, composed of five, seven, or nine oblong smooth little leaves, which are spear-shaped, and join to one center at their base, where they adhere to a long foot-stalk: these fall off every year, so that for some time the trees are naked, and before the new leaves come out, the flower-buds appear at the end of the branches, and soon after the flowers expand, which are composed of five oblong purple petals, with a great many subulated stamina in the center. When these decay, they are succeeded by large oval fruit, having a thick ligneous cover, which when ripe opens in five parts, and is full of a dark short cotton, inclosing many roundish seeds. The down which is inclosed in these seed-vessels is seldom used, except by the poorer inhabitants to stuff pillows or chairs. The wood is very light, but not much valued, except for making canoes, which is the chief use made of it.

BOMBUS, in medicine, a resounding and ringing noise in the ear, which is accounted by Hippocrates a mortal symptom in acute diseases.

BOMBYLIUS, in natural history, the name of the common humble-bee, of which we have a great variety of species, many of them very beautiful.

BOMBYLOPHAGES, in the history of insects, humble-bee-eater, the name of a fly of the tipula kind, which is larger and stronger than the common kinds; and loving honey, without knowing how to extract it from the flowers, it seizes on the humble-bees, and destroys them, in order to get the bag of honey which they contain. It is of a blackish colour in the body; its head is of a bright red, and the eyes very large and prominent. It is chiefly found in mountainous places.

BOMONICI, in Grecian antiquity, young men

of Lacedæmon, who contended at the sacrifices of Diana, which of them was able to endure most labours; being scourged before the altar of this goddess.

BONA-FIDES, or **BONA-FIDE**, among lawyers, is as much as to say, such a thing was done really, without either fraud or deceit.

BONA-MOBILIA, the some with moveable goods or effects.

BONA-NOTABILIA, are such goods as a person dying has in another diocese than that wherein he dies, amounting to the value of five pounds at least: in which case the will of the deceased must be proved, or administration granted in the court of the archbishop of the province, unless by composition, or custom, any dioceses are authorized to do it, when rated at a greater sum.

BONA-PATRIA, an affize of countrymen, or good neighbours, where twelve or more are chosen out of the country to pass upon an affize, being sworn judicially in the presence of the party.

BONANA, in botany, a genus of plants, otherwise called musa. See *MUSA*.

BONASUS, in zoology, a species of wild ox, very thick and bulky, and furnished with a mane like a horse.

BOND, a deed, by which a person obliges himself to perform certain acts; such as to pay a certain sum, or to answer for another, or to serve an apprenticeship with a master.

In England, a bond is a deed or obligatory instrument in writing, whereby a person binds himself to another, to pay a sum of money, or to do some other act, as to make a release, surrender an estate, for quiet enjoyment; to stand to an award, save harmless, perform a will, &c. It contains an obligation with a penalty annexed, and a condition which expressly mentions what money is to be paid, or what other things are to be performed, and the limited time for the performance thereof, for which the obligation is peremptorily binding.

It may be made upon parchment or paper, though it is usually on paper, and be either in the first or third person: and the condition may be either in the same deed or in another; and sometimes indorsed upon the obligation; but it is commonly at the foot of the obligation.

BONE, in anatomy, a hard, brittle, insensible part of the body, affording form and support to the whole machine.

BONIS NON AMOVENDIS, in law, is a writ directed to the sheriffs of London, &c. charging them, that a person against whom judgment is obtained, and prosecuting a writ of error, be not suffered to remove his goods until the error is determined.

BONITO, a beautiful sea-fish of the tunny-kind; it has a long, broad, and thick body, al-

most

most free from scales, large eyes and gills, with a broad, gold-coloured streak running along the middle of each side from the gills to the tail; it is of a greenish colour on the back and sides; of a silvery whiteness, and very bright on the belly: there are vast shoals of these fish in many parts of the Atlantic-ocean.

BONNET, in the marine, an additional part to be occasionally laced on, or fastened to, the bottom of certain sails in gentle breezes of wind, and taken off again when the size of the sail is to be reduced in fresher gales or storms.

BONNET, in fortification, is a small work raised beyond the counterscarp, having two faces which form a salient angle, and as it were a small ravelin without any trench. The height of this fortification is commonly three feet, and is environed with a double row of palisades, ten or twelve paces from each other. It has likewise a parapet three feet high, and is like a little advanced corps de gard.

BONNET A'PRETRE, or *Priest's BONNET*, in fortification, is an out-work, having at the head three salient angles, and two inwards; and differs from the double tenaille in this, that its sides, instead of being parallel, are like a swallow's tail, that is, narrowing or drawing close at the gorge, and opening at the head.

BONNY, in mineralogy, a name given by our miners to a bed of ore found in many places in hills, not forming a vein, nor communicating with any other vein, nor terminating in strings, as the true veins do. It is a bed of ore of five or six fathom deep, and two, or somewhat less than that, in thickness, in the largest fort; but there are smaller, to those of a foot long. They have their trains of flint-stones from them, and often deceive the miners with the expectation of a rich lead vein. They differ from the squats only in being round beds of ore, whereas the squats are flat. See **SQUAT**.

BONZES, Indian priests, who, in order to distinguish themselves from the laity, wear a chaplet round their necks, consisting of an hundred beads, and carry a staff, at the end of which is a wooden bird; they live upon the alms of the people, and yet are very charitably disposed, maintaining several orphans and widows out of their own collections. The Tonquinese have a pagod, or temple, in each town, and every pagod has at least two bonzes belonging to it; some have thirty or forty. The bonzes of China are the priests of the Fohists, or sects of Fohi; and it is one of their established tenets, that there are rewards allotted for the righteous, and punishments for the wicked, in the other world; and that there are various mansions, in which the souls of men will reside, according to their different degrees of merit. The bonzes of

Pegu are, generally, gentlemen of the highest extraction.

BOOBY, a heavy stupid bird, something resembling a gull, or sea-mew, common about Hispaniola, Jamaica, or Cuba. It is furnished with so small a portion of the sagacity which dictates self-preservation to almost all the feathered tribe, that it will suffer any body to take it in the evening or night, when it lights on a ship in her passage; and will neither, on this occasion, resist, or attempt to escape, but make a continual clamour: it generally lives upon fish.

BOOK, *Liber*, the composition of a man of wit or learning, designed to communicate somewhat he has invented, experienced, or collected, to the public, and thence to posterity; being withheld of a competent length to make a volume.

In this sense, a book is distinguished from a pamphlet, by its greater length; and from a tome, or volume, by its containing the whole writing. According to the ancients, a book differed from an epistle, not only in bulk, but in that the latter was folded, and the former rolled up; not but that there are divers ancient books now extant, under the name of epistles.

Origin of Books.—We have nothing that is clear on that subject. The books of Moses are doubtless the oldest books now extant; but there were books before those of Moses, since he cites several. Scipio Sgambati, and others, even talk of books before the Deluge, written by the patriarchs Adam, Seth, Enos, Cainan, Enoch, Methuselah, Lamech, Noah and his wife; also by Ham, Japhet and his wife; besides others, by demons or angels; of all which some moderns have found enough to fill an Antediluvian library: but they appear all either the dreams of idle writers, or the impostures of fraudulent ones. A book of Enoch is even cited in the Epistle of Jude, ver. 10. and 15. from which some endeavour to prove the reality of the Antediluvian writings; but the book cited by that apostle is generally allowed, both by ancient and modern writers, to be spurious.

Of profane books, the oldest extant are Homer's poems, which were so even in the time of Sixtus Empiricus; though we find mention in Greek writers of several others prior to Homer, as Hermes, Orpheus, Daphne, Horus, Linus, Musæus, Palamedes, Zoroaster, &c. but of the greater part of these there is not the least fragment remaining; and of others, the pieces which go under their names are generally held, by the learned, to be supposititious. F. Hardouin goes farther, charging all the ancient books, both Greek and Latin, except Cicero, Pliny, Virgil's Georgics, Horace's Satires and Epistles, Herodotus, and Homer, to be spurious, and forged in the XIIIth century, by a club of persons, under the direction of one Severus Archontius. Among the

the Greeks, it is to be observed, the oldest books were in verse, which was prior to prose. Herodotus's history is the oldest book extant of the profane kind.

Materials of Books.—Several sorts of materials were used formerly in making books: plates of lead and copper, the bark of trees, bricks, stone, and wood, were the first materials employed to engrave such things upon, as men were willing to have transmitted to posterity. Josephus speaks of two columns, the one of stone, the other of brick, on which the children of Seth wrote their inventions and astronomical discoveries. Porphyry makes mention of some pillars, preserved in Crete, on which the ceremonies practised by the Corybantes in their sacrifices, were recorded. Hesiod's works were originally written upon tables of lead, and deposited in the temple of the Muses, in Boeotia. The ten commandments, delivered to Moses, were written upon stone; and Solon's laws upon wooden planks. Tables of wood, box, and ivory, were common among the ancients: when of wood, they were frequently covered with wax, that people might write on them with more ease, or blot out what they had written. The leaves of the palm-tree were afterwards used instead of wooden planks, and the finest and thinnest part of the bark of such trees, as the lime, the ash, the maple, and the elm; from hence comes the word *liber*, which signifies the inner bark of trees; and as these barks were rolled up, in order to be removed with greater ease, these rolls were called *volumen*, a volume; a name afterwards given to the like rolls of paper, or parchment.

Thus we find books were first written on stones, witness the Decalogue given to Moses: then on the parts of plants, as leaves chiefly of the palm-tree; the rind and barks, especially of the tilia, or phillyrea, and the Egyptian papyrus. By degrees wax, then leather, were introduced, especially the skins of goats and sheep, of which at length parchment was prepared: then lead came into use; also linen, silk, horn, and lastly, paper itself.

Form of Books.—The first books were in the form of blocks and tables: but as flexible matter came to be wrote upon, they found it more convenient to make their books in the form of rolls: these were composed of several sheets, fastened to each other, and rolled upon a stick, or umbilicus; the whole making a kind of column, or cylinder, which was to be managed by the umbilicus as a handle, it being reputed a crime to take hold of the roll itself: the outside of the volume was called *frons*; the ends of the umbilicus, *cornua*, horns, which were usually carved, and adorned with silver, ivory, or even gold and precious stones: the title, *σύλλαβος*, was struck on the outside; the whole volume when extended, might make a yard and a half wide, and fifty long. The form which obtains a-

mong us is the square, composed of several leaves; which was also known, though little used, by the ancients.

To the form of books belongs also the internal economy, as the order and arrangement of points and letters into lines and pages, with margins and other appurtenants. This has undergone many varieties; at first the letters were only divided into lines, then into separate words, which, by degrees, were noted with accents, and distributed, by points and stops, into periods, paragraphs, chapters, and other divisions. In some countries, as among the Orientals, the lines began from the right, and ran towards the left; in others, as the northern and western nations, from left to right; others, as the Greeks, followed both directions, alternately going in the one, and returning in the other, called *boustrophedon*: in most countries the lines run from one side to the other: in some, particularly the Chinese, from top to bottom. Again, in some the page is entire and uniform; in others, divided into columns; in others, distinguished into texts and notes, either marginal, or at the bottom; usually it is furnished with signatures and catch-words; sometimes also with a register, to discover whether the book is complete. To these are added the apparatus of summaries, or side notes, the embellishments of red, gold, or initial letters, head-pieces, tail-pieces, effigies, schemes, maps, and the like. The end of the book, now denoted by *FINIS*, was anciently marked with this character <, called *cornis*: there also occur certain formulas at the beginnings and endings of books; the one to exhort the reader to be courageous, and proceed to the following books; the others were conclusions, often guarded with imprecations against such as should falsify them.

BOOK-BINDING is the art of gathering and fastening together the sheets of a book, and covering it with a back.

The antient art of binding of books, when first the several sheets of writings of authors were collected together, was not attended with great difficulties; for the leaves were only glued together, and rolled on round pieces or cylinders of wood; which manner of book-binding, whose invention is attributed to the Egyptians, was continued till long after the age of Augustus, and is still retained by the Jewish synagogues, where they continue to write the books of the law on vellums sewed together, making, as it were, only one long page, with two rollers, having clasps of gold or silver at their extremities, the whole book being wrapped up in a piece of silk, which serves as a cover to it.

But as this manner of binding books is attended with many inconveniencies, one of the Attalids, kings of Pergamus, invented the form now in use, of square binding, or of sewing several quires one

over another, as more commodious to the reader, who can open and shut his book in an instant, without the least difficulty, and without the leaves being exposed to wear out so soon as when rolled up, especially of books written or printed on paper. It is performed in the following manner :

The leaves are first folded with a thin piece of ivory called a folding-stick, and laid over each other in the order of the signatures ; then beaten on a stone with a hammer to make them smooth and open well, and afterwards pressed. They are then sewed upon bands, which are pieces of cord or packthread, six bands to a folio-book, five to a quarto, &c. which is done by drawing a thread through the middle of each sheet, and giving it a turn round each band, beginning with the first, and proceeding to the last.

The French book-binders apply a sheet of parchment the length of the book, on the inside of each pasteboard, so, however, as that, being cut or indented in the places against the bands, it comes out between the edge of the paste-board and the leaves of the book, to cover the back ; they call this indorsing, and they are obliged to do it, on the penalty of thirty livres, and the re-binding of the book. It is done in the press, where the back being grated with an iron instrument, with teeth to make the paste-board hold, wherewith the parchment is first fastened, they afterwards add strong glue to fortify it. After this the books are glued, and the bands opened and scraped for the better fixing the paste-boards ; the back is turned with a hammer, and the book fixed in a press between two boards, called backing-boards, in order for making a groove for fixing the paste-boards ; which being applied, holes are made for fixing them to the book, which is pressed a third time : then the book is put at last to the cutting-press, betwixt two boards, the one lying even with the press, for the knife to run upon ; the other above it, for the knife to cut against ; after which the paste-boards are squared with a pair of shears.

The next operation is sprinkling the leaves of the book, which is done by dipping a brush made of hog's bristles into vermilion and sap-green, holding the brush in one hand, and spreading the hair with the other ; by which motion the edges of the leaves are sprinkled in a regular manner, without any spots being bigger than the others, at least so far as to be disagreeable to the eye.

Then remain the covers, which are either of calf-skin, or sheep-skin. Anciently books were always bound in parchment, and most of our valuable books, even since the invention of printing, have no other binding ; but this practice has been long disused. The best binding at present is in calf.

The calf or sheep-skin, being moistened in water, is cut out to the size of the book with a knife,

then smeared over with paste, made of wheat flour, and afterwards stretched over the paste-board on the out-side ; and doubled over the edges within-side, after having first taken off the four angles, and indented and plaited it at the head-band ; which done, the book is corded or bound firmly between two bands, with a kind of whipcord, to make the cover stick the stronger to the paste-board and the back, as also to form the bands or nerves more accurately ; then set to dry, and when dry, uncorded, and the leaves at each end opened. Afterwards, the book is washed over with a little paste and water, and then sprinkled fine with a brush, by striking it either against the hand, or a stick, unless it should be marbled ; for then the spots are to be made larger, by mixing the ink with vitriol. Then the cover is glazed twice with the white of an egg beaten, as painters do their pictures when they are finished, and at last polished with a polishing-iron passed hot over the glazed cover.

Thus the binding of a book, properly so called, is finished, unless it should be lettered ; for then a piece of red Morocco is pasted on the back, between the first and second bands, to receive the title in gold letters, and sometimes a second betwixt the next bands underneath, to receive the number of the volume. In France, they seldom bind any book without both, if the work consists of several volumes ; which done, the book-binder sends his books to the gilder, which in that kingdom is a profession apart, or separate from book-binding.

The gilder makes the letters on the back, and the roses, stars, &c. between the bands, with punchcons engraven in relievio, which they press flat down, and the lines, embroideries, &c. with little cylinders of brads, rolled along by an iron roller, by means of a double branch ; in the middle whereof they are fitted on an iron stay, or axis, that passes the middle of their diameter. Before they apply any of these tools, they glaze those parts of the leather whereon they are to be applied, lightly over with a pencil, or sponge ; and when half dry, lay over them pieces of leaf gold, cut out near the size ; and on these stamp the punchcons, which are beat down with a mallet, or hammer, if the figures be large, and require a great relievio, as arms, &c. or roll the cylinders, both the one and the other, reasonably hot. The gilding thus finished, they rub off the superfluous gold with a hare's foot, leaving nothing covered with gold, but the places whereon the hot tools have left their impressions.

BOOK-KEEPING, commonly called merchants accounts, is the art or method of disposing a man's dealings or transactions in such a manner as will enable him to discern by his books the true state of his affairs, not only in respect of what is due to and from himself, but also the quantity of every par-

particular kind of goods he has in his ware-höuse, either on his own account or for others, together with the particulars of the purchase or disposal, gain or loss, attending each separate species.

There are three principal books for conducting this useful invention, viz. a Waste-Book, Journal, and Ledger, which are absolutely necessary. Besides these, there are other subsidiary books, such as the Letter-Book, Ship's-Book, Receipt-Book, Bill-Book, Invoice-Book, Sales-Book, Book of Accounts Current, Warehouse-Book, Book of Expences, and the Cash-Book; but these subservient or auxiliary books are more or less in number according to the nature of the trade, quantity of business, or method of keeping the accounts; and he is reckoned the most expert accomptant, who makes use of the fewest auxiliary books.

The Waste-Book contains all the transactions which are done every day, which ought to be set down, together with all the particulars relating thereto, in a plain, easy, and familiar stile, serving only to give a description of the affair that hath been negotiated, just in the manner it happened, and according to the time they succeed each other; and it is the foundation on which both the Journal and Ledger depend, or from which they are erected.

This book opens with an inventory of the merchant's ready money and effects, the debts due to him, and what he owes to others; after which follows a minute and accurate record of every transaction, with all the necessary circumstances of date, sums, conditions, quantity, quality, price, and every other particular, that may help to render the entries satisfactory to the present and all succeeding book-keepers. Upon this book you may observe four lines are drawn (as in the following examples) through the length of it; three of which, namely, those on the right-hand side of the leaf, are put to serve for columns in which the pounds, shillings, and pence, relating to the article transacted is to be writ down; and the other column at the left-hand and in the margin, serves for the putting a mark therein, to signify that the said article is journalized, or posted from thence into the Journal; it is usually thus *v.* The following is an example of opening a Waste-Book, and the manner of writing the transactions of the day.

W A S T E - B O O K.

London, January 1, 1765.

An INVENTORY of the Money, Goods, Debts, &c. belonging to me JAMES HENDY, taken this Day, viz.			
	£.	s.	d.
In ready money - - - - -	500	00	00
7 Pipes of red-port, at 25l. per pipe -	178	10	00
J. Hammond owes me a note on demand	200	00	00
<i>I owe as follows:</i>			
To Phil. Hendy, per note due the 9th instant - - - - -	100	00	00

London, January 3, 1765.

BOUGHT of James Hervey, 3 pipes of Malaga wine, at 25l. 10s. per pipe, for which I paid - - -	£.	s.	d.
6	76	10	00
SOLD Joseph Berwick, a piece of broad-cloth, upon trust, for - -	16	10	00
9			
PAID Phil. Hendy in full - - -	100	00	00

The Journal is a kind of preparatory for the Ledger; for it is in this book that all transactions recorded in the Waste-Book are digested, their proper Debtors and Creditors ascertained; it is also of excellent use, both to prevent errors in the Ledger, and to correct them when made; for without it the balancing a set of books, in case of any mistake, would be extremely difficult and tedious.

Upon this book you must draw five lines, (as in the following examples) three of which, namely, those on the right-side of the leaf, are put to serve for columns in which the pounds, shillings, and pence, relating to the article transacted are to be writ; in like manner as upon the Waste-Book; and the other column at the left-hand serves to set down the folios of the Ledger on which all the accounts that are laid in the Journal to be Debtors and Creditors stand: the folio of that account which is Debtor being always uppermost, and that of the Creditor under it, parted one from the other by a line in form of a vulgar fraction, thus $\frac{1}{2}$. It must also be remarked, that the titles of the several accounts in the Journal which are made Debtors and Creditors, in entering transactions of affairs therein, must be wrote in characters larger than any of the rest of the writing relating to it, and contained in one line if practicable. Under this line you must express the reason why such a person, account, or design, is made debtor, with the particular conditions of the negotiation; likewise the weight, measure, &c. of each particular parcel, or package, which is received in, or delivered out, at the price agreed upon, with the sum total in the money columns. In those entries where there are sundry Debtors to one Creditor, or several Creditors to one Debtor, the several Debtors, or Creditors, are entered in the first line, after the date, under the title of Sundries, or Sundry Accounts, and each particular Debtor and Creditor afterwards expressed below, with the respective sums short-carried.

The greatest difficulty that chiefly arises to young students in the art of book-keeping, is finding the proper Debtor and Creditor to each article in the Waste-Book, or more properly to Journalize. The authors that have lately written on this subject, have given such a multiplicity of rules, that we apprehend they rather hinder, perplex, and puzzle, than facilitate or explain this point; nor do we think there is occasion for any other rule than

what Mr. Webſter has given, viz. "That what-
ever we receive, or the perſon receiving is Debtor,
"or whatever you deliver, or the perſon delivering
"is Creditor." Whatever money, goods, and
debts, a merchant is poſſeſſed of, compoſe his
ſtock, which in order to diſpoſe properly for trade,
each ſeparate article muſt at the beginning be
charged Debtor to Stock; as on the other hand,
Stock muſt be made Debtor to the ſeveral perſons
to whom you are indebted. The following ex-
ample, which is taken from the foregoing example
of the Waſte-Book, will illuſtrate the above
rule.

JOURNAL.

London, January 1, 1765.				
SUNDRIES Dr. to STOCK.				
	£.	s.	d.	
$\frac{2}{1}$ Caſh in ready money - -	500	00	00	
$\frac{1}{1}$ Red-port, for 7 pipes at } 25l. 10s. per pipe - }	178	10	00	
$\frac{4}{1}$ James Hammond owes } per note on demand }	200	00	00	
				878 10 00
STOCK Dr. to SUNDRIES.				
$\frac{1}{1}$ To Phil. Hendy, due per note - -	100	00	00	
				3
MALAGA WINE Dr. to CASH 76l. 10s.

JOSEPH BERWICK Dr. to BROAD- CLOTH, 16l. 10s.				
$\frac{6}{3}$ Sold him one piece upon truſt - -	16	10	00	
				9
PHIL. HENDY Dr. to CASH 100l.				
$\frac{1}{2}$ Paid him in full - - - - -	100	00	00	

The Ledger is the grand and principal book of
accounts, wherein the ſeveral articles belonging to
the ſame ſubject, are collected together, and ranged
in their natural order of Debtor and Creditor, on
the oppoſite ſides of their reſpective accounts.
When this book is duly poſted, the various tran-
ſactions and dealings of a merchant with reſpect to
men, money, and merchandize, are ſo regulated
and diſpoſed under their proper heads, that they
afford a comprehensive view of all his negotiations,
from which a compleat balance of his traffic being
made, he may at any time ſee the true ſtate of each
branch of his buſineſs, and know the amount of
his preſent ſtock, or what he is worth at that time.

Upon this book you may obſerve, as in the fol-
lowing example, that there are two leaves of paper
allowed for each account, facing each other: like-
wiſe that the title of the account with the letters
Dr. are wrote on the left-hand leaf or folio in large
characters; and the words PER CONTRA, with the
letters Cr. in the ſame manner on the right-hand leaf.

You muſt likewiſe obſerve, that on each of the
leaves of every account, there are fix lines ruled
or drawn at length, four of which are on the right
hand of each leaf, and two on the left, forming as
many columns. The three columns to the right-
hand are for the pounds, ſhillings, and pence,
and the fourth for the folio. The two columns to
the left-hand are one for the year and month, and
the other for the day of the month. Beſide which
ſome draw, or make another column to the left,
for references to the Journal page; and others to
the right, for the quantity and weight of goods,
foreign money, &c. as the nature of the account
requires.

See the following example of the article Malaga
wine, in the foregoing Journal, poſted.

THE LEDGER.

1765.						PER CONTRA Cr.			
Jan ^y . 3	MALAGA WINE Dr.								
	To Caſh, at 25l. 10s. for }								
	3 pipes - - - - - }	2	76	10 00					

The firſt thing to be done in poſting or tranſ-
ferring accounts from the Journal to the Ledger, is
to title the Ledger; that is to write it in a large
fair hand, at the top of the folio, and at ſuch diſ-
tances below as your judgment ſhall direct, the
ſeveral names contained in the firſt lines of your

Journal entries, except where the word Sundries is
mentioned, when, inſtead of which, thoſe names
at the beginning of the ſubſequent lines are to be
wrote, taking care not to make two titles alike,
which may be avoided by keeping an alphabet of
the different accounts, with the folios on which
they

they are entered in the Ledger, and having frequent recourse to that.

Secondly, as all entries in the Ledger are double, you must be careful never to make a Debtor without a Creditor; that is, as in the foregoing example, if Malaga Wine be Debtor to Cash, Cash must be Creditor to Malaga Wine. Or if any other account be Debtor to Sundries, which signifies two or more particulars, those several accounts must each separately be made Creditors for the sum which that particular account was Debtor.

The method of transposing accounts from one folio of the Ledger to another; how to prove the truth of your posting by a trial balance; the method of examining the book, and correcting the errors; how the real balance is drawn out, and a new set of books opened from it, &c. take as given in a treatise on this subject, by Mr. John Cook, master of the academy in Charles-street, St. James's-square, viz.

“The method of transposing Accounts from one folio in the Ledger to another.

“If at any time the space allotted for an Account should be so filled with articles as to make it necessary to remove it to another folio in the Ledger, it may be done by one or other of the following methods, viz.

“1st. If it be an Account, where the difference between the Debtor and Creditor, with respect to money, is only considered, as is the case in all Accounts of Persons, Cash, Profit and Loss, &c. add up both sides, and make the new Account Debtor to the old, for the Balance or difference, if the Debtor side be heaviest; but, if the Creditor side be heaviest, make the old Account Debtor to the new.

“2ndly, If it be an Account of Goods, &c. add up the sides, and make the new Account Debtor to the old, for the whole quantity and price of the Goods bought; and the old Account Debtor to the new, for the total quantity and price of those sold; by which means the old Account will be balanced, and on the new one will appear both the quantity of goods bought, with the sum paid for them, and those which have been sold, with the money received, as was before on the old Account.

“How to prove the truth of your Postings, by making a Trial balance.

“The way to make a Trial balance is, to add up all the money on the Debtor sides, throughout the whole Ledger, into one sum, and all on the Creditor sides into another; if both totals come alike, you may conclude your Posting is right; for, as I have already observed, every entry in the Ledger is double, that is, no account is ever charged Debtor, but some other is, or ought to be, Credited with the like sum, by which it is plain, there are just as many Creditors as there

are Debtors; and consequently (if the accounts have been properly posted) both sides must exactly agree.

“The method of examining the books and correcting errors.

“If upon making the Balance above-mentioned, there should be a disagreement in the totals, you may then reasonably conclude (provided no mistake is made in the adding) that you have omitted either the Debtor or Creditor, or charged them with different sums, or else entered some parcel in both accounts, either on the Debtor or Creditor side, any of which errors will be discovered by pricking over your Ledger; that is, beginning at the first account, which is Stock Debtor to Cash, and against the sum make a dot thus (.), then turn to the Creditor folio, and mark that in like manner, proceeding thus with every entry throughout the book; and having by this means discovered the mistake, rectify it by one of the following methods, viz.

“If the Debtor or Creditor is omitted, it is corrected by charging which ever of them is in its proper account.

“If the Debtor or Creditor be charged with different sums, it is rectified (if either of them be charged too much) by making the opposite side Debtor to, or Creditor by error for the excess; if too little, by charging it again Debtor to, or Creditor by its counterpart for the deficiency.

“When a parcel is entered in both accounts on the same side, it is adjusted, by making the opposite side Debtor to, or Creditor by error, for the sum of the article wrong placed; then, enter the article in its proper place, by which means the mistake will be balanced, and the Account left properly stated. After this manner are all errors in Book-keeping corrected, and not by cancelling or erasing, which Merchants never admit of.

“How the real Balance is drawn out, and a new set of books opened from it.

“Balancing the Ledger, is adding up the Debtor and Creditor sides of the several accounts separately; the difference of which being posted on the defective, or lightest side, will make both even; and, consequently, the account become balanced. In doing which the following rules must be observed.

“In the first place, erect in the Ledger an account of Balance, to which the difference between the Debtors and Creditors in the account of Cash, and also in accounts of men, together with the quantity and prime costs of all goods remaining in your hands, must be carried; as for example. Let it be supposed, that the Debtor side of Cash contains 15,000l. and the Creditor 10,000l. the difference then being 5000l. (which is the money you have by you) it must be entered on the Creditor side, in order to balance the account, by making

Cash creditor by Balance 5000l. and consequently, Balance will stand Debtor to Cash 5000l. So in the Accounts of men, if the Debtor be the heaviest, the difference is the money due to you; which, in order to make the account even, must be brought on the Creditor side; therefore Balance will again be charged Debtor for the like sum, and *vice versa*. I have already mentioned, that whatever goods remain unfold are carried to Balance; but, as Accounts of goods admit of three varieties, I shall treat of each separately.

“The first then is, when none are sold.

“In this case, the Account is made even, by being Credited by Balance, for the whole quantity at prime cost.

“The second is, when all are sold.

“In which case the Account is balanced by Profit and Loss only, by being charged Debtor to, or Creditor, by that account, for the gain or loss arising from the sale of the goods.

“The third is, when only part of the Goods are sold.

“And here, both the accounts of Balance and Profit and Loss are concerned; for, in the first place, the Goods must be Credited by Balance, for those remaining at prime cost; and afterwards made Debtor to, or Creditor by Profit and Loss, for the Gain or Loss on those that are sold.

“The other accounts, such as Charges of merchandize, House-expences, &c. as they are disbursements from which no return can be expected; are all balanced by Profit and Loss, which, together with Stock and Balance, stand open till the last; and, in order to Balance them, begin with Profit and Loss, and make it Debtor to, or Creditor by Stock, for the difference of the sides, which is your whole Gain or Loss by trade; then add up the account of Stock, and close it by carrying the difference, which is your neat estate, to Balance; by which means the said account of Balance will become evened; the Debtor side of which will present you with a distinct account of all the Money, Goods, and Debts you are possessed of; and the Creditor side with an account of whatever is due from you to others; and consequently, contains, or rather is, an inventory of your effects, with which a new set of books are opened; for the better understanding of which, compare the Balance of the first set with the Inventory of the second.

“I shall now in the last place examine the methods made use of in keeping Company accounts.

“There is no part of Book-keeping that admits of greater variety, or is so extensively useful, as that which is called Company accounts, there being few Merchants, who have any considerable dealings, but what are concerned in Partnership;

notwithstanding which, it has been treated of by the majority of writers upon this subject, in the most superficial manner, and they are still divided in the method of Journalizing those cases relating to Goods in company being sold upon trust; some chusing to make the buyer Debtor to the Goods in company; and then the Partner's account company Debtor to his account current, for his half share of the money due; by which method, it is evident, your Partner's account current (which is what should particularly shew the money due, either from, or to the person) becomes Credited for a sum you, at present, do not owe him, by reason of your not having received it; and, if never paid, are not accountable for. There is also another obvious objection, which naturally arises to this method: and that is, when Goods are paid for at different times, in order to know what money is due to your Partner, recourse must be had to the Purchaser's account; and if sold, for part money, part time, both the Goods in company, and Purchaser's account, must be referred to, as it is impossible, amidst a multiplicity of business, to charge the memory with things of this nature, neither would it be proper so to do.

“By the other method made use of (which is that I shall pursue), all the above objections are removed; for as here no notice is taken of money due to your Partner, till such time as it is received, the Account company will remain open; and, as the payments are made, be charged Debtor to the current for your partner's share of the sum, by which means he will be Credited for his part of whatever money has been received; and consequently, his Account current will plainly shew what he has a right to demand of you. If any object, that, when the Goods are sold, the account company, as it shews your partner's share in them, ought to be closed; I answer: the Goods in company is the proper account to have recourse to for their disposal, that the Account company then answers the purpose of an Account at time, and may be balanced in the same manner, as it shews what money is due at Time to your Partner.”

BOOKSELLER, one who trades in books, whether he prints them himself, or gives them to be printed by others.

BOOM, in the fortification of a harbour, a strong chain or cable, on which are fastened a number of poles, &c. extending athwart the entrance of an harbour or river, to prevent the enemies ships of war from coming in: it may occasionally be sunk, or drawn up to the surface of the water, by capsterns and other mechanical powers.

Captain Park, in his *Defensive War by Sea*, published anno 1704, will furnish the reader, who is curious to understand the construction of these machines, with a particular account of their being

being prepared and fixed, which is also quoted into the Seaman's Vade-Mecum; but as they have not been much used of late, we shall say no more of them ourselves, and far less exhaust our reader's patience with so clumsy and laborious a detail.

Booms, in the marine, long poles run out from different places in a ship, to extend the bottom of certain sails: of these there are several sorts, as the jib-boom, studding-sail booms, main-boom, and square-sail boom; these two last are only appropriated to small vessels.

Boom is likewise a general name for all masts and yards.

BOOPHTHALMUS, a kind of agate with large circles in it, bearing some resemblance to an ox's eye, from whence it has got this name.

BOÖT, a well-known cover for the leg, made of leather.

BOOT-TREE, or BOOT-LAST, an instrument used by shoe-makers to widen the leg of a boot. It is a wooden cylinder slit into two parts, between which, when it is put into the boot, they drive by main force a wedge or quoin.

BOOT-TOPPING, in the marine. When either from the want of a dock, or other convenient situation, or through the hurry of her voyage, a ship cannot get her whole bottom properly trimmed and cleansed of the filth which adheres to it in the course of a sea-voyage; they usually make her lean or heel first to one side, and then to the other, as much as they may do it without danger of overturning her, in order to scrub off the grass, slime, shells, or other excrement; which having performed, they cover all that part of the bottom which is elevated above the surface of the water on one side, as the ship heels, with a mass of sulphur, tallow, and other materials, and afterwards perform the same on the other side, both to preserve it from the worm, and to make the ship slide smoother through the water. See CAREEN, DOCK.

BOÖTES, in astronomy, a constellation of the northern hemisphere, consisting of fifty-four stars in the British catalogue, twenty-eight in Tycho's, twenty-three according to Ptolemy, thirty-four in Bayer's, and fifty-two in Hevelius's.

According to fabulous history, this Bootes is supposed to be Arcas, the son of Calisto, daughter to Lycaon, king of Arcadia. The poetical story is thus: Lycaon receiving Jupiter into his house as a guest, took Arcas, his daughter's son, cut him into pieces, and placed him before Jupiter to eat, thinking by that means to prove whether his visitor was a god, which he had pretended to be. Jupiter perceiving the heinous fact, overturned the table, fired the house with lightning, and transformed Lycaon into a wolf; after which he gathered up the limbs of Arcas, put them together, and committed him to a nymph of Etolia, to be taken care

of. When Arcas, Bootes, or Artophilax, was come to man's estate, and was hunting in the woods, he by chance met with his mother Calisto, whom Juno had turned into the shape of a bear, and pursued her into the temple of Jupiter Lycæus, which, by the law of the Arcadians, was death for any man to enter: therefore Jupiter, fearing lest both should be slain, Calisto by her son, and Arcas by the law, out of pity translated them both into heaven.

There is only one unformed star in this constellation, which is between Bootes's legs, and by the Grecians is called Arcturus, because of all the stars near the Bear, named Arctos, this star is first seen near her tail in the evening; the poetical invention concerning which is thus: Icarus, the father of Erigone, having received of the god Bacchus a flagon of wine, to declare how good it was for mortal men, took it along with him into the territories of Athens, where carousing with it among certain shepherds, who being delighted with the pleasantness of the wine, which was a new kind of liquor to them, drank very freely, and were quickly glad to lay their heads to rest: but coming to themselves again after some time, and finding their heads scarce in good temper, they killed Icarus, supposing that he had either poisoned them, or given them something to intoxicate their brain. Erigone was ready to die for grief; but Jupiter, to allay her sorrow, placed her father in heaven between the legs of Bootes.

Bootes by some is called the Waggoner, because he is supposed to drive Charles's-wain, which is drawn by three oxen. Others call him Artophilax, and suppose him to be the keeper of the bear, or that the care of the bear is committed to him.

In the following Catalogue you have the right ascensions and declinations settled to the year 1770; likewise the annual variation in right ascension and declination in seconds and tenths.

BOOTY, whatever is taken from an enemy in time of war.

BOQUINIANS, in church history, a sect of heretics, so called from Boquinus their founder, who taught that Christ did not die for all mankind, but only for the faithful, and consequently was only a particular Saviour.

BORAGO, borage, in botany, a pentandrious plant, whose root is thick, fibrous, and white, from which spring forth several broad, roundish, rough, wrinkled leaves, of a darkish green colour,

which lie on the ground; the stalk is hairy, round, hollow, branched, and furnished with lesser leaves, which are placed alternately; the flowers, which grow on the tops of the branches, are generally blue, though sometimes reddish, or of a whitish colour; these are monopetalous, each having a short tube, and divided into five sharp-pointed segments; in the center are placed four germs, and a single stile, surrounded by five subulated filaments, which are joined together; the germs afterward becomes so many rough, roundish seeds: this plant is annual, and grows wild in many parts of England. The leaves of borage are accounted cordial, and good in removing faintness, for which reason the tops are frequently put into wine and cool tankards. Boerhaave recommends the expressed juice in all inflammatory diseases; the only official preparation is the conserve of the flowers.

BORAX, a fabulous animal, said to be of a middle nature, between an ass and a mule, and to have carried Mahomet in his aerial journeys from Jerusalem into Heaven.

BORAX, a saline substance, of which neither the origin, or the component parts are as yet known. It comes from the East-Indies in little crystalline masses, somewhat resembling small crystals of fat gem, mixed with earth and other impurities.

It is commonly said, that borax is prepared in the eastern countries, from a green saline liquor, which runs from certain hills, and is received in pits lined with clay, and suffered to evaporate by the sun's heat; that a bluish mud, which the liquor brings along with it, is frequently stirred up, and a bituminous matter which floats upon the surface taken off; that when the whole is reduced to a thick consistence, some melted fat is mixed, the matter covered with dry vegetable substances, and a thin coat of clay; and that when the salt has crystallized, it is separated from the earth by a sieve.

In the same countries is found, in considerable quantities, a native mineral alkaline salt on the surface of the earth, sometimes tolerably pure, more commonly blended with heterogeneous matters of various colours; the nitrum or natron of the ancients, the baurach of the Arabians. This alkali appears to be the same with the basis of the sea-salt, and with the lixivial salt of kali or kelp, and some other maritime plants. It differs from the common vegetable alkalis, in being milder and less acid in taste, assuming a crystalline appearance, not deliquiating in the air, or very slowly; forming with the marine acid a perfect sea-salt, with the nitrous quadrangular nitre, and with the vitriolic, a sal mirabile.

Mr. Pott received from Tranquebar, (where the greatest quantities of borax are made) a sand, under the name of ore of borax, with an account that cer-

certain acid vegetable matters were added in the preparation of the borax. The ore yielded, on elixation, only the mineral alkali, with a little sea-salt.

The mineral alkali appears, from experiment, to be a principal ingredient in borax. On treating borax with acids, about one fourth its weight of a peculiar saline substance, called sedative salt, is separated, and the residuum proves a combination of the alkali, with the acid employed: thus, when the marine acid is used, a genuine sea-salt remains; when the nitrous, a quadrangular nitre; and when the vitriolic, a sal mirabile. The substance separated, joined to the mineral alkali, to the basis of sea-salt, or to the salt of kali, recomposes borax again.

The properties of this substance, so far as they are known, are these: It is of a bright snowy whiteness, extremely light, composed of fine plates or scales, soft, and, as it were unctuous to the touch, of no smell, of a bitterish taste, accompanied with a slight impression of coldness. It dissolves difficultly in boiling water, and on the liquor's cooling, crystallizes on its surface into thin plates, which uniting and becoming larger, fall to the bottom. It likewise dissolves, by the assistance of heat, in rectified spirit of wine: the solution set on fire burns with a green flame. Moistened and exposed to a considerable heat, it in part sublimed; by repeated humectations the whole may be elevated: whilst dry, it proves perfectly fixed; it melts, emits aqueous vapours, and runs into a vitreous substance, dissoluble again as at first: neither the glass nor the salt itself are affected by the air. It makes no change in the colour of blue flowers. It unites with the common alkaline salts, in some degree neutralizes, and renders them capable of crystallization. It is said to expel from alkalies every acid except the vitriolic, though expelled itself by every acid from the alkaline basis of the borax.

Thus we find borax composed of two principles, one every where plentiful, another which has not hitherto been obtained but from borax itself; the last in the smallest proportion. How far this peculiar substance is natural or artificial, of mineral or of vegetable origin, is wholly unknown.

With regard to the refining of borax, the rough salt is said by some to be dissolved in lime-water, by others in a lixivium of caustic alkali, and by others in alum-water. This much is certain, that borax dissolved in common water, and crystallized in the common manner, forms extremely small crystals: that these differ in several respects from the refined borax of the shops, inasmuch that Cramer calls the latter not a purified but adulterated borax; that borax shoots into larger crystals when dissolved in lime-water, than in common water; and when the vessel is covered, and a gentle warmth continued

during the crystallization, than in other circumstances.

It is observable, that borax, during its dissolution, appears tenacious, and adheres in part to the bottom of the vessel: from this glutinous quality, peculiar to borax among the salts, it is employed by the dyers for giving a gloss to silks. It is also of the greatest use in soldering metals. See SOLDERING.

BORBONIA, in botany, a genus of diadelphious plants, the flower of which is pentapetalous and papilionaceous; the fruit is a round pointed pod, with one cell, containing a kidney-shaped seed. One of the species of borbonia grows naturally at the Cape of Good-Hope, where it rises to the height of ten or twelve feet, having slender stems dividing into several branches, which are furnished with stiff leaves, placed alternately, and are narrow, long, and acuminate; the flowers come out from between the leaves at the ends of the branches, and are yellow, much resembling those of broom.

BORBORITES, *Borboritæ*, in church history, a sect of Gnostics in the second century, who, besides embracing the errors of these heretics, denied the last judgment.

Their name comes from *βορβορος*, filth, on account of a custom they had of daubing their faces and bodies with dirt and filth.

BORDAT, in commerce, a small narrow stuff, which is manufactured in some parts of Egypt, particularly at Cairo, at Alexandria, and at Damietta.

BORDERS, in gardening, are of four sorts: those are the most common that are continued about parterres without any interruption, and wrought with a gentle rising in the middle, like an ass's back, and planted with low shrubs and flowers.

The second sort of borders are such as are cut into compartments, at convenient distances, by small passages, and being also raised in the middle, as before-mentioned, are likewise set off with shrubs.

The third sort are such as are laid even and flat, without flowers, having only a verge of grass in the middle, being edged with two small paths, raked smooth and fanded. These are sometimes garnished with flowering shrubs, and flowers of large growth; or with vases and flower-pots placed regularly along the middle of the verge of grass.

The fourth sort are quite plain, and are only fanded, as in the parterres of orangery; and are filled with cases ranged in a regular order along those borders, which are edged with box on the sides next the walks; and on the other, with verges and grass-work next the parterre. Sometimes a yew is planted between each case, which makes the border appear richer, and the parterres handsomer, during the winter season.

Borders are either made straight, circular, or incants; and are turned into knots, scrolls, volutes, and other compartments.

Florists also make borders, either in long walks, or detached; and in these they raise their finest and choicest flowers. These are frequently encompassed with border-boards painted green, which makes them look exceeding neat.

But in large parterres, this is not to be expected; since if they be stocked with flowers, succeeding one another in their several seasons, it is sufficient, so that nothing appears bare and naked.

It is usual to discontinue the borders at the ends next to the house, that the embroidery and rise of the parterre may not be hidden by the shrubs and flowering plants, and that the design may be better judged of.

And sometimes there are branched out of it foliage, palm-leaves, and shells sporting among the fands.

As the modern taste of parterres, scroll borders, and fret-work in box, has been justly banished our gardens: so I have only mentioned them here, to expose the taste of those architect-gardeners, who have no idea of the noble simplicity of an open lawn of grass, properly bounded by plantations; but instead of this, divide that part of the garden, near the house, into various forms of borders edged with box, and sand or gravel-walks leading about them; by which the ground is cut into many angles, scrolls, &c. which is very hurtful to the eye of a judicious person; therefore, where flowers are desired, there may be borders continued round the extent of the lawn, immediately before the plantations of shrubs; which, if properly planted with hardy flowers to succeed each other, will afford a much more pleasing prospect than the stiff borders made in scrolls and compartments, after the French manner, can possibly do.

These borders may be made six or eight feet wide, in proportion to the extent of the garden, and size of the lawn: for a small lawn should not have very broad borders; nor ought a large lawn to be bounded by small borders; so that a due proportion should be always observed in the laying out of gardens. *Miller's Gardener's Dictionary.*

BORD-FREE. See the article **FREE**.

BORD-HALFPENNY, a small roll, by custom paid to the lord of the town for setting up boards, tables, booths, &c. in fairs and markets.

BORD-LANDS, the demesnes which lords keep in their hands for the maintenance of their board or table.

BORD-LODE, a service required of tenants to carry timber out of the woods of the lord to his house. It is also used to signify the quantity of provision which the bordarii or bordmen paid for their bord-lands,

BORD-SERVICE, the tenure of bord-lands, by which some lands in certain places are held of the bishop of London, and the tenants now pay fixpence per acre, in lieu of finding provision anciently for their lord's table.

BORDURE, in heraldry, a cutting off from within the escutcheon all round it, about one fifth of the field, serving as a difference in a coat of arms, to distinguish families of the same name, or persons bearing the same coat. If the line constituting the bordure be straight, and the bordure be plain, then in blazoning you must only name the colour of the bordure.

Bordures are sometimes ingrailed, gobonated, invicted, &c. See the articles **INGRAILED**, &c.

If the bordure be charged with any part of plants or flowers, the term is verdoy of trefoils, or whatever flower it be. If it consists of ermins, vair, or any of the furs, they say purflew of ermins, &c. If the bordure be charged with martlets, the word is charged with an enalyron of martlets, &c.

Bordures are symbols of protection, favour, and reward, and as such, kings bestow them on those they have a value for.

BORE, among engineers, denotes the diameter of the barrel of a gun, or cannon, or rather its whole cavity.

Square BORE, among mechanics, a square piece of well-tempered steel, fitted into a handle, serving to widen holes, and making them perfectly round.

BOREAL, in a general sense, something relating to the north. Thus,

BOREAL SIGNS, in astronomy, are those six signs on the northern side of the equinoctial, or the first six signs of the Zodiac, viz. Aries, Taurus, Gemini, Cancer, Leo, and Virgo.

Aurora-BOREALIS. See **AURORA**.

BOREAS, a Greek name, now in common use for the north-wind.

Pezron observes, that anciently Boreas signified the north-east wind, blowing at the time of the summer solstice. Boreas is represented, in painting, like an old man with a horrible look, his hair and beard covered with snow or hoar-frost, with the feet and tail of a serpent.

BORECOLE, *brassica*, in botany, a species of the cabbage. See **CABBAGE**.

BORING, in a general sense, the art of perforating or making a hole through any solid body.

BORING of Water Pipes. See **PIPES**.

BORING, in farriery, an operation in use for the cure of wrenched shoulders in horses. It is this: having cut a hole in the skin, over the part affected, they blow it up with a tobacco-pipe, as a butcher does a shoulder of veal; after which they thrust a cold flat iron, like the point of a sword blade, eight or ten inches up between the shoulder-blade and the ribs: this they call boring.

BORING, in mineralogy, a method of piercing the earth with scooping-irons, which, being drawn back at proper times, bring up with them samples of the different strata thro' which they have passed; by the examination of which the skilful mineralist will be able to guess whereabouts a vein of ore may lie, or whether it will be worth while to open a mine there or no.

BOROUGH, BURROUGH, BOROW, or BURGH, a corporation, or town, which is not a city. The word, in its original signification, meant a company, consisting of ten families, which were bound together as each other's pledge. Afterwards borough came to signify a town having a wall or some kind of enclosure round it: and all places that in old time had the name of borough, it is said, were fortified or fenced in some shape or other. Borough is a place of safety and privilege: and some are called free burghs, and the tradesmen in them free burgeses, from a freedom they had granted to them originally, to buy and sell without disturbance, and exempt from toll.

BOROUGH is now particularly appropriated to such towns or villages as send burgeses or representatives to parliament, whether they be incorporated or not.

They are distinguished into those by charter or statute, and those by prescription or custom: the number in England is 149, some of which send one, but the most of them two representatives.

Royal Boroughs, in Scotland, are corporations created for the advantage of trade, by charters granted by several of their kings, having the privilege of sending commissioners to represent them in parliament, besides other peculiar immunities. They form a body of themselves, and send commissioners each to an annual convention at Edinburgh, to consult the benefit of trade, and their general interest.

BOROUGH-ENGLISH, a customary descent of lands or tenements, in certain places, by which they descend to the youngest instead of the eldest son; or if the owner have no issue, to the younger instead of the elder brother. This custom goes with the land, although there be a devise or feoffment at the common law to the contrary. The reason of this custom, says Littleton, is because the youngest is presumed, in law, to be the least able to provide for himself.

BOROUGH-HEAD, or HEADBOROUGH, called also borough-holder, or burghholder, the chief man of the decenna, or hundred, chosen to speak and act in behalf of the rest.

Headborough also signifies a kind of head constable, where there are several chosen as his assistants, to serve warrants, &c. See the article **CONSTABLE**.

BORRELLISTS, in church history, a Chris-

tian sect in Holland. They are a kind of anabaptists; but they have some very particular opinions. They reject the use of churches, of the sacraments, public prayer, and all other external acts of worship. They assert, that all the Christian churches of the world have degenerated from the pure apostolical doctrines, because they have suffered the word of God, which is infallible, to be expounded, or rather corrupted, by doctors, who are not infallible. They lead a very austere life, and employ a great part of their goods in alms.

BOS, the ox, in zoology, a genus of quadrupeds, of the order of the pecora, the characters of which are, that the horns are hollow and turned forward, bent like crescents, and smooth on the surface.

Of this genus, authors enumerate the five following species, viz. 1. The common tame kind. 2. The bonafus. 3. The bison. 4. The bubalus. 5. The urus.

BOSCAGE, the same with a grove, or thicket.

BOSCAE, in a law sense, is that food which trees yield to cattle, as mast, &c. But Manwood says, to be quit of boscaie, is to be discharged of paying any duty for wind-fall wood in the forest.

BOSCAE, among painters, denotes a landscape representing much wood and trees.

BOSEA, in botany, a genus of pentandrious plants, whose flower is apetalous; the fruit is a globose berry of one cell, containing a single roundish acuminate seed.

BOSPHORUS, in geography, is a long, narrow sea, running in between two lands, by which two continents are separated, and by which way a gulf and a sea, or two seas, have a communication one with the other; as the Thracian Bosphorus, now called the Straights of Constantinople.

BOSQUETS, in gardening, groves so called, from *boschetto*, an Italian word, which signifies a little wood; they are compartments in gardens formed by the branches of trees, disposed either regularly in rows, or wildly and irregular, according to the fancy of the owner. A bosquet is either inclosed with palisadoes, or hedges of lime, elm, hornbeam, or beech, which should be kept well sheared, and not suffered to rise too much, that the heads of the trees may be fully seen over them, and the stems only hid from the sight. The ground should be kept smooth, or else covered with grass. In planting bosquets, care should be taken to mix the trees which produce their leaves of a different shape, and various shades of green, hoary, and mealy leaves, so as to afford an agreeable prospect; but it is improper to mix evergreens with deciduous trees, for besides the ill effect it hath to the sight (especially in winter) they seldom thrive well together. Bosquets are only proper for spacious gar-

gardens, and require a great expence in their first making, as also in keeping them up.

BOSSAGE, in architecture, a term used for any stone that has a projecture, and is laid rough in a building, to be afterwards carved into mouldings, capitals, coats of arms, &c.

BOSSAGE is also that which is otherwise called rustic work, and consists of stones which advance beyond the naked, or level, of the building, by reason of indentures or channels left in the joinings. These are chiefly used in the corners of edifices, and thence called rustic quoins. The cavities or indentures are sometimes round, sometimes chain-framed, or bevelled, sometimes in a diamond form, and sometimes inclosed with a cavetto, and sometimes with a listel.

BOSTANGIS, in the Turkish affairs, persons employed in the garden of the seraglio, out of whose number are collected those who are to row in the grand seignior's barges, when he has a mind to divert himself with fishing, or take the air upon the canal. They who row on the left hand are only capable of mean employments in the gardens; but they who row on the right-hand may be promoted to the charge of *bostangi-bachi*, who has the general intendency over all the grand seignior's gardens, and commands above ten thousand *bostangis*.

BOTALE FORAMEN, in anatomy, a name given to the foramen ovale, from Botall, physician to Charles IX. to whom the discovery of it is ascribed. See the articles **HEART** and **FORAMEN OVALE**.

BOTANIST, a person skilled in botany, and consequently, by systematic rules, capable of assigning to every plant its proper characters and name.

BOTANY, the science which treats of plants, their several kinds, their forms, virtues, and uses. The word is Greek, *botanē*, an herb, which is derived from *bōō*, to feed; because most animals feed on vegetables.

Botanists divide the vegetable world into genera and species, though they have not all agreed from what consideration. Tournefort, a late and good writer on botany, after a long and accurate discussion, chose, in imitation of Gesner and Columna, to class and regulate plants by the flowers and fruit, considered together; so that all plants which bear a resemblance in those two respects, are of the same genus; i. e. that they all agree in some one common character, in respect of the structure of certain parts, whereby they are distinguished from all other plants which are of the same family; after which, the respective differences as to root, stem, and leaves, makes the different species or subdivisions. He asserts, that he never hitherto met but with twenty-two different figures of flowers, which are to regulate entirely the genus or class of plants; and which is all that is to be retained in

the memory, to be capable to descend to near seven hundred genera, comprehending upwards of two thousand species of plants. According, therefore, to Tournefort's system of botany, all plants are ranged under one or other of the following classes; 1. Plants with monopetalous, campaniform, or bell-shaped flowers. 2. Those with monopetalous, infundibuliform, or funnel-shaped flowers. 3. Plants with anomalous monopetalous flowers. 4. Plants with polypetalous labiated flowers. 5. Plants with polypetalous cruciform flowers. 6. Plants with polypetalous rosaceous flowers. 7. Plants with polypetalous, umbellated flowers. 8. Plants with caryophyllous, or pink-like flowers. 9. Plants with liliaceous, or lily-like flowers. 10. Plants with polypetalous papilionaceous flowers. 11. Plants with polypetalous anomalous flowers. 12. Plants with flosculous flowers. 13. Plants with semiflosculous flowers. 14. Plants with radiated flowers. 15. Plants with stameneous flowers. 16. Plants without flowers, but having visible seeds. 17. Plants with neither visible flowers nor seeds. 18. Trees with apetalous flowers. 19. Trees with apetalous amentaceous flowers. 20. Trees with monopetalous flowers. 21. Trees with rosaceous flowers. 22. Trees with papilionaceous flowers: the description of each see under their respective articles, **MONOPETALOUS**, **CAMPANIFORM**, &c. See also plate XXI. fig. 2. and *TOURNEFORT'S System*.

This system was generally approved of till lately; when Dr. Linneus, professor of botany and medicine at the university of Upsal in Sweden, founded a new system called the Sexual, on a discovery that there is in vegetables, as well as in animals, a distinction of the sexes. This was not wholly unknown to the ancients, but their knowledge of it was very imperfect; for tho' the generality of vegetables produce hermaphrodite flowers, containing within them the characters of both sexes; yet in the classes of monoecia and dioecia, the sexes are parted and allotted to different flowers; and particularly in the class dioecia, the sexes are even on different plants, the male growing on one hand, the female flowers on the other. Now this last circumstance the ancients had observed: indeed, it could hardly escape their notice; for the palm-tree, whose fruit was in esteem, being of the class dioecia, a very little observation was requisite to teach them, that in these trees the flowers of the male were necessary to ripen the fruit of the female. Accordingly we find, in the account given by Herodotus, (in his first book) of the country about Babylon, where the trees were in plenty, that it was a custom with the natives, in the culture of this plant, to assist the operations of nature, by gathering the flowers of the male-trees, and carrying them to the female: by this means they secured the ripening of the fruit, which might else, from

Clavus

unfavourable seasons, or the want of a proper intermixture of the trees of each sex, have proved precarious, or at least, not to have been expected in equal quantities. It seems somewhat extraordinary that this discovery should not have led the antients to develop the whole process of nature in the propagation of the various species of vegetables; and yet it does not appear, by any of their writings that are handed down to us, that they went farther than this obvious remark upon the palm-tree, and some similar notions concerning the fig. They had indeed, from what they saw in these plants, formed a notion that all others were male and female likewise; but this notion was false, the far greater part having hermaphrodite flowers; and serves to convince us, that what they discovered of the palm or fig, was only a right guess, and not founded on any knowledge of the anatomy of flowers, either in those trees or any others.

In this dark state, the doctrine of the sexes of vegetables remained not only through all the ages of antiquity, but almost to the end of the last century; the moderns seeing no more of this doctrine than the antients had done before them; and hence we have to this hour in use the false distinctions of male and female species of cornus, peony, cistus, and many others, which have all hermaphrodite flowers, the distinction, in these cases, being grounded on nothing more than some difference in the habit of the two species, with which the sexes are no ways concerned. The honour of having first suggested the true sexual distinctions in plants, appears to be due to our own countryman Sir Thomas Millington, from whose hints Dr. Grew, as the doctor himself acknowledges, was led to the observations he has given on this subject in his *Anatomy of Plants*, p. 171. After this, Camerarius, Moreland, Geoffroi, Vaillant, Blair, Jussieu, and Bradley, pursued their enquiries and experiments so far as to remove all doubt concerning these discoveries; and lastly, Linnæus founded thereon a new system of botany, which we will explain from the *Ratio Operis*, affixed to his *Genera Plantarum*, printed anno 1764. This celebrated botanist says,

“Whatever knowledge we are able to acquire of things, depends on a true method of arranging them, by which we distinguish their similitudes and differences; the more natural distinctions such method comprehends, the clearer are our ideas of objects; the more things our conceptions are employed upon, the greater is the difficulty, and, indeed, the necessity of methodizing them. Our great Creator has no where afforded the senses of mankind so many objects of contemplation as in the vegetable kingdom, which covers and fills the whole of that globe we inhabit; if a true method therefore is any where of consequence, it certainly must be here, if we hope to acquire a clear notion of vegetables. This made Cæsalpine say, ‘that

‘unless plants, like an army encamped, were reduced into orders and classes, there could be nothing but confusion and uncertainty.’ He understands vegetables who knows how to join such as resemble each other, and to separate those that do not. He is a botanist who can give like names unto like, and distinct names to distinct vegetables, so as any person may understand them. The names of plants are according to their genus, and also, where there are many species, specific; and ought to be certain and fixed, not vague, mutable, or such as may be variously applied. Now in order to make them such, they must be ascribed to determined, not uncertain, signs; for where the latter are vague and indistinct, their names must be so likewise, and consequently, the ideas of the botanist confused.

“There are as many species as Infinite Being has produced diversified and regular forms in the globe; which forms, according to the constant laws of generation, produce more in their own likeness: there are, therefore, as many species as there are at this day different forms or structures of plants, taking no notice of such little varieties which place or chance now and then exhibit. There are as many genera as there are common and relative attributes belonging to the different species at first created; revelation, discoveries, and observation, confirm this: hence all genera are natural. The limits therefore of each genus are to be closely and diligently observed, however great or difficult the task; for, as Cæsalpine says, ‘when the genera are confounded, every thing else must be so too.’

“That it pleased Infinite Wisdom to distinguish the genera of plants from their fructification, was the discovery of the last age; and of Conradus Gesner first of all, the ornament of his time, as is evident from his posthumous letters, published from the originals by Camerarius; but the first who brought this discovery into use was Andrew Cæsalpinus, which yet would soon have expired, had it not been revived by the care of Robert Morrison, and cultivated by Pitt and Tournesort, according to clear and systematic rules, and lastly, fully established by all who have since approved themselves masters in the art.

“This foundation being settled, persons qualified for labours of this kind began to avail themselves thereof, and raise thereon their several systems, all indeed with the same alacrity, and for the same end, but with very unequal success; to few only was the fundamental principle rightly understood. He who proposes to teach an art must descend from generals to particulars; on the contrary, the inventor must ascend from particulars to generals. Different writers have laid down different parts of fructification for a leading principle, from whence they descended, according to the usual method of division, from classes first to orders, till they came

to species, and thus with hypothetic and arbitrary principles, broke and tore in pieces the natural genera, and did a violence to nature. For example, one denies from the fruit, that the peach and almond-tree can be of the same genus; another, from the regularity of the petals, denies the same with valerian and valerianoides; while a third, from the number of the petals, ascribes to different genera the flax and olive. Another, from the sex, denies, that the linum and radiola, the hermaphrodite nettle and dioica, &c. can possibly be united together under the same genus; they further say, that they cannot even be joined in class, much less in genus: but the misfortune is, these writers do not observe, that the classes, such as they be, are of their own construction, while the Creator himself has formed the genera; and from this error arise so many erroneous genera, so many controversies among authors, so many improper names, and so much confusion, that they have at length really brought things into such a situation, that as often as a new system-writer starts up, the whole botanical world is alarmed; and to speak the truth, I really am at a loss to know, whether these system-writers have done most good or harm. This is a misfortune which physicians, apothecaries, and gardeners, long lamented, and I must own, not without reason. Their theory would have been the best, if it had pleased the great Creator to have produced all the fructifications of the same genus equally resembling each other, as the individuals of the same species do; which not being the case, there is nothing left for us to do, but, as we cannot be ourselves the lords of nature, and cannot create every plant over again according to our own conceptions, to submit ourselves to the laws of nature, and with a close and vigilant application, accustom ourselves to read the characters inscribed on plants. If it be granted, that each different mark of fructification is sufficient to distinguish the genus, why should we hesitate a moment to pronounce that there are almost as many genera as species? for there are hardly any flowers of the two species known to us so like each other, but there is some difference in their parts; therefore, I would advise all sensible botanists to acknowledge, if they would wish to obtain any certainty in the art, that all the genera and species are natural, without which fundamental point we cannot proceed with any degree of certainty. We will suppose the great Creator of all things, from the beginning, to have created only one species of each genus; we will also suppose these first species afterwards, either in the beginning or process of time, to have been fecundated by species of other genera; from thence it would follow, that new species would arise, while these, in some measure, would, in the form of the flower, resemble the fe-

male, but the plant be like the male." See *Amen. Acad.* vi. p. 279.

"This postulatam being granted, let each proceed according to his own method, and divide these genera into orders and classes. Cæsalpinus, Herman, Ray, &c. take it from the fruit; Tournefort, from the form of the corolla; Rivinus, from the number and equality of the petals; Magnol, from the calyx or cup; and none of these methods are bad; for it is of little signification by what method we come at the genera, provided it is an easy one. That is to be preferred which leads the surest to it, and is the most universal; for it is scarcely to be believed, there are any persons born with to perfect a memory, as, without a system, to retain all the genera; for orders are only subaltern classes, and none will deny but it is easier to distinguish a few genera, than all: it is an easy matter to refer the greatest part of the known genera to their proper natural classes, but it is therefore more difficult with regard to the rest; nor is it to be expected, that our age will be able to see any natural system, or hardly our descendants, for a long time to come; yet, as we study to know plants, we must, in the mean time, make use of artificial and succedaneous classes. The natural classes would please every body, provided any one could find out their characters; but to retain these without a character comprehending the proper genera, and rejecting others, would be the same thing as rejecting every method. The ancients, in the time of the Bauhines, stuck closely to the natural classes; but a character was wanting, from their not having rightly discovered the parts of fructification, when Tournefort descended with the bright light of fructification to the genera, till then obscure. For example, the melianthus, epimedium, hypocoum, tumaria, impatiens, &c. must necessarily agree in the natural order; but who will, from any part of the fructification, undertake to give a combining and distinguishing character? Composite flowers comprehend the corymbus with a single flowered cup, the erigeron with four filaments, the kuhnia with distinct antheræ, the strumphia with berried fruit: now who could ever give a character applicable to these and not to others? Taking then the natural genera, and treating properly on them, two things are required, viz. That the true species, and no other, be referred to their genera; and that every particular genera be circumscribed within its true bounds and limits, which we denominate general characters.

"In looking over writers, I find none of these characters fixed and certain before Tournefort; therefore, to him I ought to ascribe, not without reason, the honour of the invention respecting the genera. Other systematic writers, of different methods, have also delivered them; but I understand none of them except Tournefort; and those who have

have followed him; as Plumier, Petit, Boerhaave, Vaillant, Dillenius, Ruppius, Pontedera, Buxbaum, Mitchel, and a few others; most of whom, although they deviated from the classes and orders, or the method of Tournefort, nevertheless, were his followers in the genera.

“Tournefort assumed the petals and fruit for the diagnostic marks of the genera, and no other parts; and his followers, in general, did the same; but writers of a later date, overpowered with an abundance of new and lately discovered genera, found out that these parts alone were insufficient to distinguish all the genera; and, on that account, thought themselves obliged to have recourse to the look and appearance of the plants; such as, the leaves, the situation of the flower, the stalk, the root, &c. that is, they deviated from the very fundamental of fructification, and fell into the original barbarism. However, it must be confessed, that the parts described by Tournefort are not sufficient; for if only the petals and fruits are to be taken account of, I will deny the whole mystery of fructification: but I would ask, Whether reason ever told us, that the marks are to be drawn from these alone? What revelation, or what arguments drawn *a priori*, or *a posteriori*? Certainly none. Does there not plainly appear many more parts in fructification? Why are some to be taken notice of, and others neglected? Were they not all created alike by the same hand? Are they not all necessary parts? We can discern in the calyx, 1. The involucre; 2. The spathe; 3. The perianthium; 4. The amentum; 5. The glume; 6. The calyptra. In the corolla, 7. The tube or claws; 8. The border; 9. The nectarium. In the stamina, 10. The filaments; 11. The antheræ. In the pistillum, 12. The germen; 13. The style; 14. The stigma. In the pericarpium, 15. The capsule; 16. The pod; 17. The legumen; 18. The nut; 19. The drupe; 20. The berry; 21. The apple. In the seed, 22, 23. its corona. In the receptacle, 24. Of its fructification; 25. Of the flower; 26. The fruit. Here are more parts, more characters, than in the alphabets of languages; all these marks serve us as so many letters of vegetables, in reading of which we learn the characters of plants: they were wrote by their Maker, and it is our business to read them.

“Tournefort, with his characters, did wonders; but as there are since so many new genera discovered, I shall adhere to his principles, but shall enlarge them with new discoveries, as the science encreases.

“I do not approve of drawings alone in determining the genera. Before the use of letters, it was necessary to express things by picturesque representations, where it could not be done by words; but, by the invention of letters, we have a more certain and easy method of communicating our ideas:

so it is in botany, before the discovery of letters, these figures were of the greatest utility, but these have afforded a much shorter way.

“Characters of the genera are obtained in a threefold manner, factitious, essential, and natural. Factitious characters has fixed a single mark on the genus, by which it distinguishes one from the rest belonging to the same order, but not from others. A character of this sort may be easily understood by any one, and is instituted by means of synoptic tables, as it is delivered by Ray, in the first edition of his Synopsi; also by Knautius and Kramerus. Certainly, if there were never any doubts raised concerning the class or order, and all the genera existing in nature were discovered, this would be the easiest method: but as this neither is, or can be, the case, the character is deceptive; for when any new genus is discovered, the nearest characters, and such as arise from the branch to which they should be annexed, become fallacious.

“The essential character gives the most certain mark to the genus it is applied to, and recommends itself for its brevity and exactness. As for example, in the *parnassia*, *nigella*, *hellebore*, *ranunculus*, &c. it is very readily perceived by the nectarium alone; but it is doubtful, whether this character can be obtained in all the genera; and I would fain see the essential character in the umbelliferous flowers and others.

“I therefore lay down those for natural characters, which exhibit all the marks of fructification obvious and common. The use and prerogatives of natural characters are as follow: one of this kind is applicable to all methods, if the system is raised on that never-failing foundation, the fructification. Let any one take a method from the calyx, or the corolla, or the stamina, or the pistillum, or the fruit; we shall still have the same natural character where there is the same genus. Formerly, it was necessary to compose as many characters of all the genera as there were systems; but in this it is not so: if even a thousand new genera were discovered, it would not, on that account, be necessary to add or take away a single mark from the nearest natural genus, as was necessary in all the rest.

“This character, or definition of genus, might be distinctly treated of without method, and might be easily retained and understood in any book. While it served under its proper class, it expresses the same idea. Were the names changed a thousand times, you perceive more marks than is necessary to distinguish the subject genus by from others; these are a proof that you have a true genus, and no other: whether any of these marks would be superfluous if all the genera were discovered, time only can determine.

“In describing the different parts of fructification, I have selected such marks as are certain and

real, not vague and loose. Some have assumed the taste, smell, colour, and also the size, without any proportional standard: you will not see me assume these; but the following four certain and fixed mechanical principles only; the number, the figure, the site, and the proportion. These four attributes, with the twenty-six characters before-mentioned, distinguish the genera from each other with so much exactness, that nothing can excel it: considering only these marks, nothing will be wanting to determine the genera, and the other marks will be superfluous; nor is there any occasion to have recourse to the habit or appearance of plants.

"In forming a character of this sort, we must take all the species that are known. The four obvious marks abovementioned are to be well described in all the parts of fructification, and those which do not agree with all the species are to be excluded; and those only which do agree therewith to be retained. As it is impossible for any one person to see all the species, he who sees the most, and observes in them such marks as are not similar, should exclude the same in forming a character, that posterity hereafter may see a complete work."

Having thus given, as far as it seems necessary, the new principles upon which the reformation of the former vicious systems of botany have been undertaken, we come to shew the method introduced by Linnæus.

Vegetables, according to him, are primarily divisible into three parts; 1. The root; 2. The herb, or plant itself; 3. The fructification: and in this order these parts might have been treated, were it not on account of the sexual system; it therefore became necessary to give up the order of the parts of the vegetable; and follow that of the system.

The system is divided, 1. Into classes; 2. orders; 3. genera, 4. species; 5. varieties.

From the number, situation, and proportion of the stamina, this curious botanist has arranged the whole family of plants under twenty-four classes, viz.

1. Monandria. 2. Diandria. 3. Triandria. 4. Tetrandria. 5. Pentandria. 6. Hexandria. 7. Heptandria. 8. Octandria. 9. Enneandria. 10. Decandria. 11. Dodecandria. 12. Icosandria. 13. Polyandria. 14. Didynamia. 15. Tetrady-namia. 16. Monadelphia. 17. Diadelphia. 18. Polyadelphia. 19. Syngenesia. 20. Gynandria. 21. Monoecia. 22. Dioecia. 23. Polygamia. 24. Cryptogamia. See them explained under their respective articles. See also LINNÆUS'S *System*.

These are the general classes of plants established by that excellent botanist, who farther subdivides them into orders, which he denominates monogynia, digynia, &c. from the number of pistils, or female parts of generation, found in each plant. See the articles MONOGYNIA, DIGYNIA, &c.

For a farther account of the botanical works of this celebrated author, we would refer the curious reader to his *Genera Plantarum*, *Species Plantarum*, *Philosophica Botanica*, and *Amoenitates Acad.* Vol. III. in which last he will find the history of botany divided into four epochs, viz. 1. *Epocha Patrum*; 2. *Fundatorum*; 3. *Systematicorum*; and, 4. *Reformatorum*. He will likewise find the principal works of botanists, both antient and modern, mentioned; and their progress in the science.

BOTE, *Bota*, in our old law books, signifies recompence or amends; thus a man-bote is a compensation for a man slain.

There are likewise house-bote and plough-bote, privileges to tenants, of cutting wood for making ploughs, repairing tenements, and likewise for fuel.

BOTRYS, in botany, a species of the chenopodium. See CHENOPODIUM.

BOTTLE-FLOWER, in botany; see the article CENTAUREA.

BOTTOM, in the marine, is used either to denote the bottom of a ship, or the bottom of the water; thus, in the former sense, we say, a clean or a foul bottom, a British, French, or Dutch bottom; and in the latter sense, a rocky, sandy, or oozy bottom.

BOTTOMRY, in marine commerce, a contract for borrowing money on the keel or bottom of a ship; so that the commander binds the ship herself, that if the money be not paid at the time appointed, the creditor shall have the ship.

BOTTOMRY is also where a person lends money to a merchant or adventurer, who wants it in traffic, and the lender is to be paid a much greater sum at the return of the ship, standing to the hazard of the voyage: on which account, though the interest be greater than the law commonly allows, yet is it not usury, because the money being supplied at the lender's hazard, if the ship perishes, he shares in the loss.

BOTTOMY. A cross bottomy, in heraldry, terminates at each end in three buds, knots, or buttons, resembling, in some measure, the three-leaved grass; on which account, Segoing, in his *Tresor Heraldique*, terms it *croix tressée*. It is the badge of the order of St. Maurice.

BOULDER-WALL, a kind of wall built of round flints or pebbles, laid in a strong mortar, and used where the sea has a beach cast up, or where there are plenty of flints.

BOULTINE, in architecture, is the workmen's term for a convex moulding, whose convexity is just one fourth of a circle; this is placed next below the plinth in the Tuscan and Doric capital.

BOUNTY, in commerce, a premium paid by the government to the exporters of certain British commodities, as sail-cloth, gold and silver lace, silk stockings, fish, corn, &c.

BOURDONEE, in heraldry, the same with pomee. See the article **POMEe**.

BOURIGNONISTS, the name of a sect among the Low-Country protestants, being such as follow the doctrine of Antoinette Bourignon, a native of Lisle, and apostate of the Roman catholic religion.

The principles of this sect bear a very near resemblance with those of the quakers, quakers, or fanatics. They conduct themselves by pretended revelations.

BOUTANT, or **ARCH-BOUTANT**, in architecture, a flat arch or part of an arch, abutting against the reins of a vault, to prevent its giving way.

A **Pillar BOUTANT** is a large chain or pile of stone, made to support a wall, terrace, or vault.

BOUTS-RIMEZ, in French poetry, a term signifying certain rhymes disposed in order, and given to a poet, together with a subject, to be filled up with verses ending in the same word and same order. In choosing the rhymes, it is usual to fix on such as seem the remotest, and have the least connection. Some authors fancy, that these rhymes are, of all others, the easiest; that they assist the invention, and furnish new thoughts.

BOW, *Arcus*, a weapon of offence made of steel, wood, horn, or other elastic matter, which, after being bent by means of a string fastened to its two ends, in returning to its natural state, throws out an arrow with prodigious force.

Bow, a mathematical instrument used formerly at sea, for taking the sun's altitude. It consisted of an arch containing ninety degrees, a staff, a shade-vane, a sight-vane, and an horizon-vane.

Bow, in naval architecture, the rounding part of a ship's side forward, beginning at where the planks arch inwards, and terminated where they close at the prow or stem; it is proved by experience, that a ship with a narrow bow is much better calculated for swiftness of sailing, than one with a broad bow, but not so well for a high sea, into which she always plunges or pitches her fore part very deep, for the want of sufficient breadth to repel the volume of water, which she so easily divides in her fall.

The former of these is called by seamen a lean, and the latter a bluff-bow.

On the Bow, in navigation, an arch of the horizon comprehended between the point of the compass which is right a-head, or to which a ship's stem is directed, and some object seen or discovered by trigonometry; as, We saw a fleet to the windward, three points on the bow; that is, three points from that part of the horizon which the ship stems. Also having found the distance of any place by calculation, it is occasionally said to be *on the Bow*.

When a Ship sails with a side-wind, the bow

next to the wind is called the weather-bow, and the other the lee-bow; any object distant from the latter is not said to be *on*, but *under* the lee-bow.

Bow, among builders, is a beam of wood or brass, with three long screws that govern or bend a lath of wood or steel to any arch, and is of use for drawing arches that have large radii, &c. which cannot be struck with compasses.

Bow, in music, a small machine, which, being drawn over the strings of a musical instrument, makes it resound. It is composed of a small stick, to which are fastened eighty or an hundred horse-hairs, and a screw, which serves to give these hairs the proper tension. In order that the bow may touch the strings briskly, it is usual to rub the hairs with rosin.

Bow, among artificers, an instrument so called from its figure; in use among gunsmiths, locksmiths, watchmakers, &c. for making a drill go. Among turners, it is the name of that pole fixed to the ceiling, to which they fasten the cord that whirls round the piece to be turned.

Bows of a Saddle are two pieces of wood laid archwise to receive the upper-part of a horse's back, to give the saddle its due form, and to keep it tight.

BOWER, in gardening, a place under the cover of trees; it differs from an arbour by its form, it being generally of a round or square shape, whereas arbors are built long and arched.

BOWLINE, in the marine, a rope fastened to the leech or perpendicular edge of the square-sails, in three or four parts called bristles; they are only used on the weather-side, or the side of the sail next the wind, to keep that part of it tight forward, and prevent it from shivering, which would always be the case, as the ship sails on a scant side-wind. See this more particularly explained under the articles **BRIDLE** and **CLOSE-HAWLING**.

BOWLING-GREEN, in gardening, a kind of lawn, laid with fine turf, and designed for the exercise of bowling. Bowling-greens are generally of a square form, and should be made nearly level, particularly the sides, the middle being rather the highest.

BOWSING, in the marine, drawing on any body with the powers of a tackle; or using a tackle in a method where it does not suspend the body drawn upon, which is then called hoisting.

BOWSPRIT, in naval affairs, a large boom or mast which projects over the stem, to carry sail on, and govern the fore-part of the ship to counter-balance the sail carried behind, or in the after-parts; and likewise to support the fore-mast, by ropes stretched from the mast-head to the outer-end of the bowsprit, called stays. See **BOOM** and **STAYS**.

BOX, in its most common acceptation, denotes a small chest or coffer for holding things.

Box of a Plough, the cross piece in the head of a plough, which supports the two crow-staves. See **Plough**.

Box, in zoology, the same with boops. See the article **BOOPS**.

Box-TREE, in botany; see the article **BUXUS**.

Box-THORN, in botany; see the article **LYCIUM**.

Box-HAWLING, or **VAUX-HAWLING**, in navigation; see the article **HAWLING**.

BOXING, in navigation, arranging the headsails of a ship aback, when, by the neglect of the steersman, she had made some declination from the line of her course, and had inclined her motion nearer to the direction of the wind, than the sails would stand full side-ways. See **ABACK**.

The use of boxing at that time is to act with greater impulse on the ship's fore-part than usual, till the force impressed compels her to change her position, veer farther from the course of the wind, and return into the line of motion from which she had deviated.

BOYAU, in fortification, is a particular ditch separated from the main trench, which in winding about encloses different spaces of ground, and runs parallel with the works and fences of the body of the place; so that when two attacks are made at once, near one to the other, the boyau makes a communication between the trenches, and serves as a line of contravallation, not only to hinder the sallies of the besieged, but also to secure the miners. But when it is a particular cut that runs from the trenches to cover some spot of ground, it is then drawn parallel to the works of the place, that it may not be enfiladed, or that the shot from the town may not scour it.

BOYES, idolatrous priests among the savages of Florida.

Every priest attends a particular idol, and the natives address themselves to the priest of that idol to which they intend to pay their devotion.

The idol is invoked in hymns, and his usual offering is the smoke of tobacco.

BOYLE'S LECTURES, a course of sermons set on foot, in London, by the honourable Robert Boyle in 1691; the design of which is to prove the truth of the Christian religion against infidels, without descending to any controversies among Christians.

BRABEUTES, or **BRABEUTA**, *βραβευτης*, in antiquity, an officer among the Greeks, who presided at the public games, and decided controversies that happened among the antagonists in the gymnical exercises. The number of brabeutæ was not fixed; sometimes there was only one, but more commonly they amounted to nine or ten.

BRABEJUM, the African almond, in botany, a tetrandrous plant, which rises with an upright soft stem, full of pith within, and covered with a

brown bark; from the stem issues forth several horizontal branches on every side, and at every joint, the lower ones being the longest, and every tier diminishing to the top, so as to form a kind of pyramid. The leaves come out all round the branches at each joint, which are from four to five inches long, and half an inch broad at the middle: these are of a deep-green on their upper-side, and pale underneath, indented on their edges, and standing on very short foot-stalks. The flowers are produced toward the end of the shoots, and come out from between the leaves quite round the branches; these are of a pale colour, inclining to white, and are composed of four narrow obtuse petals, in the lower part erect, forming a kind of tube, and in the upper turned backward. In the bottom of the petals are inserted four capillary filaments, topped with small antheræ; in the center is placed a small villose germen, which afterwards becomes a hairy drupe, of the drier kind, of an oval figure, containing a kernel of the same shape.

This plant is a native of the country about the Cape of Good-Hope; and in this climate must be sheltered in a green-house in winter.

BRACE is commonly taken for a couple or pair, and applied by huntmen to several beasts of game, as a brace of bucks, foxes, hares, &c.

BRACE, or **BRASSE**, is also a foreign measure, answering to our fathom. See **FATHOM**.

BRACE, in architecture, is a piece of timber framed in with bevel-joints, and is used to keel the building from swerving either way. It is called a strut, when it is framed into the kindlesses and principal rafters.

BRACES, in the marine, the ropes fastened to all the yard-arms or yard-ends in a ship, except the mizen-yard: their use is to wheel or traverse the sail-yards about the masts, in a direction parallel to the horizon, as the sails are to be shifted to the variation of the wind.

BRACED, in heraldry, a term for the intermingling three chequerons.

BRACELET, an ornament worn on the wrist, much used among the ancients. It was made of different materials, and in different fashions, according to the age and quality of the wearer.

BRACHIÆUS, in anatomy, an oblong, thick, and broad muscle, lying immediately on the anterior part of the lower half of the os humeri. The upper part of it is forked or sloped, and at the bending of the joint of the elbow, the lower part contracts.

It is fixed to the surface of the os humeri by a great number of fleshy fibres, from the lower insertion of the deltoides, almost down to the two fossæ at the lower extremity of the bone, and from one edge of the fore side of this lower extremity to the other. The fibres are for the most part longitudinal, those nearest the surface of the muscle being

ing longest, the more internal growing gradually shorter.

The lateral fibres are a little oblique, and this obliquity increases in those that lie lowest. These lateral fibres are partly fixed in the intermuscular ligaments of the os humeri, of which ligaments, that which lies toward the internal condyle is longer and broader than that toward the external condyle. The lowest of these fibres are very oblique, and form on each side a kind of small separate fasciculus.

In passing over the joint, all these fibres contract in breadth, and afterwards end in a strong flat tendon inserted in the muscular impression, which is directly below the coronoide apophysis of the ulna. This muscle adheres very strongly to the capsular ligament, and some of its fleshy fibres terminate therein.

The sloped or forked superior extremity of this muscle embraces the large tendon of the deltoides. The internal point of the fork meets the inferior insertion of the coraco-brachialis; and the fore-side of the whole muscle is covered by the two fleshy bodies of the biceps.

BRACHIUM, ARM, in anatomy, one of the superior extremities of the human body, comprehending the scapula, the os humeri, the cubit, and the hand. See the articles **SCAPULA, ARM, &c.**

BRACHMANS, a sort of Indian philosophers, known to the ancient Greeks by the name of Gymnosophists. The ancient Brachmans lived upon herbs and pulse, and abstained from every thing that had life in it. They lived in solitude, without matrimony, and without property; and they wished ardently for death, considering life only as a burden. The modern Brachmans make up one of the casts or tribes of the Banians. They are the priests of that people, and perform their office of praying and reading the law with several mimical gestures, and a kind of quavering voice. They believe that, in the beginning, nothing but God and the water existed; and that the Supreme Being, desirous to create the world, caused the leaf of a tree, in the shape of a child playing with its great toe in its mouth, to float on the water: from its navel there issued out a flower, whence Brama drew his original, who was intrusted by God with the creation of the world, and presides over it with an absolute sway. They make no distinction between the souls of men and brutes, but say the dignity of the human soul consists in being placed in a better body, and having more room to display its faculties. They allow of rewards and punishments after this life; and have so great a veneration for cows, that they look on themselves as blessed, if they can but die with the tail of one of them in their hand. They have preserved some noble fragments of the knowledge of the ancient

Brachmans. They are skilful arithmeticians, and calculate, with great exactness, eclipses of the sun and moon. They are remarkable for their religious austerities. One of them has been known to make a vow, to wear about his neck a heavy collar of iron for a considerable time: another to chain himself by the foot to a tree, with a firm resolution to die in that place; and another to walk in wooden shoes stuck full of nails on the inside. Their divine worship consists chiefly of processions, made in honour of their deities. They have a college at Banara, a city seated on the Ganges.

BRACHYGRAPHY, the art of short-hand writing.

The word is compounded of the Greek *βραχυς*, short, and *γραφω*, to write.

BRACKET, among carpenters, &c. a kind of wooden stay, serving to support shelves, and the like.

BRACKETS, in naval architecture, short crooked timbers, somewhat resembling knees: they are fixed under the frame of a ship's-head, to support the gratings.

BRACKETS, in gunnery, are the cheeks of the carriage of a mortar: they are made of strong planks of wood, nearly of a semi-circular figure, and bound round with thick iron plates, which are fixed to the bed by four bolts, rising up on each side the mortar, serving to keep her at any elevation, by means of some strong iron bolts, which go through these cheeks or brackets.

BRACTEA, in natural history, denotes a spangle, or thin flake of any substance.

BRACTEA, in botany, denotes the floral leaf. See the article **FLORAL LEAF.**

BRACTEARIA, in natural history, a genus of tales, composed of small plates in form of spangles, each plate being either very thin, or divisible into very thin ones.

BRADS, among artificers, a kind of nails used in building, which have no spreading heads, as other nails have. They are distinguished, by ironmongers, by six names, as joiners-brads, flooring-brads, batten-brads, bill-brads, or quarter-heads, &c. Joiners brads are for hard wainscot, batten-brads for soft wainscot; bill-brads are used when a floor is laid in haste, or for shallow joists subject to warp. See the article **NAIL.**

BRADYPUS, in zoology, a genus of quadrupeds, of the order of the anthropomorpha of Linnaeus, otherwise called *ignavi*, and in English, the sloath; the characters of which are, that its feet have no great toe, and are made for climbing. See the article **ANTHROPOMORPHA.**

Of this genus there are two species. 1. The American sloath, with a short tail, and only three toes on each foot. 2. The Ceylon sloath, with only two toes on each foot, and no tail.

BRAGGET, a kind of drink made of malt, honey, and spices, much used in Wales.

BRAILS, in the marine, ropes fastened in different places on the hinder, or after-ridge of the mizen, to gather it up to the mast in order for furling, when it is not required to be used.

BRAILS are likewise a general name given to all the ropes which haul up, or collect to their yards, the bottoms, edges, and lower- corners of the other great sails, for the more ready furling them; and this drawing together is called brailing them up, or hauling them up in the brails. Plate XXII. fig. 1. in the lower part represents some part of the sail B, hauled up in the brails.

BRAIN, in anatomy, a name given to all that mass which fills the cavity of the cranium, and which is immediately surrounded by two membranes, called meninges by the Greeks, and matres by other ancients, because they were commonly of opinion that these membranes were the origin, and, as it were, the mother of all the other membranes of the body.

This general mass is divided into three particular portions; the cerebrum, or brain, properly so called; the cerebellum, and medulla oblongata. To these three parts contained within the cranium, a fourth is added, which fills the great canal of the spina dorsa by the name of medulla spinalis, being a continuation of the medulla oblongata.

The meninges, or membranes, are two in number, one of which is very strong, and lies contiguous to the cranium; the other is very thin, and immediately touches the brain. The first is named *dura mater*; the second *pia mater*, which is again divided into two, the external lamina being termed *arachnoides*, and the internal retaining the common name of *pia mater*. See the articles *Dura MATER* and *Pia MATER*.

The cerebrum, properly so called, is a kind of medullary mass, of a moderate consistence, and of a greyish colour on the outer surface, filling all the superior portion of the cavity of the cranium, or that portion which lies above the transverse septum. The upper part of the cerebrum is of an oval figure, like half an egg cut lengthwise, or rather like two quarters of an egg cut lengthwise, and parted a little from each other. It is flatter on the lower part, each lateral half of which is divided into three eminences, called lobes, one anterior, one middle, and one posterior.

The substance of the cerebrum is of two kinds, distinguished by two different colours; one part of it, which is the softer, being of a greyish or ash-colour; the other, which is more solid, very white. The ash-coloured substance lies chiefly on the outer-part of the cerebrum, like a kind of cortex; from whence it has been named *substantia corticalis* or *cinerea*. The white substance occupies the inner part, and is named *substantia medullaris*, or simply *substantia alba*.

The cerebrum is divided into two lateral portions, separated by the falx, or great longitudinal septum of the dura mater. They are generally termed hemispheres; but they are more like quarters of an oblong spheroid. Each of these portions is divided into two extremities, one anterior, and one posterior, which are termed the lobes of the cerebrum, between which there is a large inferior protuberance which goes by the same name; so that in each hemisphere there are three lobes, one anterior, one middle, and one posterior.

The anterior lobes lie upon those parts of the os frontis which contribute to the formation of the orbits and of the frontal sinuses, commonly called the anterior fossæ of the basis cranii. The posterior lobes lie on the transverse septum; and the middle lobes in the middle or lateral fossæ of the basis cranii.

Each lateral portion of the cerebrum has three sides, one superior, which is convex; one inferior, which is uneven; and one lateral, which is flat; and turned to the falx. Through the whole surface of these three sides we see inequalities or windings like the circumvolutions of the intestines, formed by waving streaks or furrows very deep and narrow, into which the septa, or duplicatures of the pia mater, insinuate themselves, and thereby separate these circumvolutions from each other.

Near the surface of the cerebrum, these circumvolutions are at some distance from each other, representing serpentine ridges; and in the interstices between them, the superficial veins of the cerebrum are lodged, between the two laminæ of the pia mater, by an infinite number of very fine vascular filaments, as may be seen by pulling the circumvolutions a little asunder with the fingers.

When they are cut transversely, we observe that the *substantia alba* lies in the middle of each circumvolution; so that there is the same number of internal medullary circumvolutions as of external cortical ones; the first representing white laminæ invested by others of an ash-colour; but the cortical substance is in many places thicker than the medullary.

The anterior and middle lobes of the cerebrum on each side are parted by a deep narrow sulcus, which ascends obliquely backward, from the temporal ala of the os sphenoides to near the middle of the os parietale; and the two sides of this division have each their particular ridges and circumvolutions, which gives a very great extent to the cortical substance. This sulcus is termed *fissura magna silvii*, or simply *fissura cerebri*.

The corpus callosum is a white convex body, being a middle portion of the medullary substance, whose surface is covered by the pia mater. Along the middle of its surface, from one end to another, there is a kind of raphæ formed by a particular intertexture of fibres, which

cross

cross each other. After its uniting with the cortical substance, a medullary arch or vault of an oval figure is formed.

Under this arch are two lateral and shallow cavities, separated by a transparent medullary septum; and generally called the anterior superior ventricles of the cerebrum.

The above transparent partition is generally called the septum lucidum, and lies directly under the raphe or suture of the corpus callosum, of which it is a continuation.

The septum lucidum is united by its lower part to the anterior portion of that medullary body improperly called the fornix, with three pillars; because it is thought to bear some resemblance to the arches of ancient vaults.

The fornix being cut off and inverted, or quite removed, we first perceive a vascular web, called plexus choroides, and several eminences more or less covered by the expansion of that plexus. There are four pairs of eminences, which follow each other very regularly, two large and two small. The first pair of larger eminences are named corpora striata, from their having a great number of white and ash-coloured streaks alternately disposed thro' their substance; and the second pair, thalami nervorum opticom, because these nerves arise chiefly from them. The four small eminences are closely united together, the anterior being called nates, and the posterior testes; though it would be better to call them simply, anterior and posterior tubercles.

Immediately before these tubercles, there is a single eminence called glandula pinealis, a small, soft, greyish body, about the size of an ordinary pea, irregularly round, and sometimes of the figure of a pine apple. This gland, which Des Cartes will have to be the seat of the soul, has been often found to contain gravel.

Between the basis of the anterior pillar of the fornix, and the anterior part of the union of the optic thalami, lies a cavity or fossula, called infundibulum. It runs down towards the basis of the cerebrum, contracting gradually, and terminates by a membranous canal in a fossil body, situated in the sella sphenoidalis, named glandula pituitaria. The infundibulum opens above, immediately before the optic thalami, by an oval hole, called foramen commune anterius, and consequently communicates with the lateral ventricles.

The cerebellum is contained under the transverse septum of the dura mater. It is broader laterally than on the fore or back-sides, flatted on the upper-side, and gently inclined both ways, answerable to the septum, which serves it as a kind of tent or ceiling. On the lower-side it is rounder, and on the back-side divided into two lobes, separated by the occipital septum of the dura mater.

It is made up, like the cerebrum, of two substances; but it has no circumsolutions on its surface. Its sulci are pretty deep, and disposed in such a manner as to form that flat strata, more or less horizontal, between which the internal lamina of the pia mater insinuates itself by a number of septa, equal to that of the strata.

Under the transverse septum, it is covered by a vascular texture, which communicates with the plexus choroides. It has two middle eminences called appendices vermiformes, one anterior and superior which is turned forward, the other posterior and inferior which goes backward. There are likewise two lateral appendices, both turned outward. They are termed vermiformes, from their resemblance to a large portion of an earth-worm.

Besides the division of the cerebellum into lateral portions, or into two lobes, each of these lobes seems to me likewise subdivided into three protuberances, one anterior, one middle or lateral, and one posterior; but they are not in all subjects equally distinguished either by their convexity or limits; but they may always be distinguished by the direction of their strata, those of the middle and anterior protuberances being less transverse than in the posterior.

When we separate the two lateral portions or lobes, having first made a pretty deep incision, we discover first of all the posterior portion of the medulla oblongata; and in the posterior surface of this portion, from the tubercula quadrigemina, all the way to the posterior notch of the body of the cerebellum, we observe an oblong cavity, which terminates backward, like the point of a writing pen. This cavity is called the fourth ventricle.

The medulla oblongata is a medullary substance, situated from before backward, in the middle part of the basis of the cerebrum and cerebellum, without any discontinuation, between the lateral parts of both these bases; and therefore it may be looked upon as one middle medullary basis, common to both cerebrum and cerebellum, by the reciprocal continuity of their medullary substances, through the great notch in the transverse septum of the dura mater, which common basis lies immediately on that portion of the dura mater which lines the basis of the cranium. The medulla oblongata is therefore justly esteemed to be a third general part of the whole mass of the brain, or as the common production or united elongation of the whole medullary substance of the cerebrum and cerebellum.

The lower side of the medulla oblongata, in an inverted situation, presents to our view several parts, which are in general either medullary productions, trunks of nerves, or trunks of blood-vessels.

The chief medullary productions are these :
the

the large or anterior branches of the medullary oblongata, which have likewise been named *crura anteriora*, *femora* and *brachia medullæ oblongatæ*, and *pedunculi cerebri*; the transverse protuberance, called also *processus annularis* or *pons varolii*; the small or posterior branches, called *pedunculus cerebelli*, or *crura posteriora medullæ oblongatæ*; the extremity or cauda of the medulla oblongata, with two pairs of tubercles, one of which is named *corpora olivaria*, the other *corpora pyramidalia*: and to all these productions we must add a production of the infundibulum and two medullary papillæ.

We must observe in general concerning the eminences of the medulla oblongata, that those which are medullary on their outlides or surfaces, are interiorly either entirely cortical, or partly cortical and partly medullary, or formed by a singular mixture of these two substances.

From this common portion of the cerebrum and cerebellum, arise almost all the nerves which go out of the cranium through the different foramina by which its basis is perforated. It likewise produces the medulla spinalis, which is no more than a common elongation of the cerebrum and cerebellum, and of their different substances; and therefore the medulla oblongata may be justly said to be the first origin or primitive of all the nerves which go out through the *spina dorsalis*, and consequently of all the nerves of the human body. See the articles *MEDULLA SPINALIS*, and *NERVE*. *Winflow's Anatomy*.

BRAKE, in the marine, the handle or lever of a common pump, by which it is wrought: it is fitted to go between two ears at the upper part of the pump, through both of which, and a hole in the brake, is thrust an iron pin, upon which the lever rests, as it draws up the water through the tube. See the article *PUMP*.

BRAKES, a name by which the fern is called in several parts of England. See the article *FERN*.

BRAMBLE, in botany; see the article *RUBUS*.

BRAMBLE-NET, otherwise called *halleri*, is a net to catch birds in, of several sizes; the great meshes must be four inches square; those of the least size are three or four inches square; and those of the biggest five. In the depth, they should not be above three or four inches; but as for the length, they may be enlarged at pleasure; the shortest being eighteen feet long.

BRAMINS, the name of the priests among the idolatrous Indians, the successors of the ancient Brachmans. See the article *BRACHMANS*.

BRAN, the skins or husks of corn, especially wheat ground, separated from the flour by a sieve or boulder.

BRANCA URSINA, bears-beech, in botany. See the article *ACANTHUS*.

BRANCH, in botany, an arm of a tree, or a part which, sprouting out from the trunk, helps

to form the head or crown thereof. The branches of a tree bear a resemblance to the exterior members or limbs of animals, and are of the same nature with the trunk; for their inward parts consist of a multitude of tubes, which are also provided with a number of small glands, veins, and muscles, interspersed here and there, where the sap coming from the first canal is rendered much more delicate; often branches rise without order and in confusion from the trunk, as in the elm, oak, and others. With some plants they are more elegant and regularly placed, as in the fir-trees, &c. Branches are distinguished into various kinds: 1st, Wood branches, which are those that form the shape of the tree: 2dly, Fruit branches, which are slenderer than the wood branches, and have their eyes near to each other, and large, by which the fruit buds are formed: 3dly, Luxuriant branches, which are such as shoot out from the large wood branches: 4thly, Irregular branches, such as are small and confused: 5thly, Spurious wood branches, such as come contrary to the order of nature. The distinguishing marks of good branches are, that the eyes in the whole extent be thick, well-fed, and close to each other. The good strong branches are employed in producing yearly on their extremities other new branches, some strong and others weak. The good weak branches are such as are well placed, and being of a mean thickness and length, may be able to produce speedily beautiful and good fruit. The distinguishing marks of bad branches are, when the lower part of the eyes are flat, ill fed, and hardly formed, and at a large distance from each other. For the method of managing branches, see the article *PRUNING*.

BRANCH, in fortification. See *BOYAU*.

BRANCH is likewise a term used in genealogy and anatomy. Thus we say, the branch of a family, the branch of an artery, the branch of a vein.

BRANCHES of a Bridle, in the manege, are two pieces of iron bended, which in the interval, between the one and the other, bear the bit-mouth, the cross-chains, and the curb; so that on one end they answer to the head-stall, and on the other to the reins, in order to keep the horse's head in subjection.

BRANCHES of Ogives, in architecture, are the arches of Gothic vaults. These arches traversing from one angle to another diagonal wise, form a cross between the other arches, which make the sides of the square, of which the arches are diagonals.

BRANCH of a Trench. See *BOYAU*.

BRANCH of a Mine. See *GALLERY*.

BRANCH-STAND, with falconers, a term used to signify the making a hawk leap from tree to tree, till the dog springs the game.

BRANCHER, among sportsmen, a young hawk,

hawk, newly taken out of the nest, that can hop from bough to bough.

BRANCHERY, in the anatomy of plants, denotes the ramifications of the succiferous vessels dispersed through the parenchyma, or pulpy parts of fruits.

The main branches are usually twenty in number; one half, or fifteen, being distributed over the parenchyma, and the rest, running from the stalk in a straight line, meet the former at the cork or shoot of the flower: to these last the coats of the kernels are fastened.

BRANCHIÆ, GILLS, in the anatomy of fishes, the parts corresponding to the lungs of land-animals, by which fishes take in and throw out again a certain quantity of water, impregnated with air. All fishes, except the cetaceous ones and the petromyzon, are furnished with these organs of respiration; which are always eight in number; four on each side the throat; that next the heart is always the least, the rest increasing in order as they stand near the head of the fish.

Each of these gills is composed of a bony lamina, in form of a semicircle, for the most part; and on its convex side stand the leaves or lamellæ, like so many sickles. The whole convex part of the lamellæ is beset with hairs, which are longest near the base, and decrease gradually as they approach towards the point. There are also hairs on the concave side of the lamellæ, but shorter than the others, and continued only to its middle.

The convex side of one lamina is fitted into the concave side of the next superior one; and all of them are connected together by means of a membrane, which reaches from their base half way their height, where it grows thicker, and in some measure resembles a rope. The rest of the lamina is free, and terminates in a very fine and flexible point.

As to the use of these gills, they seem to be designed to receive the blood protruded from the heart into the aorta, and convey it into the extremities of the lamellæ; from whence being returned by veins, it is distributed over the body of the fish.

BRANCHIARUM FORAMINA, Apertures of the Gills. In most fishes there is only one aperture; in the cartilaginous ones, these apertures are ten in number, five on each side; and in the petromyzon or lamprey, there are no less than fourteen of these apertures, seven on each side.

As to the cetaceous fishes, they have no aperture of this kind; and the reason seems to be, because they are furnished with lungs.

BRANCHIDÆ, in Grecian antiquity, priests of the temple of Apollo, which was at Didymus in Ionia, a province of Lesser Asia, towards the Ægean sea, upon the frontiers of Caria. They opened to Xerxes the temple of Apollo, the riches whereof he took away: after which, thinking it

unsafe to stay in Greece, they fled to Sagdiana, on the other side of the Caspian sea, upon the frontiers of Persia, where they built a city, called by their own name: but they did not escape the punishment of their crime; for Alexander the Great, having conquered Darius, king of Persia, and being informed of their treachery, put them all to the sword, and razed their city; thus punishing the impiety of the fathers in the posterity.

BRANDY, a spirituous and inflammable liquor, extracted from wine and other liquors by distillation, which is most generally performed by the common alembic; but sometimes also in balneum maria. See **DISTILLATION**.

The chief use of brandy is as a drink, particularly in the northern countries, among the negroes of Guinea, who will sell one another for some bottles of brandy, and among the savages of Canada, who are extremely fond of it. Brandy is also used in medicine, to strengthen the nerves; and in dying, rectified spirits of wine being reckoned by the dyers among the non-colouring drugs.

Method of colouring BRANDY. All brandies, when first made, are as clear as water, and grow higher coloured by long keeping: however, they are artfully made of any colour several ways. To make a light straw-colour, use turmeric, or a little treacle: but the best way is to give it a colour or tincture with a little burnt sugar, made to a consistency; or syrup of elder-berries may be used, which gives an admirable colour, and may be made deeper or lighter, according to the quantity you put in.

Besides the brandy made of wine, there is some also made of beer, cyder, syrups, sugar, molasses, fruit, grain, &c. however, these are not properly called brandy; but go under the general denomination of spirits. See the articles **RUM, ARRACK, &c.**

Wine brandy made in France, is esteemed the best in Europe. They make it wherever they make wine; and for that purpose, use wine that is prickled, rather than good wine.

BRASIDIA, an anniversary solemnity at Sparta, in memory of Brasidas, a Lacedæmonian captain, famous for his achievements at Methone, Pylos, and Amphipolis. It was celebrated with sacrifices and games, wherein none were permitted to contend, but free-born Spartans. Whoever neglected to be present at the solemnity, was fined.

BRAZIL, or BRAZIL, in natural history, is a red wood, brought from the province of that name in South-America. There are different sorts of it, distinguished by the names of Fernambouc, St. Martha, &c. What differences there are in the trees we know not: the woods, brought to us, differ little otherwise than as different parts of one log, some pieces being richer in colour than others.

This wood is called, by Caspar Bauhipe, bastard red-fauanders, *Pseudosant alum rubrum sive arbor Brazilia*. Many have confounded it with the true red-fauanders: the college of Brussels, in their account of that wood, have plainly mistaken the Brazil for it: however the two trees may be allied in their botanic characters, the woods, chemically considered, are very obviously different; Brazil wood readily giving out its red colour to water, whilst faunders gives no red tinge to any aqueous liquor. The watery tincture of Brazil, however, is not quite so deep as that made in rectified spirit of wine, or in volatile alkaline spirits.

The spirituous tincture stains warm marble of a purplish red, which, upon increasing the heat, becomes violet. Mr. du Fay informs us, in a paper upon this subject in the French Memoirs, that if the stained marble be covered with wax, and considerably heated, it changes through all the shades of brown, and fixes at last in a chocolate colour.

The colour of the watery decoction is heightened by alum, and inclined to a crimson. A decoction made with alum, in the proportion of about one part of the salt to four of the wood, yields upon adding alkaline ley or volatile spirits, a kind of crimson lake verging a little to violet.

Solution of tin in aqua-fortis, added to the decoction, throws down a much finer coloured precipitate, little inferior in beauty to carmine. This experiment, first communicated in the *Acta Naturæ Curiosorum*, has been several times repeated with success. The quantity of lake is largest when alum is used in making the decoction; but the colour is much finer without it.

BRASS, or, as the French call it, YELLOW-COPPER, is a factitious metal, made of copper and lapis calaminaris.

The method of preparing it is as follows: The lapis, having been calcined and ground fine as flour, is mixed with fine charcoal, and incorporated, by means of water, into a mass: this being done, about seven pounds of lapis calaminaris is put into a melting pot that will contain about a gallon, and over that about five pounds of copper; this pot is let down into a wind furnace, where it remains for eleven hours, in which time it is converted into brass. The metal then is cast, either into plates or lumps; forty-five pounds of crude lapis calaminaris will produce thirty pounds when calcined or burned. Sometimes brassy-thruff is used instead of copper; but that is not always to be procured in quantities sufficient, it being no other than a collection of old brass.

Pure brass is not malleable, unless when it is hot; for when it is cold it will break; and after it has been melted twice, it will be no longer in a condition to bear the hammer at all: but in order to render it capable of being wrought, they put seven

pounds of lead to an hundred weight of brass, which renders it more soft and pliable.

The best proportion for brass-guns is said to be a thousand pounds of copper, nine hundred pounds of tin, and six hundred pounds of brass, in eleven or twelve thousand weight of metal.

The best brass guns are made of malleable metal, not of pure copper and calamine alone; but worse metals are used to make it run closer and sounder, as lead and pot-metal. See CANNON.

Brass may be cleaned, first, by rubbing it with a cloth dipped in equal quantities of aqua-fortis and common water; then with an oily cloth, and lastly, with a dry one dipped in lapis calaminaris.

Brass is tinged of a gold colour, first, by burning, then dissolving it in aqua-fortis, and lastly, reducing it to its metalline state. It may be whitened by heating it red-hot, and quenching it in water distilled from sal ammoniac and egg-shells. It is silvered, or coloured superficially white, by rubbing it with balls made of silver dissolved in aqua-fortis, with powder of white tartar, sufficient to absorb all the moisture thereof.

Corinthian BRASS has been famous in antiquity, and is a mixture of gold, silver, and copper. L. Mummius having sacked and burned the city of Corinth, 146 years before Christ, it is said this metal was formed from the immense quantities of gold, silver, and copper, wherewith that city abounded, thus melted and run together by the violence of the conflagration.

BRASS-COLOUR, one prepared by the braziers and colourmen to imitate brass. There are two sorts of it, the red brass, or bronze, and the yellow or gilt brass; the latter is made only of copper-filings, the smallest and brightest that can be found; with the former they mix some red ochre, finely pulverized: they are both used with varnish.

BRASSICA, in botany; see the article CABBAGE.

BRASSICAVIT, or BRACHICAVIT, in the manege, is a horse whose fore legs are naturally bended archwise: being so called by way of distinction from an arched horse, whose legs are bowed by hard labour.

BRAULS, Indian cloths with blue and white stripes. They are otherwise called turbans, because they serve to cover those ornaments of the head, particularly on the coast of Africa.

BRAURONIA, in Grecian antiquity, a festival in honour of Diana, surnamed Brauronia, from its having been observed at Brauron, an Athenian borough.

BRAWN, the flesh of a boar foused or pickled; for which end the boar should be old, because the older he is, the more horny will the brawn be.

The method of preparing brawn is as follows: The boar being killed, it is the stitches only, with-

out the legs, that are made brawn; the bones of which are to be taken out, and then the flesh sprinkled with salt, and laid in a tray, that the blood may drain off: then it is to be salted a little, and rolled up as hard as possible. The length of the collar of brawn should be as much as one side of the boar will bear; so that when rolled up, it will be nine or ten inches diameter.

The collar being thus rolled up, is to be boiled in a copper, or large kettle, till it is so tender that you can run a straw through it; then set it by, till it is thorough cold, and put it into the following pickle. To every gallon of water, put a handful or two of salt, and as much wheat bran: boil them together, then drain the bran as clear as you can from the liquor; and when the liquor is quite cold, put the brawn into it.

BRAZING, the folding or joining two pieces of iron together, by means of thin plates of brads, melted between the pieces that are to be joined. If the work be very fine, as when two leaves of a broken saw are to be brazed together, they cover it with pulverized borax, melted with water, that it may incorporate with the brads powder, which is added to it: the piece is then exposed to the fire without touching the coals, and heated till the brads is seen to run.

BRAZING is also the joining two pieces of iron together by heating them hot, the one upon the other, which is used for large pieces by farriers, &c.

BREACH, in fortification, a gap made in any part of the works of a town by the cannon or mines of the besiegers, in order to make an attack upon the place.

A practical breach is that where men may mount, and make a lodgment, and ought to be fifteen or twenty feet wide.

BREACH, in a legal sense, is where a person breaks through the conditions of a bond or covenant, on an action upon which the breach must be assigned: nor must the assignment be general; it must be particular; as in an action of covenant for repairing houses, it ought to be assigned particularly what the want of reparation really is; and in such certain manner that the defendant may take an issue.

BREAD, *Panis*, a mass of dough kneaded and baked in an oven.

We find bread sometimes made of rye, of oats, and of barley; but that prepared from wheat is by far the most wholesome. In several parts of Asia, Africa, and America, they make bread of maize, or Indian corn; and in some parts the Americans make bread of the cassava-root. See *CASSAVA*.

BREADTH, in geometry, one of the three dimensions of bodies, and which, multiplied into the length, produces a surface.

BREAKERS, a name given by sailors to the

waves, which breaking violently over rocks immediately under the surface of the water, cover that part of the sea with foam: they are otherwise to be distinguished by a hoarse and terrible roaring, continued with a sound very different from what they have in the offing, or at a distance from the land.

When a ship is unhappily driven amongst these, it is hardly possible she can be saved, as every billow that heaves her upwards, dashes her down with additional force, when it breaks amongst the rocks or sands: we have ourselves seen the surges break over the mast head in such a situation, whither the remainder of an unfortunate crew had sought a last refuge.

BREAKING-BULK, in the marine, unloading the first part of a ship's cargo.

BREAK-WATER, the hull or lower frame of some old ship or vessel, sunk at the entrance of a small harbour, to break off the force of the waves from the vessels which are moored within it.

BREAK-WATER is likewise a small buoy fastened to a large one in the water, when the buoy-rope of the latter is not long enough to reach from the anchor at the bottom to the surface of the water: the use of this break-water is to shew where the buoy swims. See the article *BUOY*.

BREAM, *Brama*, in ichthyology, the name of a fish, of which there are two sorts, one found in the fresh, and the other in the salt water. The former is the cyprinus, and has all its fins black; and the latter the reddish sparus, having eleven parallel and gold coloured lines on each side.

BREAMING, in the marine, the act of burning off the filth, such as grass, ooze, or shells, from a ship's bottom, that had gathered to it in a voyage, or by lying long in a harbour.

BREAMING is performed by holding kindled furze or faggots to the ship's bottom: the flame immediately incorporating with the pitch, sulphur, &c. that had formerly covered the bottom, directly loosens and throws off whatever excrement may have adhered to it: after this cleansing, it is covered a-new with a composition of tallow, sulphur, turpentine, &c. and this not only makes the bottom smooth and slippery, so that it more readily divides the fluid, but greatly contributes to poison the worms that eat through a ship's planks, as long it remains there. See *CAREEN*, *DOCK*.

BREAST, *Pectus*, in anatomy, the fore-part of the thorax. See *THORAX*.

BREASTS, *Mammæ*, in anatomy; see the article *MAMMÆ*.

BREAST-FAST, in the marine, a hawser, or large rope that confines a ship to a wharf, or other place sideways.

BREAST-HOOKS, in naval architecture, strong crooked pieces of timber fayed a-cross the inside of a ship's bows, or fore-part, and bolted to the stem and foremost timbers. See *CANT-TIMBERS*, *STEM*.

The

The breast-hooks are the principal support of the ship forward, as they bear all the shock of resistance which she receives in dividing the fluid.

BREAST-PLATE, in antiquity, a piece of armour worn to defend the breast, originally believed to be made of hides, or hemp twisted into small cords; but afterwards made of brass, iron, or other metals, which were sometimes so exquisitely hardened, as to be proof against the greatest force.

BREAST-PLATE, in the manege, the strap of leather that runs from one side of the saddle to the other, over the horse's breast, in order to keep the saddle tight, and hinder it from sliding backwards.

BREAST-PLOUGH, one so fashioned that a man may shove it before him.

BREAST-WORK, the same with parapet. See the article PARAPET.

BREECH of a great Gun, or Cannon, the end next the touch-hole.

BREECHING, in the marine, a thick rope used to secure the cannon of a ship of war, and prevent them from recoiling too much in the time of battle.

It is fixed by fastening the middle part of it to the cascabel, or hindmost knob of the cannon, called by seamen the pomiglion; afterwards the two ends of it are inserted through two strong iron rings in the outsidcs of the carriage, and fastened to eye-bolts in the ship's side: the breeching is of sufficient length to let the muzzle of the cannon come within the ship's side.

BREEZE, a shifting wind that blows from sea or land for some certain hours in the day or night; common in Africa, and some parts of the East and West-Indies.

The sea-breeze is only sensible near the coasts; it commonly rises in the morning, about nine, proceeding slowly in a fine small black curl on the water, towards the shore; it increases gradually till twelve, and dies about five. Upon its ceasing, the land-breeze commences, which increases till twelve at night, and is succeeded in the morning by the sea-breeze again.

BREEZE, in brick-making, small ashes and cinders, sometimes made use of instead of coals, for the burning of bricks: but as this does not so well answer the end, the use of it is prohibited by 12 Geo. I. cap. xxxv.

BREGMA, in anatomy, the same with sinciput. See SINCIPUT.

The bregma consists of two bones, which are bones of the cranium, called ossa parietalia.

BRENT-GOOSE, a species of goose with a black neck and a white collar round; usually confounded with the barnacle, though in reality a distinct species.

It is a little larger than the common duck, and is described by authors under the name of *anas forquata*.

BREST, or BREAST, in architecture, a term sometimes used for the member of a column, more usually called torus. See the article TORUS.

BREST-SUMMERS, in timber buildings, are pieces in the outward parts thereof, into which the girders are framed: this in the ground-floor is called a cill; and in the garret-floor a beam.

As to their size, it is the same with that of girders. See the article GIRDERS.

BREVE, in law, is any writ directed to the chancellor, judges, sheriffs, or other officers, whereby a person is summoned, or attached, to answer in the king's courts, &c.

BREVE PERQUIRERE, the purchasing of a writ or licence for trial in the king's courts: whence comes the present usage of paying six shillings and eight-pence fine to the king in suit, for money due on bond, where the debt is forty pounds, and of ten shillings where it is a hundred pounds, &c.

BREVE DE RECTO is a writ of right, or licence, for a person ejected to sue for the possession of the estate detained from him.

BREVE, in music, a note or character of time, in the form of a diamond, or square, without any tail, and equivalent to two measures, or semi-breves.

BREVE, or BREVIS, in grammar: syllables are distinguished into longs and breves, according as they are pronounced quicker or more slow.

BREVIER, among printers, a small kind of type, or letter, between nonpareil and bourgeois.

BREVIS, in anatomy, an appellation given to several muscles, on account of their shortness. Thus,

BREVIS CUBITI, in anatomy, is a muscle that rises from the superior and posterior part of the humerus, and by joining its fleshy fibres with the brachæus externus and longus, and becoming tendinous, covers the elbow, and is inserted into the olecranium, to extend the arm.

BREVIS RADII, a muscle which comes from the external and upper part of the ulna, and passing round the radius, is inserted into its upper and fore part, below the tendon of the biceps: this and the longus radii are called the supinators, their office being to turn the palm upwards.

BREVIS PALMARIS lies under the aponeurosis of the palmaris, and arises from the bone of the metacarpus that sustains the little finger, and from that bone of the carpus which lies above the rest: it goes transversely, and is inserted into the eighth bone of the carpus: it assists in making the palm of the hand concave.

BREVITY, in matters of style, is a perfection of discourse, whereby all superfluous words are rejected, and only such as are absolutely necessary used. However, as brevity is apt to degenerate into obscurity, it is a less fault to say too much than too little.

BREW-HOUSE, a building adapted to the brewing, &c. of malt liquors.

In order to erect a large or public brew-house to the best advantage, several circumstances should be carefully observed. 1. That three fides in four of the upper-part, or second floor, be built with wooden battens about three inches broad, and two thick, that a sufficient quantity of air may be admitted to the backs or coolers. 2. That the coppers be erected of a proper height above the mashing-flage, that the hot water may be conveyed by means of cocks into the mash-tuns, and the worts into the coolers. 3. That the fire-places of the coppers be very near each other, that one flooker, or person who looks after the fire, may attend all. 4. That the yard for coals be as near as possible to the fire-places of the copper. 5. That the malt be ground near the mash-tuns, and the mill erected high enough that the malt may be conveyed from the mill immediately into the mash-tuns, by means of a square wooden spout or gutter. 6. That the upper backs be not erected above thirty-three feet above the reservoir of water, that being the greatest height water can be raised by means of a common single pump. 7. That the pumps which raise the water, or liquor, as the brewers call it, out of the reservoir into the water-backs, and also those which raise the worts out of the jack-back into the coppers, be placed so that they may be worked by the horse-mill which grinds the malt.

BREWING, the operation of preparing ale, or beer, from malt. The usual process of brewing is as follows: the ingredients being ready, the water must be made to boil very speedily, and while boiling with the greatest violence the fire must be immediately damped, or put out; when the height of the steam is over, the water is put into the mashing-tun to wet the malt; then so much being poured out as to make it of a consistence stiff enough to be rowed up, let it stand thus a quarter of an hour, after which another quantity of the water is added, and rowed up as before; at last the full quantity of water is poured upon it, and that in proportion as the liquor is intended to be strong or weak: this part of the operation is called mashing. Afterwards the whole may be left to stand two or three hours, more or less, according to the strength of the wort, or the difference of the weather; then let it run into the receiver, and mash again for a second wort in the same manner as for the first, only the water must be cooler, and must not stand above half the time.

The two worts being mixed together, the quantity of hops that is designed may be added thereto, and the liquor put into the copper, which being closely covered up, let it boil gently for the space of an hour or two; then let the liquor into the receiver, and the hops strained from it into the coolers.

When cool, the yeast is applied; which done,

it is left to work or ferment, till it be fit to tun up.

For small beer there must be a third mashing; the water must be near cold, and to stand not above three quarters of an hour; to be hopped and boiled at discretion.

For double ale, or beer, the two liquors coming from the two first mashings must be used as liquor for a third mashing of fresh malt. For fine ale, the liquor thus brewed is farther prepared with molasses: instead of yeast, or baum, some use Castile soap, others flour and eggs, others an essential oil of barley, others a quintessence of malt, others of wine, and others the sal panacristus.

In ordering vessels for the preservation of beer, they must not at one time be scalded, and at another washed with cold water: some rub the vessels with hop-leaves, that come out of the wort, and so rinse them again; then being dried in the air, and headed, they take a long piece of canvas, and dipping it in brimstone make matches thereof, and with a few coriander-seeds set fire thereto: others opening the bung let the match burn in the vessel, keeping in as much as they can of the sulphureous fume, by laying the bung lightly on, and when the match is burnt, they stop all close for a little time; then being opened, and coming to the air, the cask is found to be as sweet as a violet.

BREWING, in the sea-language, the appearance of a collection of black and gloomy clouds gradually arising from a particular part of the hemisphere, as the fore-runner of a squall or storm.

BREYNIA, in botany, a genus of polyandrous plants, classed by Linnæus with the capparidæ. There are two species in this genus, which are both natives of the warm parts of America; but being impatient of cold, they must be kept in a hot-house in this climate to preserve them. For their generic characters, see the article **CAPPARIS**.

BRIAR, in botany, a species of the rose. See the article **ROSE**.

BRIBERY, in common law, is when a person in judicial places, takes a gift or reward of any person who has business before him, for his doing his office, or by colour of his office, except the king only, unless it be meat and drink.

BRICK, a fat reddish earth, formed into long squares, four inches broad, and eight or nine long, by means of a wooden mould, and then baked or burnt in a kiln, to serve the purposes of building.

Among us they are various, according to their various forms, dimensions, uses, method of making, &c. the principal of which are, compass bricks, of a circular form, used in staining of walls: concave, or hollow bricks, on one side flat like a common brick, on the other hollowed, and used for conveyance of water: feather-edged bricks, which

which are like common statute bricks, only thinner on one edge than the other, and used for penning up the brick pannels in timber buildings: cogging bricks are used for making the indented works under the coping of walls built with great bricks: coping bricks, formed on purpose for coping of walls: Dutch or Flemish bricks, used to pave yards, or stables, and for soap-boilers vaults and cisterns: clinkers, such bricks as are glazed by the heat of the fire in making: sandal or samel bricks are such as lie outmost in a kiln, or clamp, and consequently are soft and useless, as not being thoroughly burnt: great bricks are those twelve inches long, six broad, and three thick, used to build fence walls: plaster or buttress bricks have a notch at one end, half the breadth of the brick; their use is to bind the work which is built of great bricks: statute bricks, or small common bricks, ought, when burnt, to be nine inches long, four and a quarter broad, and two and a half thick; they are commonly used in paving cellars, sinks, hearths, &c.

The Method of burning BRICKS.—Bricks are burnt either in a kiln or clamp. Those that are burnt in a kiln are first set or placed in it, and then the kiln being covered with pieces of bricks, they put in some wood, to dry them with a gentle fire; and this they continue till the bricks are pretty dry, which is known by the smoke's turning from a darkish colour to a transparent smoke: they then leave off putting in wood, and proceed to make ready for burning, which is performed by putting in brush, furze, spray, heath, brake, or fern faggots; but before they put in any faggots, they dam up the mouth or mouths of the kiln with pieces of bricks, which they call shinlog, piled one upon another, and close it up with wet brick-earth, instead of mortar.

The shinlog they make so high, that there is but just room above it to thrust in a faggot; they then proceed to put in more faggots, till the kiln and its arches look white, and the fire appears at the top of the kiln; upon which they slacken the fire for an hour, and let all cool by degrees. This they continue to do alternately, heating and slackening, till the ware be thoroughly burnt, which is usually effected in forty eight hours.

About London they chiefly burn, in clamps, built of the bricks themselves, after the manner of arches in kilns, with a vacancy between each brick, for the fire to play through; but with this difference, that instead of, arching, they span it over by making the bricks project one over another, on both sides of the place, for the wood and coals to lie in till they meet, and are bounded by the bricks at the top, which close all up. The place for the fuel is carried up straight on both sides, till about three feet high; then they almost

fill it up with wood, and over that lay a covering of sea-coal, and then overspan the arch; but they strew sea-coal also over the clamp betwixt all the rows of bricks; lastly, they kindle the wood which gives fire to the coal, and when all is burnt, they then conclude the bricks are sufficiently burnt.

Oil of BRICKS, olive oil imbibed by heated bricks, which are afterwards broken, put into a retort, and the oil again extracted from them by an open fire.

BRICKLAYER, a person who lays bricks in the building of walls, houses, &c.

Tilers and bricklayers were incorporated 10 Eliz. under the name of master and wardens of the society of freemen of the mystery and art of tilers and bricklayers.

BRIDGE, a building either of stone or timber, consisting of one or more arches, erected over a river, canal, or the like, for the conveniency of passing the same.

The parts of a bridge are the piers, the arches, the pavement, or way over for carriages, the foot-way on each side for foot-passengers, the rail or parapet which encloses the whole, and the buttments or end of the bridge on the banks. The building of bridges over rivers is very difficult, on account of the great inconvenience in laying the foundation or building under water.

The requisites that are thought necessary by architects, in bridges, are, that they be well designed, commodious, durable, and suitably decorated. The piers of stone bridges should be equal in number, that there may be one arch in the middle, where commonly the current is strongest: their thickness is not to be less than a sixth part of the span of the arch, nor more than a fourth. They are commonly guarded in front with an angular sterling, or spur, to break the force of the current, though this defence is sometimes turned semicircular. In the ancient bridges it is always a right angle, which has the advantage of being more strong and durable than acute ones.

Among the bridges of antiquity, that built by the emperor Trajan over the Danube was the most magnificent of all the works of this kind. It was erected for the conveniency of sending succours to the Roman legions on the other side the Danube, in case they should be suddenly attacked by the Daci; but demolished by the next successor Hadrian, for demolishing the barbarians, overpowering the guards set to defend it, should, by means of it, pour into Mæsia, and cut off the garrisons there; or rather, as some think, out of envy, as despairing ever to do any thing like it himself. The ruins of it are still seen in the middle of the Danube, near the city Warhel in Hungary. It consisted of twenty arches, each one hundred and fifty feet, from pier to pier, and one hundred and fifty feet high.

high, and the piers fifty feet thick; its whole length was seven furlongs, which is more than four times the length of London-bridge.

In France, the Pont de Garde is a very bold work, the piers being only thirteen feet thick, yet serving to support an immense weight of a triplicated arcade. It joins two mountains, and consists of three bridges one over another, the uppermost of which is an aqueduct.

The bridge at Avignon was begun in the year 1176, and finished in 1188, consisting of eighteen arches, measuring 1340 paces in length, or about 500 fathoms: divers of its arches have since been demolished by the ice, &c. so that only part of it now subsists.

The bridge of St. Esprit is the finest in all France, consisting of nineteen great arches, besides seven smaller ones, the apertures of the arches being from fifteen to twenty fathoms, which makes the length of the bridge upwards of four hundred fathoms. In the two last mentioned bridges there is this remarkable, that they are not straight, but bent, having an angle, whose convexity is turned towards the stream, to break the force thereof. The Pont St. Esprit, Dr. Robinson observes, is bowed in many places, making unequal angles, especially in those parts where the stream is strongest. The great pier in London-bridge, it is said, was intended to serve for a steadying to the whole machine, instead of making an angle, as in the above-mentioned bridges.

The Trajan bridge at Salamanca, over the river Tormus, popularly attributed to the giants, and by some to Hercules, appears rather to be a Roman work, though when and by whom erected, is not known; but it was repaired by Trajan, whose denomination it still bears. It is 1500 feet long, consists of twenty-six arches, each seventy-two feet wide; the piers that sustain them being twenty-three feet thick, and two hundred feet high.

The famous bridge of Venice called the Rialto consists but of one arch, and that a flat or low one, passing for a master-piece of art, being built in 1501, after the design of Michael Angelo: the span of the arch is ninety-eight feet and a half, and its height above the water only twenty-three feet. Poulet also mentions a bridge of a single arch in the city of Munster in Bothnia, much bolder than that of the Rialto at Venice.

But these are nothing to a bridge in China built from one mountain to another, consisting of one single arch 400 cubits long, and 500 cubits high, whence it is called the flying bridge; a figure of it is given in the Philosophical Transactions. Kircher also speaks of a bridge in the same country 360 perches long, without any arch, supported only by 300 pillars.

The longest bridge in England is that over the Trent at Burton, built by Bernard, abbot of Bur-

ton, in the twelfth century; it is all of squared free stone, and lofty, 1545 feet in length, and consisting of 34 arches: yet this comes far short of the wooden bridge over the Drave, which, according to Dr. Brown, is at least five miles long.

Rocheſter-bridge is built after the same method as London, only better, in that the arches are wider: it is 550 feet long, and consists of eleven arches, the biggest of which is more than fifty feet. The bridge at Berwick is an admirable work, begun under queen Elizabeth; it consists of seventeen arches, the largest upwards of eighty feet.

London-bridge formerly consisted of twenty arches; it is 900 feet long, sixty high, and seventy-four broad, had a draw-bridge in the middle, and almost twenty feet aperture in each arch. It was supported by eighteen piers, from thirty-four to twenty-five feet thick, so that the greatest water-way, when the tide was above the sterling, was 450 feet, scarce half the width of the river, and below the sterling was no more than 194 feet. Thus a river 900 feet wide was forced through a channel of 194 feet; which caused the fall of water to be so great as to render the passage of boats and other vessels very dangerous; nor is it much better at present, though lately two arches have been thrown into one.

Among modern bridges that of Westminster, built over the river Thames, may be accounted one of the finest in the world: it is forty-four feet wide, a commodious foot-way being allowed for passengers, on each side, of about seven feet broad, raised above the road allowed for carriages, and paved with broad moor-stones, while the space left between them is sufficient to admit three carriages and two horses to go a-breaſt, without any danger. Its extent from wharf to wharf is 1220 or 1223 feet, being full 300 feet longer than London-bridge. The free water-way under the arches of this bridge is 870 feet, being four times as much as the free water-way left between the sterlings of London-bridge; this disposition, together with the gentleness of the stream, are the chief reasons why no sensible fall of water can ever stop, or, in the least, endanger the smallest boats, in their passage through the arches.

It consists of thirteen large and two small arches, together with fourteen intermediate piers.

Each pier terminates with a salient right angle against either stream: the two middle piers are each seventeen feet wide at the springing of the arch, and contain 3000 cubic feet, or near 200 tons of solid stone; and the others decrease in width equally on each side by one foot.

All the arches of this bridge are semicircular; they all spring from about two feet above low-water mark; the middle arch is seventy-six feet wide, and the others decrease in breadth equally on each side by four feet.

This bridge is built of the best materials, and the size and dispositions of these materials are such, that there is no false bearing, or so much as a false joint in the whole structure; besides that, it is built in a neat and elegant taste, and with such simplicity and grandeur, that, whether viewed from the water, or by the passengers who walk over it, it fills the mind with an agreeable surprise. The semioctangular towers, which form the recesses of the foot-way, the manner of placing the lamps, and the height of the balustrade, are at once the most beautiful, and, in every other respect, the best contrived.

Blackfriars-bridge, by all appearance at present, will be the most complete and noble structure of the kind that ever yet has been erected. The first pile of this bridge was driven June the 7th, 1760, and the first stone was laid October 31, 1760, by Sir Thomas Chitty, Knt. Lord-Mayor, attended by the bridge-committee, with great ceremony.

With regard to the strength of arches, much has lately been said by many able mathematicians. Mr. Simpson tells us, that to obtain a proper idea of the strength of any proposed arch, there are two things that ought principally to be attended to; the one respecting the arch itself, arising from the length and disposition of the voussoirs, or arch-stones, and the other with regard to the thickness and strength of the piers proper for the support of such an arch. For with respect to the former of these considerations, it is manifest, that should the voussoirs happen to be so ill-adapted to the nature of the curve, and the span of the arch, as to have a tendency to open and slip out of their places with a force greater than can be balanced, or taken away by the roughness of the stone, assisted by the cement, &c. used on those occasions, which is far from being impossible; such an arch, on striking the centers, must unavoidably fall, however strong its abutments may be. On the other hand, however well an arch may be contrived and proportioned in itself, its ruin will be equally certain and inevitable, if the piers on which it is placed should not have a sufficient degree of strength to resist the lateral pressure.

When the voussoirs are all supposed of an equal length, it is well known that the catenarian arch is that, wherein all the arch-stones will stand in equilibrium among themselves, without any the least assistance from their roughness or adhesion. But arches of this kind (not to insist here on the difficulty of forming the centers necessary to their construction) are not altogether proper for bridges over navigable rivers, because their spring is not at right angles to the horizon, but considerably inclined, so as to diminish the quantity of the water-way, and to obstruct the passage of vessels under the bridge, especially near the time of high-water.

Arches that take their spring from low-water mark, in a direction perpendicular to the horizon, are; beyond all doubt, the best adapted to the purposes of navigation: but in arches of this sort, (and such are the semi-circular and semi-elliptical) the arch-stones about the haunches have a strong tendency to quit their places, and force their way outwards, from the lateral pressure of the upper-part of the arch. A part of this effort is indeed taken away or balanced by the weight of the materials laid upon the arch, in order to the forming the road over the bridge; but to have an exact equilibrium of the arch-stones in these cases, their lengths from the key downwards ought to be increased in a certain proportion depending on the particular nature of the proposed extradoses of every two contiguous arches, that they may meet each other above the center of the piers, so as to render the spandrels intirely solid quite up to high-water mark: and it is certain that an arch so constructed, whether semi-circular or semi-elliptical, will not only be stronger in itself, but also act less forcibly against the piers, than another arch of the same figure, span, and quantity of materials, whose voussoirs are every where of an equal length, throughout the whole extent of the arch; besides, the piers by this means being rendered intire solid stone up to high-water mark, they will be less liable to be damaged by the water forcing a way into them; a circumstance worthy notice.

But though it is easy to demonstrate that this is the best kind of construction for arches that spring at right angles to the horizon, yet to know the exact proportion in which the voussoirs ought to be increased from the key downwards, and what breadth ought to be given to the piers necessary to support them, are matters of much difficulty, and can only be ascertained from calculations founded on mechanics, and the particular properties of the figure proposed.

The theory of bridges will be rendered very clear by the solutions to the four following problems, which we shall present to our readers, as they are given by a very ingenious mathematician.

PROBLEM I. To find the nature of the extrados $V P X$ (Plate XXII. fig. 2.) of the proposed circular arch $A d Y$, such that the parts thereof shall be in equilibrio by the weights of the voussoirs alone, without the help of any wall or counterfort, provided only that the abutments be of sufficient strength to bear the weight of the whole arch.

SOLUTION. Let B be the center of the circular arch $A d Y$, AB its vertical radius, BK the horizontal one, at right angles to each other; and suppose $g d m n$, (whose joints $g d, m n$, being produced, would pass through the center B) one of the voussoirs, whose extrados $g n$ is required. Produce BA to O , so that the axis of the key-stone $Q P V Z$ may be of the given length; draw an indefinite

tangent, as CAT to the point A, the vertex of the arch. From the points d, m , (supposed indefinitely near each other) let fall upon AB the perpendiculars dF, mE ; and also dG perpendicular to mE . On B, as center with the radius Bg , describe the arch gp , intersecting Bmn in p ; let R and T be the points in which the joints Bg and Bn , intersect the horizontal line AT. The angles FdB, ARB or ATB are equal, because of the parallels AR, Fd , and the indefinitely small arch dm ; moreover, the angles FdG, Bdm , being right ones, the triangles BFd, mGd , will be similar. Put $AB=a, BF=u, Fd=y, dG=FE=\dot{u}, Gm=\dot{y}, Bg=s$, and $BO=\dot{f}$; then $BF:Bd::MG:m\dot{d}$;

that is, $u:a::\dot{y}:\dot{u}=m\dot{d}$, and again $BF:Fd::$

$BA:AR$; whence $AR=\frac{a\dot{y}}{u}$, whose fluxion

$\frac{a\dot{y}\dot{u}-a\dot{y}\dot{u}}{u^2}=RT$. Now, because $u^2+y^2=aa$, we

have $\dot{u}=\frac{-y\dot{y}}{u}$, let this value of $\dot{u}$ be substituted in

the above expression for RT , it becomes $\frac{a^2\dot{y}}{u^2}$.
